Examination of the roots of the dead plants revealed the symptoms mentioned above. The plants had died of asphyxia or suffocation. So long as the manure allowed evaporation of water from the surface-soil to take place, and atmospheric air to enter, all was satisfactory; but eventually the manure became so sodden and compact that this necessary interchange was rendered impossible, the formation of injurious organic acids in the soil was favoured, which, combined with excess of water and lack of air, resulted in the death of the plants. In the above experiments it must be added that the manure and soil round the roots was never broken up—a state of things that would not be followed by a gardener; nevertheless, the above experiment can only be considered as an extreme condition of what too frequently happens, and the final result is but a matter of time. It appears certain that plants of all kinds are, to say the least, enfeebled, if not actually killed, by an excess of water and consequent lack of air; as a proved illustration, Orchids may be cited, where the roots have been too compactly enveloped in saturated moss.

CONSERVATORY AT "THE CLIFF," SHANKLIN, ISLE OF WIGHT.—We give our readers the reproduction of a photograph by Mr. J. MILMAN BROWN of a conservatory at what was the residence of the late Mrs. HARVEY, which exhibits in its arrangements, and breadth, and the fine pieces of statuary, several pleasing features, notably, the pedestal for supporting plants in pots or vases; the different levels of the floor rendered necessary by the site, or introduced for the sake of variety, and the group of small plants at the base of the central figure. The visitor will be enabled to distinguish among the plants well-cultivated Brugmansias (*Datura*), *Cypripediums*, doubtless *C. insignis*, to the right and left of the foreground; with *Chrysanthemums*, *Dracæna australis*, *Camellia*

japonica, and Orchids in hanging baskets. We are indebted to Mr. CONN, the gardener at "The Cliff" for the photograph from which the illustration was taken.

HIGHGATE AND DISTRICT CHRYSANTHEMUM SOCIETY.—A committee meeting was held on Thursday evening, March 17, when the dates of the Floral Committee meetings for this year were settled, viz., October 31, and November 8 and 14. The Floral Committee, viz., Mr. T. BEVAN, Mr. J. BROOKS, Mr. J. BROOKS, Jr., Mr. BURT, Mr. MATHEWS, Mr. TURK, with the president, the treasurer (Mr. J. MCKERCHAR), and the secretary (Mr. W. E. BOYCE), as ex-officio members, were then elected.

DIRECTIONS FOR NAMING PLANTS.—"The best specific name is a short Latin adjective of an agreeable sound and easy pronunciation." This is what the zoologists say, and it applies with at least equal force in the case of botanists and others who name plants. They are nicest when short and sweet, serving their purpose quite as well as when long and of "disagreeable sound." It is generally a mistake, as we think, to attempt to mix up two things, a denomination or label and a description or history. The two things should be kept apart, unless in exceptional cases.

MYRSIPHYLLUM.—According to M. GEORGES TRUFFAUT, in the *Revue Horticole*, *M. asparagoides*, the "Smilax" of the American nurseries, contains a larger percentage of nitrogen than any other plant he has examined. It is also rich in chlorine and sulphuric acid. M. TRUFFAUT accordingly recommends the application of a fertiliser containing a mixture of sulphate of ammonia, nitrate of soda, and ammonia hydrochlorate [the proportions are not stated], and applied in solution at the rate of 2 grammes per litre. In subsequent years, phosphoric acid and sulphate of potash may advantageously be added to the nitrogenous manure.

MR. BARR.—On the 29th inst., Mr. PETER BARR, V.M.H., sets sail on his voyage round the world. His Daffodil-travels in the Mediterranean regions have begotten a taste for globe-trotting at a period of life when most men are best pleased to remain at home. We trust his voyage will be a prosperous one.

TERMINOLOGY.—If, says SACHS, the prejudice against descriptive botany still frequently existing, even in scientific circles, is ever to cease, it will be well entirely to get rid of superfluous nomenclature. The undesirable nature of glass-houses for those who cast stones can hardly be better exemplified. New names for old facts, or facts presented in a new light, are nowhere so abundant as in modern treatises on vegetable physiology, where new terms are constantly given to facts and phenomena without any reference to previous history or priority. Descriptive botanists are often bad enough, but they do work *secundum artem*, and with a due regard for precedence and priority; the physiologists obey no such rules.

M. FAGUET.—This celebrated botanical draughtsman has, as we learn from the *Revue Horticole*, retired from his post at the Jardin des Plantes. His drawings were as accurate as they were refined, so that they will be much missed. His successor is Madame MADELINE LEMAIRE, who is highly spoken of by our contemporary.

CAPE FRUIT.—The Union Steamship Company's vessel, *Moor*, has arrived with a cargo of Grapes and Pears, numbering 742 boxes. The first lot of 297 boxes of Grapes and 20 boxes of Pears, consigned to Mr. HUDSON, arrived in excellent condition, and were of first-class quality; the second lot of 248 boxes of Grapes, also to Mr. HUDSON, were not of the best quality, and turned out wet and nasty. The third lot, of 68 boxes of Grapes and 23 of Pears, were consigned to WOODHEAD, PLANT & Co.: the Grapes of medium quality. Number four lot to WHEATLEY & Co., 56 boxes of Grapes, were of medium quality. There were also 30 private packages. As to the wet Grapes, Mr. HUDSON says that he considers this has

FIG. 73.—VIEW IN THE CONSERVATORY AT "THE CLIFF," SHANKLIN, ISLE OF WIGHT. (SEE P. 184.)

nothing to do with the cool-chamber, but with the condition in which they were shipped. The efficiency of the cool-chamber, in this instance, is proved by the excellent condition in which the first lot of Grapes turned out.

TASMANIAN FRUIT.—We are informed by the Peninsular and Oriental Steamship Company that they have received the following "wires":—Shipments by the *Cuzco* are 10,000 boxes, and by the *China* 16,000 boxes. The *China* is due about April 9. From Melbourne we learn that the *Oruba* has shipped 6,900 boxes, the *Victoria* 10,000 boxes. The latter vessel is due about the 24th proximo.

WOOD-PULP IN FLOOR-CLOTH.—There would seem to be a fair prospect for this material in the near future. Some floor-cloth we have seen, derived entirely from pulp, gives promise of elasticity and durability. Perfect success has not yet been obtained, but those who have it in hand seem to be pretty sanguine of the result of their labours. As to taking colour, the patterns we saw ranged in shades of pale grey up to dark olive worked out in diamonds; but probably any number of tints may be retained on the wooden surface—when the composition of the fabric is perfected.

WEST INDIAN PLANTATIONS.—Everyone knows how fatal to the prospects of the Sugar industry in the West Indies the cultivation of Sugar-Beet has proved. Whether that competition be fair or unfair matters not here, we have but one instance to note here of the havoc consummated. Not long since the owners in the country of a large Sugar-growing estate in Demerara gave up competition and sold the land for one-fifth of the price originally paid for it. Since the first pound of sugar was turned out a sum of about £500,000 has been expended in machinery and the general charges incident to the working of a big concern; of course, this has not been lost, but we do not know that profit has been made commensurate with the outlay. We are informed by a correspondent that a member of the firm retired from sugar-growing, is now in Louisiana trying to make a good bargain for the splendid machinery now lying idle, and which would not be taken to by the purchaser of the land. Pity 'tis, 'tis true.

WOOD PULP FOR PAPER.—The requirements of the paper trade, according to a paper read recently before the Society of Arts, are likely to become a great drain upon the forests of Scandinavia, the United States, and Canada. Judging from the present rate of increase, the quantity of wood required will, before long, assume enormous proportions. It was estimated a few years ago that in the United States of America alone 500,000,000 cubic feet of timber were consumed annually, representing the destruction of 100,000 acres of forest. It was also estimated that each day the *New York World* consumed timber equal to seven acres of an average forest. The world's timber suitable for paper-making is not inexhaustible, and we may some day be in a position in regard to wood as this country was at the end of the last century in regard to the supplies of rags.

THE NATIONAL CHRYSANTHEMUM SOCIETY.—The adjourned annual meeting on Monday last was prolonged to a late hour of the night, and considerable interest, which occasionally showed itself in heated discussion, characterised the proceedings. Under the circumstances, the decisions arrived at by the meeting were in many respects the best that could be made. The committee permitted the expenditure during 1897 to exceed the income, but at the annual meeting three weeks ago, owing to the wise councils of Mr. GORDON and others, it was resolved to face the matter fairly, and hence the financial statement was referred to the committee, who were instructed to pay all debts contracted during the year, instead of carrying some of them over, and thus showing a false reserve fund. This was done, the reserve fund being thus reduced by about £50. Such being the case, it was the imperative duty of the members to pass the

accounts as amended. They might well regret the necessity to touch the reserve fund, but at the same time they have acted honestly; and in the future, we doubt not, there will be greater supervision exercised over the expenditure. Already the estimates for the present year have been modified to such an extent that a balance of £22 8s. in favour of the receipt is indicated, and this has been done by reducing the money offered as prizes at the exhibitions. The committee should also be able during the season to effect considerable saving in minor matters. It was decided to appoint a general secretary, at a salary to be fixed by the committee, and that in future the secretary will be an officer of the Society without the privilege of voting. Considerable opposition was made to the re-election of Mr. R. DEAN to the position, and many charges have been made against him. But it appears to us that the committee are to blame in a greater degree. Instead of attending to matters themselves, they have permitted the Secretary to manage them single-handed. The committee is or should be the governing body, but if its officers dictate to the committee its policy, then the members are sadly wanting in business qualities. Now that the Secretary's position is to be clearly defined, the re-election of Mr. DEAN is the best that could have been done. Mr. R. BALLANTYNE, the new Treasurer, will have no difficulty in at once assuming the duties as well as name of his office. Most of the other officers being re-elected, the society ought soon to be in better working condition than for some time past. Several amendments were made to the revised rules, which will tend to the society's welfare. There are many questions the new committee will have to face, including the opposition there still exists to holding the exhibitions at the Aquarium, and the policy of reducing the number of shows by omitting at least the one usually held in September. In any case, whether the exhibitions are held at the Aquarium or elsewhere, we hope that on no future occasion will the most convenient space in the building be let to "sellers of sticks and manure," as one member stated, and the Chrysanthemum-blooms be relegated to the galleries.

AN APPEAL TO MASONS.—In connection with the coming election in May next of pensioners to the Masonic Benevolent Institution, we have received from Mr. W. NAPPER the following appeal on behalf of the widow (aged 60 years) of the late Dr. W. R. WOODMAN, P.G. Swd.-Br. (Eng.). Dr. WOODMAN was a very respected member of the nursery trade in Exeter, and we doubt not his widow will be given cordial support by our readers who happen to be Masonic nurserymen or gardeners. "Dr. WOODMAN was initiated in St. George's Lodge, No. 112, Exeter, in the year 1852, and was a P.M. and for eighteen years a member of No. 441, Starcross, Devon. He was a P.M. and for thirty-three years a member of Grenadiers Lodge, No. 66, London. For six years a member of "Britannic," No. 33, London, and also a member of other Lodges. His membership of Chapters was equally long and valuable. He was also a member of the K.T. and R.C. degrees. He was a Governor of the R.M.B. Institution, as well as that of the R.M.I. for Boys, and a Vice-Patron of the R.M.I. for Girls, having served several Stewardships. At his death in 1891, his widow found herself absolutely penniless."

TITMICE.

(Concluded from p. 96.)

WE now come to three species of tits that are undoubtedly useful to agriculture, because they are not only more numerous than the other members of the same family, but they live near human habitations, and are found in every garden and orchard. In this trio the first place may be given to the great tit. The great tit is a voracious devourer of insects of all kinds and in all stages. Yarrell remarks that it is indefatigable in search of food, and, being fearless in disposition, it may be readily observed climbing the trunks of trees, or hanging suspended from the under surfaces of branches while examining every

cavity, leaf, or bud that is likely to afford shelter to any of its numerous insect-prey. This description of its habits is corroborated by Seebohm. Late in the autumn, small seeds and fruit form part of its diet; but, according to the last-mentioned authority, its young are fed entirely on small caterpillars and grubs. The French naturalist, Brocchi, in his *Traité de Zoologie*, says:—"Knowing the habits of these birds, it is easy to understand that they should be ranged among the best helpers of agriculturists, who sometimes entice them to frequent orchards and gardens by making artificial nesting-places." Brocchi mentions also that on a certain property where the fruit-crop was regularly devastated by insects, tits were attracted by artificial nests distributed in great numbers throughout the orchards, and that after the arrival of these birds the crops were abundant.

The great tit (*Parus major*) is a beautiful bird, about 6 inches long, and usually builds its nest in holes in walls, trees, decayed posts, and similar places. Its head and throat are glossy-black, with a white patch under each eye. Its back is olive or ashy-green, and the body underneath is greenish-yellow, with a broad stripe of black down its entire length.

Not less beneficial is the long-tailed tit (*Parus caudatus**), which is common in the south and south-western counties of England, but not so common in the north. It is about 4½ inches long, and sometimes builds a most elaborate nest, shaped like a bottle, from which this bird is known familiarly in some localities as the "bottle tom-tit;" the nest, which is built in thick bushes or dense shrubs, has a very tiny hole in the upper part of the side, and the eggs vary in number from ten to sixteen. Yarrell holds that this bird is more decidedly insectivorous even than the other species of tits. Seebohm also remarks that its food is chiefly composed of insects, but that it also eats small seeds of various kinds, as of grasses and of the Birch. Brocchi maintains that it feeds entirely on insects in France, and that it and all the species of tits have a right to the protection of agriculturists, to whom they render important services. He estimates the annual consumption of each of these birds at nearly 200,000 insects in the form of eggs and larvæ, and remarks that when they attack the buds of fruit trees, an offence with which they are sometimes charged, it is certain that there are insects within these buds.

The head, breast, and neck of the long-tailed tit are whitish, with black bands or stripes. The back is black, and the wings and the very long tail are black edged with white.

The blue tit (*Parus cæruleus*) is the most useful of all the tribe of tits, a pretty little bird, about 4½ inches in length, and happily distributed generally throughout the country. The wings and tail of this species are blue, the breast and belly sulphur-yellow, the back yellowish-green, and the side of the head white, with a blue band running across it from the beak to the nape. Its nest of moss, hair, and feathers is built in holes in trees, walls, or gate-posts, and sometimes in pumps, letter-boxes, and other extraordinary places. Insects appear to be the principal objects of its search during the summer. Naturalists who have watched these birds, saw nothing but small grubs and caterpillars brought to the young ones from Apple-trees near. In the winter this tit feeds upon seeds, eggs, and pupæ of insects, and anything it can pick up. The hen-bird lays from eight to fourteen eggs.

In a report published by the Massachusetts Board of Agriculture upon that most destructive insect, the gypsy-moth, allusion is made to the services of titmice in Europe.

The writer of the report says:—"In Europe there are six different species of titmice. All of them are found in some of the countries where the gypsy-moth is native. They are all recognised as eminently beneficial, and are regarded by foresters, entomologists, and ornithologists as among the most useful species in controlling noxious insects. Could they be

* Some naturalists have placed this bird in a separate genus—*Acredula*; others keep it in the genus *Parus*.

successfully introduced here, they might do a vast amount of good, not only in destroying the eggs of the gypsy-moth, but their larvae also, as well as the eggs of many injurious insects."

In a bad attack of gipsy-moth in 1848, in Germany it appears that all the trunks and branches of the trees on a certain estate were covered with the egg-clusters of these insects. It was a useless task to attempt to remove them by hand, and the trees were not expected to survive. Towards the winter, however, numbers of titmice and wrens came daily to the trees, and the egg-clusters disappeared. In the following spring twenty pairs of titmice nested in the place, with the result that the plague was noticeably reduced, and a year later the birds had cleared off the insects to such an extent that the trees had entirely recovered their former vigour.

These useful little birds, the tits, do not appear in the schedule of the Wild Birds' Protection Act of 1880. Some species, however, have been added to it in a few counties of England. The eggs of some are also protected under the Act of 1894 in a few counties. In the counties of Northumberland, York (E. Riding), Cambridge, Chester, Norfolk, East Suffolk, Devon, Essex, Kent, Isle of Wight, the eggs of all the species of tits are protected in the specified breeding areas. Both the birds themselves, as well as their eggs, deserve to be preserved. *Board of Agriculture, 4, Whitehall Place, S.W.*

CULTURAL MEMORANDA.

DIPLADENIAS.

THE merits of this handsome genus of stove-flowering plants are not now so thoroughly appreciated as they deserve to be, which may be due to the insufficient reason that they are especially subject to the attack of mealy-bug (*Coccus adonidum*).

For cutting purposes, *Dipladenia* flowers are of great value, and continue fresh for a length of time in water; whilst for training up pillars and rafters the plants are most appropriate. Many of the species also make grand specimens for exhibition purposes. When grown for the latter purpose, they should be trained upon balloon-shaped trellises at the time of potting; but as the young growths lengthen, these should be adjusted to strings stretched up the roof about 9 inches from the glass, to be taken down and dispensed evenly over the trellis a short time before the plants are required for exhibition.

During the growing season, these plants require a temperature of 75° to 85°, and a very humid atmosphere. If the cultivator has convenience for plunging them in a bed of tan or other suitable material, this will be an advantage.

Early in the month of February is the best time to repot the plants; and a compost of equal parts of peat and fibrous loam, a small portion of dried cow-manure, finely-broken charcoal, and an abundance of silver sand added will suit them well.

A point of much importance to the successful cultivation of these plants, is the provision of ample well-placed drainage materials; the pots also should be quite clean, if new all the better, providing they have been soaked in water previously, and thoroughly dried before using.

Care should be taken when removing the old soil not to disturb the roots more than necessary, pricking it out carefully with a pointed stick, until sufficient has been removed to allow of about 2 inches of new soil to be added round the sides of the ball. The collar of the plant must on no account be buried more than half-an-inch below the surface.

Water should be afforded with care at all times, and when the plants have finished their growth, they should be removed to a cooler and drier house, having a temperature of about 60° to 65°, and that is fully exposed to the sun's rays, so that the wood may become thoroughly ripened, and at this time water must be gradually withheld, very little being required during the winter season.

The following is a selection of six of the best varieties:—

D. Brearleyana is the most beautiful of all the *Dip-*

ladias, the individual flowers measuring from 4 to 5 inches across, and they are of a rich pink, changing with age to crimson.

D. Williamsii produces abundant flowers in large clusters, colour soft pink, with rose-coloured throat; very distinct and beautiful.

D. profusa is a distinct, vigorous species, and one of the most floriferous, the flowers being of great substance, and 5 inches in diameter; colour, rich carmine.

D. nobilis is also very handsome, freely producing immense clusters of rosy-purple flowers, that with age change to red.

D. amabilis is one of the finest for exhibition purposes, and continues a considerable time in perfection, the colour of the flowers somewhat resembling *D. Brearleyana*.

D. boliviensis.—Unlike the others, it produces small and abundant white blossoms, the throat being of a bright orange colour. This plant is easily cultivated, and succeeds best in small pots. I have found this *Dipladenia* to be comparatively free from mealy-bug. The foliage is light green in colour, with a smooth surface. *H. T. M., Stoneleigh.*

COLONIAL NOTES.

QUEENSLAND.

AT this season of the year when there is a disposition on the part of the surplus population to think of making a move to other lands, I venture to bring before your readers some of the advantages which the colony of Queensland offers to emigrants from the old world. There has been a splendid rainfall this season throughout the colony, which will have the effect of expanding trade and industry in all departments of work, and coincident with this there is a remarkable movement in agriculture setting in.

There is still much undeveloped wealth slumbering in Australian soil. Fifty years hence, according to the *Australasian Review of Reviews*, the Darling Downs in Queensland may well be the garden of Australia. The Downs are an undulating table-land, about 2,000 feet above the sea-level, with the main line from Sydney to Brisbane running through them. They have an area of something like 4,000,000 acres of the richest agricultural soil in the world—soil ranging from 10 to 60 feet in depth, and as fertile as the Delta of Egypt or the river bottoms of Siberia.

When delegates from the Wholesale Co-operative Society were visiting the Darling Downs in 1896, it was explained to them that there were gold mines in the neighbourhood. "Ah," said they, "you have something better than gold mines here in these stretches of agricultural land which ought to be covered with dairy herds or sown to wheat." Progress is being made in this direction, and Queensland is now a regular exporter of butter to the home market, where it stands in the front rank as regards quality.

Although there is a wide and promising field in Queensland for the unskilled labourer, and the tradesman or artisan whose ambition is bounded by the possession of a steady and well-paid job, the conditions of the colony at the present time are such as to present far stronger inducements to the tenant farmer, the small working capitalist, the man who is determined before all things to be the architect of his own fortune, the owner of his own house and land in fee simple.

A Land Act was passed last December, some of the main features of which are concerned with placing the acquisition of land upon more liberal and convenient conditions. Briefly, Government land may be taken up on the following easy terms:—

Agricultural Homesteads.—The area to be selected varies with the quality of the land, the maximum being 160, 320, and 640 acres, according to class, at 2s. 6d. per acre, payment extending over ten years; personal residence is necessary, and improvement to the extent of 10s., 5s., and 2s. 6d. per acre, according to the size of the farm, has to be effected. Labour of any kind on the land, such as building, clearing,

fencing, or breaking up of the soil, counts as an improvement.

Agricultural Farms.—Area up to 1280 acres at 10s. per acre upwards, payment extending over twenty years.

Grazing Selections.—Farms and homesteads in areas up to 20,000 on fourteen, twenty-one, and twenty-eight years' lease, at an annual rent of $\frac{1}{2}$ d. (one halfpenny) per acre upwards.

Scrub Selections.—These are divided into four classes (according to quantity of timber on land to be cleared). Area of each up to 10,000 acres, lease for 30 years. No rent for first 5, 10, 15, or 20 years, according to class; remaining periods, $\frac{1}{2}$ d. to 1d. per acre per annum.

Unconditional Selection.—Areas up to 1280 acres; the purchase of the freehold being from 13s. 4d. per acre upward, payable in twenty annual instalments.

Agricultural Lands Purchase Acts.—Large freehold estates or choice agricultural land are also being bought by the Government, surveyed into farms ranging from 40 to 640 acres in various favoured localities, for the purpose of bringing about close settlement. These lands are sold on an extended payment of 20 years, and become the freehold by payment practically of £7 19s. a year for every £100 of the purchasing price. Should the purchaser desire to secure his freehold earlier, he can do so by paying the remaining instalments of principal, together with one-quarter per cent. for interest.

Steady progress is shown in the development of the resources of Queensland. The gold production advanced 25 per cent. for 1897; the total return of the gold won up to date is about £42,000,000. The productions of the colony have an extensive range, owing to its vast area and varying climate; they include the cereals and fruits of the temperate zone; sugar, coffee, and the like, from the tropical northern coast; and wool, hides, and frozen meat from the sheep and horned cattle. The climate is healthy, with a low death-rate; there is an excellent school system in the colony, without fees or religious restraint, with many promising avenues for young people, and the general community are enlightened and well to do.

I shall be happy to afford full and detailed information to all inquirers. *Chas. S. Dicken, Acting Agent-General, Queensland Government Office, Westminster Chambers, 1, Victoria Street, London, S.W.*

GATHERING FLOWERS OF NARCISSUS FOR MARKET IN SCILLY.

OUR illustration (fig. 74) of gathering *Narcissus* in one of the Scilly Islands affords an excellent idea of the profusion with which the bulbs flower in the favoured maritime climate of the islands. No wonder that the exports to the "adjoining island" can be reckoned, in the height of the season, at 20 to 30 tons per day; and, that the islanders enjoy a degree of prosperity that was unknown in the old days of the exclusive culture of early Potatoes.

HOME CORRESPONDENCE.

THEN AND NOW.—Looking through Evelyn's *Kalendarium Hortense*, or *Gardeners' Almanac* (first edition, 1664), my attention was attracted to his monthly list of "flowers in prime or yet lasting" in connection with the present early season. His list for January follows:—Winter Aconite, Anemones, Winter Cyclamen, Black Hellebore, Brumal Hyacinth, Oriental Hyacinth, Levantine Narcissus, Hepatica, Primroses, Laurustinus, Mezereon, Præcoce Tulips, &c. But he adds, "especially if raised in the hot-bed." Without this last clause, the list, which is given under the heading of "The Parterre and Flower Garden," would be perplexing, even when we allow for the old style in dating; yet with it one wonders why the list was not extended. Almost the same list is given for December, without any such explanation, though it is plain it should be understood, as *Yucca*, *Iris Clusii*, and Stock Gilliflowers are also included. Anemones appear in the lists from November to May, so it is evident that some method of forcing was practised. And on turning

to the instructions for November, we find the following:—"If the season prove exceeding piercing (which you may know by the freezing of a dish of water set for that purpose in your greenhouse), kindle some charcoals, and then put them in a hole sunk a little into the floor about the middle of it. This is the safest stove." If that was the safest way of heating, great results could not be expected. Manure-water he designates "qualified water." There are many interesting and quaint things in this Almanac. The variety of fruits in the monthly lists is greater than one would have expected, but Grapes are only named under August and September. On the other hand, Apples and Pears are enumerated under each month. Tobacco is included among the seeds to be sown in March; yet I find no further reference to its cultivation or preparation. The Narcissus of

it; especially if with this be considered likewise the casualties in planting it, as seldom succeeding more than once in three years; yet requiring constant changes and culture; besides that it is none of the least devourers of young timber." *W. Botting Hemsley.*

DRACÆNA IN THE SCILLY ISLES.—In your fine photograph of *Cordylina australis* in the *Gardeners' Chronicle*, p. 153, you leave out "Hamlet" in your short description. The photograph is very fine, and most remarkable as showing *C. australis* in flower and the rare and beautiful *C. indivisa* (vera) side by side, whereas people will persist in muddling up the two plants and the two names. *C. indivisa* at Tresco flowers and fruits now and then, but I cannot rear its seeds either from Tresco or from New Zealand. *P. W. B.*

for my application from what is called a business-like firm. Is this usual? *W. A. S.*

ALSTROEMERIAS AS POT PLANTS.—Perhaps the less hardy of these tuberous-rooted plants are not grown in pots to the extent that their merits deserve. But given their few requirements the result will be nice bushy plants with an abundance of flowers, the colours and markings of some of which rival those of Orchids. The roots may be obtained in the autumn, potted into suitably sized flower-pots, in a compost consisting of loam, peat, leaf-mould, and sharp sand, placing the plants in a cool frame, and protecting them from heavy rains and frost. When growth ensues, place the plants in a cool airy house, close to the glass, for, if kept in a frame at this time the shoots and thick fleshy leaves of the plants are liable

From a photo by R. H. Preston, Penzance.]

FIG. 74.—GATHERING NARCISSUS BLOOMS IN SCILLY. (SEE P. 186.)

Japan or Guernsey Lily is designated "that rare flower." Directions are given for making cider and perry, but not for making wine. Indeed, the same volume contains a lengthy treatise on making cider, the work of several contributors, which was "published by express order of the Royal Society." Cider is extolled at the cost of malt liquor. The following long and curiously printed and pointed sentence explains itself. "It is little more than an age since Hopps (rather a medical than alimental vegetable) transmuted our wholesome ale into beer; which, doubtless, much altered our constitutions. That one ingredient (by some not unworthily suspected) preserving drink indeed, and so by custom made agreeable; yet repaying the pleasure with tormenting diseases, and a shorter life, may deservedly abate our fondness to

THE DAFFODIL BLOOM OF THE UNITED KINGDOM.—Will some of your readers kindly say whether quantity of the blooms is this year above or below the average. With me in Ireland, and in the Scilly Isles, as I am told, the flower crop is but one-quarter of the usual quantity. I suppose the cold spring of 1897 and so much rainfall had something to do with the poor bloom of the present year. *Telamonius Plenus.*

ANSWERS TO ADVERTISEMENTS.—An advertiser had an advertisement in the *Gardeners' Chronicle* for a man to take charge of a certain department. I answered the advertisement in a business-like way, enclosing a testimonial. After a lapse of about fourteen days, I received my testimonial partly destroyed, with not even as much as a word of thanks

to suffer from damp. In the spring return the plants to a cold pit with a cinder floor, and later plunge the pots in coal-ashes on an outside border, sheltered by a wall. After flowering and when the stems die down afford but little water, and afterwards shift them into larger pots as may be required, and grow on as before. The following varieties are sometimes grown in pots: *A. pelegina*, *A. p. alba*, *revoluta*, *pulchella* (*Simsii*), *tricolor* (weak in the stem), *pallida*, and *hæmantha*. *James Baxter.*

CROCUSES AND SPARROWS.—With reference to that part of Dr. Bonavia's letter relative to Crocuses, I find it is usually the earliest that the sparrows attack, which in most instances are yellow ones, but that they do not spare purple ones if they happen to be early. I further notice that the flowers in borders

which the early morning sun reaches are those attacked. I have had to protect the blooms, whether yellow or other colours; but three beds edged with yellow Crocuses which do not have any sun on them till late in the forenoon, are not touched, and they are not protected. I have also two borders facing S.E., but have a cat that is fond of sitting on a window-sill or basking under a bush, so the Crocuses there are quite safe. I protect my borders with black thread fastened on to twigs, put in the ground, and find it an effectual protection. I do not find the flowers attacked much after they are in full bloom, but that the blackbirds also share in the mischief. With reference to "R. D.'s" communication, I have a border of white, purple and striped Crocuses which stand the storms very well, but they are protected from the north. I strengthen them by adding those I have had in pots the year before, and as the colours are such a contrast to all yellow varieties, they are I think well worth growing. Any which have large cups, or grow higher than others, suffer from rain and wind—yellow as well as other colours, and those I have on a bank topple over, so I have given up putting in any more. Do not mix yellow with other colours, the first come up too early and spoil the arrangement. *Tilson Lee, Woodside, Redhill.*

ARAUCARIA IMBRICATA.—I enclose for your inspection seeds of the *Araucaria imbricata*, gathered from a tree growing in the grounds at Tillingbourne House, near Dorking. Is it not unusual for this tree to fruit in England? We have in the grounds here, at Bury Hill, several very fine specimens of the *Araucaria*, but hitherto none have shown any signs of bearing fruit. The workman who brought me these seeds assured me that the tree was not at all a large one, but no doubt it may be of some considerable age. *James Shaw, Gardener, Bury Hill Gardens, Dorking.* [The production of cones is not very uncommon, and we have notes of ripe seed from Basing Park, Hants, Drinkstone Park, Bury St. Edmunds, Totworth Court, Gloucestershire, &c. Ep.]

GARDENIA CULTURE.—Your correspondent, "J. E.," in a recent issue on p. 157, states his experience of repeated failures in the cultivation of Gardenias, and though he did not look to me for the information he desires, it may be helpful if I relate my own experience, which for two years was similar to that of "J. E." Finding that the canker appeared on the older or two-year-old plants, I ceased to attempt to grow them, and obtained the necessary supply of flowers from young stock, which, by the way, produce much finer blooms. Before owning myself beaten, I resolved to experiment upon a few plants after they had flowered, and accordingly retained a number of the healthiest in the batch, and I may say that this particular stock was quite free from canker. Half the number were cut down to from 4 to 6 inches from the pot, while the remaining half had simply the longer shoots cut back to a uniform length; these latter were at once potted up into larger-sized pots, and the cut-back plants as soon as growth had commenced. The soil in both cases was identical, and the treatment throughout the season was precisely the same, but the cut-back plants never made much headway, and even when at their best, lacked that dark-green tint indicative of health. By August, canker had again made its unwelcome appearance, and upon examining the roots they were found to be literally a confused mass of miniature "clubs." [eel worms?] The flowers on such parts of the plants as escaped injury were puny, and the colour more like an exhausted bloom than one freshly opened. The plants that were less severely pruned gave an excellent return in quantity of bloom, but the size of each was less than that of blooms from the yearling stock; and as the structure which I had decided to devote to Gardenias was unsuitable for any but dwarf plants, I have since only grown stock to give me one crop, and afterwards propagate afresh. Occasionally we retain a few when our batch of young stock is limited, and in no case have I found any signs of canker when they have not been severely cut-back. Our treatment, I believe, is not exceptional, but a brief account of same may not be uninteresting to "J. E." and to other readers of the *Gardeners' Chronicle*. Cuttings are put in as early in January as strong shoots can be obtained. Three-inch pots are used, and the cuttings are placed round the sides. The compost is of silver-sand and peat in equal parts; the latter having been passed through a fine sieve makes a suitable rooting medium. A close case, having the advantage of a smart bottom-heat, is very

convenient, as it greatly facilitates the rooting process. As soon as each cutting is furnished with a few roots they are potted singly into thumb-pots, using two parts peat in slightly rougher form, and one of leaf-soil, also some sand and broken charcoal. We use clean pots and afford ample drainage. The plants are again placed into the propagating-case, and they remain there until the roots penetrate the fresh soil, when they are taken out and stood near the glass in the propagating-house. In about a month from the time of potting, the points of the shoots are removed to induce the formation of suckers, and a number of side branches. When the plants have recovered from this check, they are placed into 5-inch pots; the soil which is used on this occasion being somewhat similar to that previously stated, except that a small addition of fibrous loam is made, and a sprinkle of Thomson's Vine and Plant Manure. Firm potting is practised, and the plants are again pinched twice during the growing season, once in May, and again in July. The back of a hip-span-house in the front of which Crotons for table service are grown, is the site where the Gardenias are grown, and the structure is scarcely ever ventilated, but when the sun becomes too powerful, a very thin shading is pulled down over the Gardenias, and the plants and all surfaces are well syringed. In summer-time, we not infrequently run the blind up and syringe overhead with the glass standing at 115° at 2 P.M. The temperature is lowered considerably in October, and all growths being completed less water is given, and a season of comparative rest afforded. During this period buds are formed, and as we have had to supply flowers during March and April, the plants have not been hurried into growth by affording a higher temperature before February. The average number of blooms to a pot when the plant has been well grown, has been two dozen. After the pots were fairly charged with roots, we have given Clay's Fertiliser and Ichemic Guano alternately, and these are the best stimulants for Gardenias I have yet tried. *J. F. McLeod, Roehampton.*

HARDY PLANTS FOR FURNISHING FLOWERS FOR CUTTING.—In reply to Mr. E. Jenkins' remarks on p. 173, I admit I should have been more explicit in my statements respecting *Alstroemerias* out-of-doors. I ought to have stated in my note (p. 156), that pot-plants should be obtained wherewith to make fresh plantations instead of divided roots, for the reasons given by your correspondent. Even for early autumn planting, plants established in pots are preferable. A simple method of raising a stock of the *Alstroemerias* named in my list is to sow seeds in drills, 3 inches deep and 18 inches apart, placing the seeds in patches of three or four 1 foot apart. If seed be sown this month or early in April, the seedlings should begin to bloom about fifteen months afterwards, and they will increase in strength and floriferousness year by year, providing they are not injured by frost, and that a mulch of leaf-soil or half-rotted manure be laid on late in the autumn will prevent. The spent-flowers should be cut off in order to prevent seed-bearing, the stems not being shortened, or the leaves removed, but all of these allowed to die down, they being naturally necessary to the proper ripening of the tubers, and the formation of new crowns. My authority for stating that large quantities of *Alstroemerias* are grown for supplying wholesale florists in Covent Garden is Mr. T. S. Ware, of Tottenham, a high authority on the subject of choice hardy perennials, who says, "some are grown in large quantities for supplying Covent Garden;" adding, "that although natives of Chili, they are quite hardy, and thrive well in our climate." Another good authority on choice hardy perennial flowers—Mr. H. J. Elwes—writing of the genus *Alstroemeria* in the *English Flower Garden*, on p. 10, says:—"Anyone having deep light sandy soil resting on a dry bottom, may grow these beautiful flowering-plants without any artificial preparation; all that is necessary in that case being to pick out a well-sheltered spot, but to give the surface a slight mulching on the approach of severe weather;" adding—"No trouble is involved in staking and tying, as with most plants, for the stems of these are quite strong enough to support themselves, unless in very exposed situations. Independently of the handsome bloom which they make when growing, they are quite worth-cultivating for supplying cut flowers, and they last long when cut." Thus it would appear that, apart from my own experience of the *Alstroemeria*, that I am justified in including *Alstroemerias* in my list. When I wrote in the *Gardeners' Chronicle* of March 12, p. 186, "Large quantities of *Alstroeme-*

rias are grown for Covent Garden," I purposely refrained from mentioning varieties in connection therewith, not being sure whether a sufficient number of plants of, for instance, *A. pelegria alba*, for growing in quantity was available in the time that has elapsed since the plant was accorded a First-class Certificate at a recent Temple Show, and so did not specify the varieties in case I might be doing an injustice to *A. pelegria alba* by excluding it from the list. Under these circumstances I regret being unable to give Mr. Jenkins the name of a place in England in which *A. pelegria alba* grows in the open air in quantity for market purposes. Perhaps some readers of the *Gard. Chron.* may be able to mention the name of a place where the plant succeeds in the open, not necessarily in quantity, or for market purposes. My own opinion is, that once this plant gets well-established in a lightish kind of soil, and a somewhat shady position, it will flower as freely as *A. aurantiaca*, *A. pelegria* and other free-growing varieties. With the editor's permission, I shall have something further to say in regard to English and Spanish Irises, and double-flowered Daffodils, also included in my earlier communication on "Market Plants." *H. W. Ward, Rayleigh.*

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 22.—An excellent display was made in the Drill Hall on Tuesday, on the occasion of an ordinary meeting of the committees, and the attendance throughout the day was large. The greater number of the exhibits were such as are dealt with by the Floral Committee, and included fine displays of *Hippeastrums*, *Cinerarias*, *Cyclamens*, *Roses*, *Hyacinths*, *Cliveias*, *Ferns*, and a few hardy plants. One of the chief characteristics of the display consisted in the uncommonly good cultivation evidenced in some of the large exhibits. The Narcissus Committee was presented with several large collections of flowers, the warmer weather prevalent since the last meeting having brought these flowers on considerably. Very little indeed was placed before the Fruit Committee, but it was not so in the case of the Orchid Committee, which was asked to inspect some exceedingly choice *Odontoglossums* and other species. The weather, in the morning particularly, was not at all favourable, and a rather thick fog prevailed, so that sufficient light to perfectly show the tints of colour in the flowers was unable to penetrate the Drill Hall. A lecture was delivered during the afternoon by Mr. J. Willis on "Soils," a digest of which will be found below.

Floral Committee.

Present: W. Marshall, Esq., chairman, and Messrs. C. T. Drury, H. B. May, R. Dean, Ed. Molyneux, Geo. Stevens, J. F. McLeod, R. B. Lowe, J. Jennings, C. J. Salter, H. Selfe-Leonard, J. Fraser, J. D. Pawle, Chas. E. Shea, Chas. E. Pearson, F. W. Sanders, E. F. Cook, E. Beckett, Herbert J. Cutbush, O. Thomas, Ed. Mawley, J. W. Barr, H. J. Jones, Harry Turner, Geo. Paul, W. Howe, Jas. Hudson, D. B. Crane, Geo. Gordon, Chas. Jefferies, and Jas. Walker.

The attendance upon this committee was exceptionally large; as will be seen from the above names, there were thirty-one members present.

An Award of Merit was recommended to *Hyacinth*, City of Haarlem, flowers single, large, and pale yellow in colour, spike bold, and densely flowered. This, and a large group of *Hyacinths* in pots, were shown by Messrs. W. PAUL & SON, Waltham Cross Nurseries, Herts, in whose collection there were over 200 pots. The plants exhibited excellent cultivation and great variety, being one of the finest exhibits of *Hyacinths* we have observed for some years past (Silver gilt Medal).

An Award of Merit was recommended to *Cordylina* *Exquisita*, a very beautiful variety in the way of Cooperi, but with more recurving foliage and slightly broader. It was shown by Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, Chelsea, who had half a dozen plants. Messrs. VEITCH were recommended Awards of Merit also for *Hippeastrums* *Ideala*, *Clonia*, and *Tacola*, each of these varieties had very prettily marked flowers, the lightest coloured and most delicate looking being *Clonia*, but a slight edging of very bright scarlet to each segment was very effective. *Rhododendron indicum* var. *Kämpferi*, a Japanese species, exhibited from Chelsea, also had rose-coloured flowers of *Azalea* form.

J. VEITCH & SONS, showed a large number of *Cliveia* *miniata* in much variety, for which a Silver Flora Medal was awarded. Every truss was remarkable for its large size, and each showed some differences in build, in the number of the flowers in a corymb, and in shades of colour, no two being exactly alike. Some were seedlings not yet rejoicing in a name. Of named ones we may mention *Optima*, a very large flower and truss, receiving an Award of Merit; *Admiration*, extra fine in colour, size of truss, and form of flower; *Niobe* and *Favourite*, of a pale orange hue. At the rear of the group stood five pyramidal

plants of *Pyrus atrosanguinea*, with flowers of an apple-pink shade when expanded, and of bright carmine in the bud. This firm showed small plants of *Corylopsis pauciflora* in bloom; also several of *Clematis Nelly Moser*, having flat flowers of a bluish colour, with a rosy-red band running down the centre of each petal. *Lindera sericea*, a woody shrub, with axillary bunches of greenish inconspicuous flowers, and *Shortia galacifolia* formed part of this exhibit.

Messrs. J. JAMES & SON, Woodside, Farnham Royal, again displayed their celebrated strain of *Cinerarias*, in a group of plants of very dwarf habit, with comparatively small foliage, and flowers about 4 inches across—smaller, of course, in the cases of dark self-coloured varieties. The colours were not less remarkable than the size of the blooms and the habit of the plants, for whether self-coloured or bicoloured, all the flowers exhibited superlative quality, and richness of tint. The bicoloured or oculate flowers greatly increased the brightness of the group, but the self-coloured ones are quite as attractive, by reason of their richness, and these as well as the bicoloured flowers are beautifully imbricated (Silver-gilt Medal).

Mr. JNO. R. BOX, West Wickham and Croydon, also exhibited a group of *Cinerarias*, very commendable in habit, and in the brilliant colouring of the flowers.

An Award of Merit was recommended to an *Azalea obtusa*, shown by W. NICHOLSON, Esq., Basing Park, Alton (gr., Mr. W. Smythe). This is a small-flowered, magenta-coloured *Azalea*, reminding one of a larger flowered *A. amœna*.

Mr. MOUNT'S ROSES were more magnificent than ever, H.P.'s, as well as T.'s and H.T.'s, being of extraordinary quality for forced flowers. Catherine Mermet, a favourite at the Canterbury Nurseries, was again conspicuous, one bloom in particular being of uncommon size, but a trifle pale in colour. La France, Comtesse de Nadaillac, amongst the Teas, were noted. Of the H.P.'s, the fine variety, Mrs. John Laing, was exhibited in greatest quantity; but Ulrich Brunner, Captain Hayward, and many others, were represented by exquisite blooms (Silver-gilt Medal).

Mr. W. RUMSEY, Joyning's Nursery, Waltham Cross, made a large display also with Roses, showing about a couple of hundred blooms. The majority of these were Teas, and *Maréchal Niel*, *Niphetos*, *The Queen*, *Souvenir d'Un Ami*, and others were noticed very fine. Of H.P.'s the new Mrs. Rumsey was shown well, and *Comte Raimbaud*, *Chas. Lefebvre*, *Baron de Bonstetten*, and others (Silver Flora Medal).

Messrs. WM. PAUL & SONS, Waltham Cross Nurseries, Herts, exhibited three pretty groups of Roses in pots. Two of these were composed exclusively of the variety *Enchantress*, a pretty pale flesh-coloured Tea. The third group contained such varieties as *Sylph*, *Madame Jules Groley*, a pretty rose; coloured H.T.; *Souvenir du Président Carnot*, also a H.T. of much merit; and others.

Messrs. W. CUTBUSH & SON, Highgate, London, contributed a group of miscellaneous plants, inclusive of *Thyracanthus utilis*, a number of dwarf plants of *Malmaison Carnations*, *Richardia Elliottiana*, *Acacia Drummondii*, &c.

Cyclamens exhibited by the ST. GEORGE'S NURSE & CO., Hanwell, W., were of splendid quality. Their group included about ten dozen plants rather larger and older plants, and carrying a far greater number of flowers than those shown at the last meeting. A white-flowered variety, with beautiful frimbration, and the normal *Cyclamen* form is very pretty (silver-gilt Medal).

Hippeastrums were again shown by Captain HOLFORD, Westonbirt, Tetbury, Glos. (gr., Mr. A. Chapman), who staged upon this occasion a group inclusive of many more plants than at last meeting. These seedling varieties in many instances were of great merit. An Award of Merit was recommended by the Committee to one named *Beacon*, a self-coloured crimson variety of much substance (Silver-gilt Medal). Captain HOLFORD also showed a few plants of *Sonchus laciniatus*.

Messrs. R. & G. CUTBERT, South gate Nurseries, Middlesex, contributed a fine group of Tulips in pots, a most creditable collection of well cultivated plants. The varieties of Tulips have changed so little of late years that it is unnecessary to specify those shown, though they were very representative.

Messrs. B. S. WILLIAMS & SON, alongside a group of Orchids, noticed elsewhere, staged a dozen or so plants of *Azalea mollis*, also of *Staphylea colchica*, *Hippeastrums*, and a few *Cliveias*. Their *Cliveia Oriflamma* was very fine.

Mr. CHARLES BELLIS, Downton Hall Gardens, Ludlow, exhibited four *Cordylines*, named respectively *Charles Bellis*, *Ludloviensis*, *Salopian*, and *Downtoniana*, all the narrow-leaved section, some lighter, some darker coloured.

Col. HALFORD THOMPSON, Teignmouth, exhibited a *Palm* and a *Marguerite* in glass pots, to show how well the plants rooted in *Jadoo-fibre*.

Mr. ROBT. SYDENHAM, Tenby Street, Birmingham, exhibited a little wire-clip for securing *Carnations* or other flower-spikes to stakes in place of tying them with bast. Rounded stakes and a few other sundries were displayed also.

Mr. J. WATTS, Hamilton House, Newmarket (gr., Mr. J. Heath), exhibited thirty plants of a *Wallflower* named *Jno. Watts*, the foliage being variegated with yellow.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, showed a few hardy plants in flower, including *Primula obconica rosea*, *P. purpurea plena*, *P. sulphurea plena* (double white and double purple *Primroses*), and *P. denticulata*; also several *Saxifrages*, *Anemone Pulsatilla*, *Hepatica triloba*, *Valeriana Phu aurea*, *Androsace carnea*, and a fine lot of *Megacodon Stracheyi*.

Messrs. J. LAING & SONS, Forest Hill and Catford, exhibited a large miscellaneous table of plants in pots, chiefly stove

and intermediate-house subjects and plants forced into flower. Noticeable for variety or good culture, were *Lantana aurea*, the leaves of a yellowish-green colour, *Dracæna Sanderiana*, *D. Goldiana*, *Caladiums* in variety, the last named handsome decorative plants, with good leaf development for so early a part of the season. *Cliveia miniata* in named and unnamed varieties provided generally with fine corymbs; small furnishing examples of *Azalea mollis* and *Codæums*.

Their varieties of *Streptocarpus*, with large well-shaped blossoms of various shades of purple, also white with purple stripes in the throat, was likewise shown. The adjectival name *multiflora* was attached to this strain. Some plants of the somewhat rare *Leea amabilis* with capitally coloured leaves, were exhibited under a bell-glass. Other plants calling for remark, were *Richardia Elliottiana*, *Boronia elata* and *B. megastigma*, *Azalea dianthiflora* and *Rhopala species*. An award of a Silver Banksian Medal was made for the group.

Messrs. LAING made a display of florists arrangements which very prettily terminated on one of the central tables. A simple shower-bouquet of *Narcissus* blooms was very pretty, and a harp composed of choice Roses and other flowers, though formal in design would appeal to many tastes. Nice little button-holes were included also, and a well-flowered plant of *Cœlogyne cristata*.

Messrs. J. HILL & SON, The Nurseries, Lower Edmonton, exhibited a pretty bank of exotic Ferns, including the following notable species and varieties:—*Asplenium Colensoi*, *Gymnogramma Parsonsii*, a silver-farinose species of a neat dense habit; *Pteris nemoralis*, with semi-erect fronds, the younger ones of a reddish-green tint; *Davallia tenuifolia stricta*; *Pteris Victoriae*; *Nephrolepis davallifoloides furcata*, a distinct tufted variety; *N. cordata compacta*; *Lastrea erythrosora*, the young fronds of which are of a bronzy colour; *Blechnum brasiliense*, distinct-looking; *Pteris tremula Smithiana*, a frizzled and tasselled species, of dwarf habit, the fronds of a deep green colour. A basketful of *Adiantum* scutum showed up excellently the coppery tint of the young fronds; *Lastrea lepida*, as a lot of healthy young plants, a beautiful plant; and *Pteris arguta* formed a pretty object. The bank was backed with Ferns of large size in variety, so as to mask the wall. The exhibitor was awarded a Silver Banksian Medal.

Mr. H. B. MAY, Nurseries, Upper Edmonton, showed pretty examples of *Lomaria ciliata major*, 2½ feet in height of its crown of tough fronds, forming a very decorative object. The few small plants of the species surrounding the large plant were even prettier, the fronds differing much in appearance from those of the older plant.

Mr. MAY exhibited a group of eight varieties of *Clematis*, viz., *Fair Rosamond*, *Miss Bateman*, *Sir Garnet Wolseley*, *Lady Londesborough* and *Lord Londesborough*, *Miss Quilter*, and a few other well-known varieties.

Narcissus Committee.

Present: Messrs. J. T. Bennett-Poë (chairman), C. R. Scrase Dickens, J. de Graaff, Jas. Walker, A. Kingsmill, Miss Willmott, Rev. G. H. Engleheart, Rev. S. E. Bourne, and others.

The frosts and drought of March have considerably checked the growth of the *Narcissi*, which was unduly advanced in February, so that a large proportion of the flowers shown were from under glass. Two trade exhibits only were staged, by Messrs. BARR & SONS and T. S. WARE. The former was awarded a Silver Banksian Medal for a comprehensive group of well grown and finished flowers, consisting chiefly of trumpet varieties. Among these, the novelties *Weardale Perfection*, *Madame Plémp*, *Madame de Graaff*, and *Victoria*, were noticeable, the last-named especially being very fine (Silver Banksian Medal).

Mr. T. S. WARE received a Bronze Banksian Medal for a large bank of *Narcissi* in pots, flanked with alpine, &c. (Bronze Banksian Medal).

The Rev. G. H. ENGLEHEART showed several varieties of seedling white and pale trumpets; and Mr. JAS. WALKER, and Mrs. LAWRENSEN also sent seedlings.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the Chair; and Messrs. J. O'Brien (Hon. Sec.), De B. Crawshay, H. Ballantine, J. T. Gabriel, H. J. Chapman, F. J. Thorne, W. H. Young, W. H. White, T. W. Bond, G. W. Law-Schofield, E. Ashworth, W. H. Protheroe, S. Courtauld, H. M. Pollett, E. Hill, and N. C. Cookson.

The display of Orchids was not so extensive as usual at this part of the season, but there were some very remarkable exhibits staged, and as a whole it was very good. Especially noticeable was *Dendrobium nobile* *Ashworthianum* with pure white flowers, shown by E. ASHWORTH, Esq., of Harefield Hall, Wilmslow (gr., Mr. Holbrook). Notwithstanding the fact that *D. nobile* was introduced about sixty years ago, and importations have arrived from different localities, this is the first quite white form which has appeared at the meetings or shows of the Royal Horticultural Society. The flowers were of fine form and white, with the exception of a slight greenish-yellow tinge at the base of the lip (First-class Certificate). The exhibitor showed *Odontoglossum hybridum* *Ashworthianum*, which was thought to be cross between the rose-coloured *O. Cervantesii* *Haecinum* and *O. cordatum*. It has flowers similar in form to those of *O. aspersum*; the sepals yellowish, heavily barred with brown; the petals rose-coloured, with two or three red-brown marks at the base; and the lip coloured rose (Award of Merit).

Baron Sir H. SCHRODER, The Dell, Egham (gr., Mr. H.

Ballantyne), showed the beautiful *Odontoglossum crispum* "Princess Christian," a very large flower possessing a clear white ground handsomely blotched with irregular brown spots; the lip and crest, which were peculiar, suggested hybrid origin, as do many of the blotched *Odontoglossums* known as "crispum" (First-class Certificate).

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Aldous), showed again the fine *Odontoglossum* × *excellens*, *Rosslyn* var., for which a First-class Certificate was previously awarded. The flowers were better than when the plant was last shown. It is one of the best varieties of *O. excellens*. The flowers measured 3 inches across, of a thick and firm substance; of a clear yellow-ground colour, blotched with chestnut-brown. The limbs of the flower were nearly equal, and of about 1 inch in width (Cultural Commendation).

Mr. THOMAS ROCHFORD, Turnford Hall Nurseries, Broxbourne, showed as *Odontoglossum* × *Rochfordianum*, a very remarkable natural hybrid, with richly-spotted flowers of middle size, approaching closely in appearance to those of *O. crispum* *leopardinum*. The flowers were creamy-white, spotted with a rich shade of crimson. The fringed lip suggested *O. Hunnewellianum* as being one of the parents (Award of Merit). Mr. Rochford also showed *Dendrobium nobile* *albiflorum*, with flowers larger than usually obtain.

From MME. IDA BRANDT, Riesbach, Zurich (gr., Mr. Schlecht), came *Oncidium Phalaenopsis Brandtiae*, a very fine form of the plant often seen in gardens as *O. cucullatum* *Phalaenopsis*. The flowers were 2 inches in length, the lip being more than 1 inch wide where broadest. The sepals are white, heavily blotched with claret-purple; the lip is white, with a deep yellow-coloured crest, and bright purple markings at the base (Award of Merit).

MME. BRANDT also sent the singular-looking *Oncidium ansiferum*, and *Odontoglossum Hunnewellianum*.

Sir TREVOR LAWRENCE, Bart., Burford, Dorking (gr., Mr. W. H. White), showed three well-bloomed plants of the pretty *Epidendrum Endresii*, with white and violet flowers; the rare *Sarcochilus Hartmannii*, a finely-flowered specimen of *Masdevallia* × *Pourbaixii*, *M. Veitchiana grandiflora*; and the remarkable *Epidendrum varicosum*.

Messrs. HUGH LOW & CO., Clapton, were awarded a Silver Banksian Medal for a very effective group made up of remarkably fine specimens of *Cattleya Trianae*, *C. Mendeli*, *Dendrobium Boxalli*, and other *Dendrobiums*; the handsome *Cymbidium* × *eburneo-Lowianum* var. *marmoratum*, with large flowers of a cream-white hue marbled with rose; the rare *Phalaenopsis intermedia* *Portei*, varieties of *Odontoglossum crispum*, *O. triumphans*, *O. Andersonianum*, *O. mulus*, *Lelia cinnabarina*, &c.

J. T. GABRIEL, Esq., Palace Road, Streatham Hill (gr., Mr. E. Ranson), showed *Cattleya Trianae* *Gabriel's* var., with very large flowers, the sepals and petals of which were blush-white, the lip bearing a bright crimson blotch with light margin.

J. B. BROOKES, Esq., Finstall Park, Bromsgrove (gr., Mr. J. Drew), showed *Odontoglossum crispum* *roseum*, a flower of good form and substance. Dr. F. HILLS, The Elms, Campbell Road, Croydon, showed *Odontoglossum coronarium* *miniaturum*, Hills' variety.

Messrs. B. S. WILLIAMS & SON, Victoria and Paradise Nurseries, Upper Holloway, staged a good group, in which were several well-bloomed *Cœlogyne cristata* *alba*, *Calanthe Williamsii*, *Zygopetalum* × *Perrenoudii*, *Odontoglossum crispum* *roseum*, and *O. c. flavolum*, the handsome *Phaius* × *Norman*, *Cypripedium* × *Harrisianum* *superbum*, *C. × Io superbum*, *C. × Lathamianum*, &c. (Vote of Thanks).

Mrs. LAURA C. JOAD, Patching, Worthing (gr., Mr. Standing), showed *Cymbidium* × *eburneo-Lowianum*, and a very fine three-flowered inflorescence of *C. eburneo*.

Fruit Committee.

Present: Geo. Bunyard, Esq., in the chair; and Messrs. H. Balderson, T. F. Rivers, A. F. Barron, W. Bates, J. Cheal, A. Dean, Robt. Fyfe, W. Gleeson, C. Herrin, J. Laing, F. Q. Lane, G. Norman, W. Pope, W. Poupard, G. Reynolds, J. H. Veitch, H. W. Ward, Jesse Willard, J. Wright, and Geo. Wythes.

APPLE AND PEAR COMPETITION.

Apples, dessert.—Mr. Tallack, gr., Livermere Park, Bury St. Edmunds, was 1st with *Lamb Abbey Pearmain*, the fruits being a clear and nice-looking sample of this small-fruited variety; 2nd, Mr. C. Herrin, gr., Dropmore, with *Sturmer Pippin*. Other varieties shown were *White Nonpareil*, *Mannington Pearmain*, *Scarlet Nonpareil*, *Court Pendu Plat* and *Dutch Mignon*.

Pears, dessert.—A dish of *Ne Plus Meuris* was shown by Capt. CARSTAIRS, Welford Park, Berks (gr., Mr. C. Ross), obtaining a 2nd prize. Other varieties shown were *Bourré Bretonneau*, *Bergamotte d'Esperen*, and a variety without a name.

Mr. G. Wythes, gr. to EARL PERCY, Sion House, Brentford, showed six half-pound punnets of *Laxton's Royal Sovereign Strawberry*, receiving a Cultural Commendation.

Horticultural Soils.

The following is an extract of the lecture given by Mr. WILLIS "On Soils," on Tuesday, at the Drill Hall.

The Lecturer, in his opening remarks, said that the value of different soils for horticultural purposes is greatly dependent upon the original material from which they were made, and upon the state of fineness to which they have been reduced.

The soil must allow of the free percolation of both water and air, which are so necessary to the life and

growth of the plant, and to the due preparation of plant-food in the soil. It must retain sufficient moisture to furnish the growing crop with an immediate supply of water, and its pores must be sufficiently fine to allow of the ascent of water from the subsoil by capillary attraction. It must store up some of the heat received from the sun in the day time, and so render the temperatures of the soil more equable. It also serves as a protective covering to roots and seeds against excessive summer heat and winter frosts. A soil should contain in itself a stock of the mineral food necessary to the growth of crops, and it must constitute the laboratory of a number of wonderful actions whereby plant-food is always being prepared little by little for reception and assimilation into the plant.

Speaking of the soil as a source of plant-food, the lecturer said, where any plant, however lovely, has once grown and died away, its remains gradually decay and add a little vegetable or organic matter to the soil, rendering it thereby capable of growing a better plant the next season. As the soil becomes richer in carbonaceous and vegetable matters, higher organised plants will occupy it; these pass through the same phases of life as the plants of simpler structure, and enrich the soil at an increasing rate. It happens, therefore, that the virgin soils, as they are termed, derived from the heath, the forest, or the prairie, which are first ploughed up by the settlers in new countries, are richly charged with a blackish-brown vegetable substance, known under the general name of humus, and recognised as one of the marks of a fertile soil; in fact humus was considered by agricultural chemists in the early part of the present century to be the main source of soil fertility.

A soil rich in organic matter or humus, is rich in nitrogen; while a soil poor in organic substance is poor also in nitrogenous plant-food; and the permanent fertility of a soil is found to be very closely connected with its power of retaining plant-food. The composition of various soils was shown by means of diagrams, and the investigations pointed to the fact that the very rich peat-moulds, leaf-moulds, and turf-moulds, &c., which are so greatly valued for horticultural purposes, generally contain an excessive amount of fibrous-rooted material, or of leafy organic matter, with a correspondingly large amount of nitrogen. It is these constituents which by their abundance produce the greatest fertility.

A section was devoted to Jadoo fibre, which although not a soil, has been recommended to take the place of mould in certain gardening practises. It was shown to consist of peat moss, to which soot, bone meal, and gypsum, with a small quantity of phosphoric acid and potash, has been added; and the whole essence of the success of this material for plant-culture lies in the amalgamation of the various plant-food ingredients.

As soil fertility is of so much importance to the horticulturist in the productiveness of the garden, and as the final returns may be expected to be directly proportionate to the amount of nitrates which it contains, and to the facilities or favourable conditions offered for the conversion of organic nitrogen into ammonia and nitrates, the subject of nitrification in the soil becomes one of intense interest, and was dealt with pretty fully by the lecturer.

Recent investigations have shown that the nitrifying microbes are in greater or less number in all fertile soils, but are most active in soils under cultivation, teaching the advantage of the frequent use of the hand-hoe and other implements of tillage in the open garden, and of a friable porous soil for potting purposes. The nitrification of a cultivated soil which takes place in the spring is, as a rule, quite insufficient to meet the food requirements of early-sown spring vegetables, hence the advisability of using some stimulating manure, such as nitrate of soda, guano, sulphate ammonia, or soot, if rapid production is required.

The next question considered was that of available plant-food. A large part of the elements of plant-food contained in soils is present in such a condition that plants are unable to make use of it. It is not the total proportion of phosphoric acid, or of potash, or of nitrogen, that rules a soil's fertility for horticultural purposes, but the amount of each of them that is present in an immediately available condition.

How plants are dependent upon the food supply in the soil was shown by the fact that one horticultural soil may have a proper texture, with a suitable amount of moisture, and in fact a full supply of everything the plant needs except phosphoric acid. If so, it cannot yield a full crop. Add phosphate in an available form, and the growing plants will be benefited. Another soil may be deficient in potash, another in lime, another in nitrogen; still another in two or three of these substances.

This same variation may run through inherent fertility of the soil, and in the solubility of its constituents. Therefore, a horticultural soil may be deficient in available mineral ingredients, or in available nitrogen. Or it may be so compact, that air and moisture cannot get into it to work over the crude material it contains, nor the plant roots make their way through to obtain the food that has been made soluble. Again, it may be so loose and non-retentive, that the food constituents will escape by drainage. Or, on the other hand, it may be so dry that fertilisers will be useless, and plants wither for lack of moisture, or so wet and cold as to prevent plant-growth. In these several cases, proper tillage operations were recommended to assist in amending the soil texture, so that its power of holding water might be improved, and its supply of available plant-food increased. Then by a suitable manurial treatment it may be brought into condition to yield bountiful returns for all that is done to it.

In conclusion, a few practical remarks were made upon the

three main constituents of plant-food in horticultural soils, namely, nitrogen, potash and phosphoric acid.

With regard to nitrogen, it was shown that, although the nitrification in rich garden soils, leaf-moulds, and peat-moulds may be sufficiently active for the gardener to dispense with artificial nitrogenous manures in most cases, yet there are certain species of plants which rapidly develop a large mass of foliage, and these cause a rapid and extensive demand upon the available nitrogen of the soil. For such plants it will always be advisable to use nitrate of soda, sulphate ammonia, guano, soot, or similar materials as manure.

Phosphoric acid occurs in very small actual assimilable quantities in most soils, however rich. It is, therefore, necessary to add this ingredient by a manurial application if full crops are to be obtained. The best form in which this substance may be added to horticultural soils, is by bone phosphate, bone meal, or basic slag. Superphosphate of lime yields a certain proportion of phosphoric acid soluble in water. But in rich moulds cheap mineral superphosphates are not recommended, as the introduction of free sulphuric acid into soils poor in lime would be hurtful to plants.

Potash is a constituent in all rich horticultural soils; this becomes only slowly available for vegetation. For certain cultures, more especially that of Ferns, Palms, Vines, Potatoes, Roses, &c., potash manures have a very beneficial effect when applied to leaf-mould composts. The most rational mode of application is to use carbonate of potash, one of the chief ingredients in wood ashes, or kainit. This salt is retained by the soil, and plants are able to absorb it as they need. The proportions to be used must vary, according to the requirements of the plants cultivated.

NATIONAL CHRYSANTHEMUM.

ADJOURNED ANNUAL MEETING.

MARCH 22.—The adjourned annual general meeting of the members of this Society took place on Monday evening last at Anderton's Hotel, Fleet Street, E.C. There was a large attendance of members, and in point of duration, as in some other respects, the meeting may be described as an extraordinary one. It was called for six in the evening, and the chair was taken by Mr. T. W. SANDERS about fifteen minutes later, but it was twenty minutes past eleven before the meeting separated. As a committee meeting had been held from five to six o'clock, the chairman and a few others had sat uninterruptedly for upwards of six hours.

When the Secretary had read the revised balance-sheet (showing that outstanding accounts had been paid by the withdrawal of £50 from the reserve fund), its adoption was formally moved from the chair, and duly seconded by Mr. B. Beckett. A rather long discussion was then commenced by Mr. Cholmeley, who pointed out a slight error which had been made (but which was subsequently explained satisfactorily), and asked why there were not the signatures of the auditors upon the revised sheet.

Mr. Pearce referred to the sum of £12 9s. 8d. for bill posting as appearing in both receipts and expenditure. When the questioner had been satisfied on this point, the Chairman read a letter he had received from the auditors, in which they declined to have anything to do with the revised balance-sheet. This was followed by a statement from Mr. H. J. Cutbush, one of the auditors, who said that the accounts as first presented were thoroughly examined, and the vouchers inspected; and Mr. Stubbs also said that the first report was an intelligible one, and it would be unwise and incorrect on their part to go further.

The Secretary then made a statement to the effect that the Society had always had to carry over a large sum of money from year to year, and since he had been Secretary he had honestly tried to reduce the amount. Mr. Dean then traversed a statement made by Mr. Gordon at the last meeting respecting the show expenses having greatly increased, declaring that such was not correct, but that the expenses were tabulated differently in the financial statement than they were formerly.

Mr. Moorman severely criticised the Society's financial policy at length, and declared that the printing was expensive and the purchase of medals also. The practice of letting the floor space in the Aquarium to vendors of "Sticks and Manures," and the consequent banishment of the Chrysanthemum blooms to the galleries, was a strong point in Mr. Moorman's criticism.

Mr. Spicer asked if the amended accounts had been sent out with the Treasurer's assent? Mr. Starling, Treasurer, replied that for years he did not know that there were unpaid accounts carried from year to year. When the Secretary informed him that such was the case, he refused any longer to affirm that the balance-sheet was a true one. Before resigning, he had determined, in the interests of the Society and of his successor, to acquaint every member with the present system by which the accounts were practically under the control of the Secretary alone. They had been obliged to take about £50 from the reserve fund to pay outstanding accounts, but instead of this the Society ought to obtain and preserve a reserve fund of at least £300 to £400.

Several questions were then put with a view to obtaining from the treasurer or auditors, an assurance that the revised balance-sheet was correct, and more than one member rebuked the auditors for failure of duty, it being affirmed that when they signed the first statement it was in their knowledge that debts were still outstanding. "Who is responsible for the revised balance-sheet," said one member. "Nobody has signed it, no one attaches importance to it, no

one owns it. Who is its father?" At length the treasurer accepted the responsibility, and said that Mr. Dean told him that up to the date the accounts were closed there was not one penny now owing, and he believed Mr. Dean.

Mr. H. Cannell remarked that they had paid the debts, they had clean hands, but a reserve fund reduced by one-half. They had been too lavish; it was now for the meeting to accept the position, and make up their minds for business in the future.

The balance-sheet was adopted almost unanimously. On the consideration of the report, Mr. Moorman proposed that it be held over until the meeting had heard the estimates of receipts and expenditure for 1898. The Secretary then read an estimate that had been made, which showed a balance against receipts of £48 10s. 8d., but the committee's alterations to same had resulted in an estimated balance in favour of receipts of £22 8s. The revised estimate was accepted.

Resuming the consideration of the committee's report, Mr. Moorman proposed that in the first paragraph the words, "its resources are as great as ever, its supporters more numerous, it is financially sound, and its prestige knows no diminution," should be deleted; but eventually the motion was lost on the ground that it might be accepted as the opinion of the committee. The motion from the chair that the report, with the exception of certain modifications proposed by the committee, be received, printed, and circulated, was passed. Votes of thanks to the auditors, president, and others having been passed, the meeting turned its attention to the election of officers. The president (Sir ERWIN SAUNDERS) was re-elected with acclamation.

The resignation of the treasurer having been received, it was decided to confer the honorary fellowship of the Society upon Mr. Starling, and to ask his acceptance of the Society's small Gold Medal, and a letter inscribed upon vellum testifying to the fidelity with which he had worked for the Society for upwards of twenty years, and further that it was the result of his labour, extending over some years, that the first reserve fund was formed. Mr. Starling suitably replied, and declared that his one desire was that his successor might be what he himself had never been, "a treasurer in effect as well as in name."

Messrs. R. Ballantyne and Geo. Gordon were then nominated for the vacant office, and this, and all cases where there were more than one member proposed for an office, was decided later in the evening by ballot. After vainly trying to escape the position of chairman of committee, the present chairman (Mr. T. W. Sanders) was prevailed upon by an unanimous meeting to continue in the office for another year, but he accepted it on the perfect understanding that he would not be held responsible for the policy of that committee; his work would be to see that the business was properly and orderly conducted, but he would not take "sides" on any question. Mr. P. Waterer was re-elected vice-chairman.

The appointment of secretary being the next business, Mr. Moorman proposed and Mr. Rundle seconded that hereafter the Secretary be a paid officer, without a vote upon the committee, which was carried.

Mr. H. Cannell then proposed, and it was seconded, that Mr. R. Dean be elected to the office; and Mr. Moorman proposed, and Mr. Mold seconded, the name of Mr. G. W. Cummins, both of which names went to the ballot. For the post of Foreign Secretary, Mr. Harman Payne was re-elected unanimously. Nominations were then made for members of committee, in the place of those retiring. The result of the ballot was declared as follows:—Treasurer, Mr. R. Ballantyne. General Secretary, Mr. R. Dean, 63 votes; Mr. Cummins, 43 votes; Mr. Dean was therefore declared duly elected. As members of Committee, Messrs. T. Bevan, G. Langdon, A. Taylor, W. Howe, W. Wells, J. P. Kendall, W. Higgs, T. L. Turk, J. T. Simpson, F. Gilks, Robt. Fyfe, W. Daniels, and A. Outram. Messrs. Wells, Fyfe, and Outram are new members. The auditors for the coming year will be Messrs. A. E. Stubbs and J. Cholmeley.

The meeting considered the revised rules of the society, and passed various amendments to same. Rule III. was modified to the effect that delegates of affiliated societies may vote at committee meetings, and that the general secretary may not do so. Under Rule IV., notice of nominations to offices will be unnecessary. Rule VII. will now declare that a member's subscription will become due on the 1st day of January each year. Rule X. further defines that delegates of affiliated societies may vote at committee meetings. Rule XI. will now fix the annual general meeting for the first Monday in February of each year. Rule XII. was modified in the direction of transferring the business of superintending the show from the secretary to the committee. Under Rule XVII. it has been decided to close the accounts at the end of the calendar year, and that printed copies of same be distributed to the members seven days before the annual meeting. Rule XIX. was altered, so that notice of proposed alterations to rules must be made fourteen days before the annual meeting instead of before January 31, as formerly.

On the motion of Mr. Moorman, it was agreed that the following recommendation be sent, as an instruction to the committee:—

"That a sub-committee of five members (exclusive of *ex officio* members) be appointed to enquire—

(a) What places can be obtained for holding our future exhibitions, either by a subsidy as now, or in reliance on our own resources to proceed on independent lines.

(b) To closely examine the whole question of minor shows with the object of ascertaining their advantages or otherwise to the Society.

(c) To fully consider the question of selling the floor space, and to report the result of their investigations to the general committee, who shall formulate such recommendations to a general meeting of members to be held on the first day of the November Exhibition, and that no future fixtures be made before this date."

Mr. E. Calvat was elected an honorary Fellow of the Society.

WARE AND DISTRICT HORTICULTURAL.

MARCH 15.—Mr. Fulford, gr. to R. Walters, Esq., presided at the fortnightly meeting of this Society on the above date, when Mr. Challen, nurseryman, Stanstead, gave a very interesting account on the construction of the "Hot-water Apparatus," wherein he described a system of heating adopted by him, minimising the cost of fixing boilers, and placing the pipes so as to insure efficient circulation in gardens adjacent to streams, and subject to be flooded, and where the stokehole is frequently submerged.

Mr. Challen having occasion to fix a boiler in a place where it would be altogether impossible to get a dry stokehole by sinking the boiler some distance below the level of the ground unless he went to the expense of having the sides and bottom cemented so as to make the hole water-tight, and even then he was rather doubtful of keeping out the water, as the cement would be liable to crack from the action of the heat under the boiler, he determined to fix his boiler on the ground level (the ash-pit only being dug out), he then connected the flow-pipe to the top of the boiler, but instead of taking the pipes on the rise to the extreme end of the houses, he fixed them so as there would be a gradual fall, graduating it right round the houses and back to the boiler, connecting the return pipe to the boiler in the ordinary place. He had used that boiler for two winters, and found it answered very well, the heat being distributed evenly over the houses. After some discussion, a vote of thanks to the lecturer and chairman terminated the meeting. A. W.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 10.—Meeting at the Manchester Coal Exchange on the above date. Present: Messrs. G. Shorland Ball (in the chair), G. W. Law-Schofield, Rappart, Greenwood, Sidebotham, Warburton, Cypher, Gratrix, Johnson, Weathers, and Gent (Hon. Sec).

G. SHORLAND BALL, Esq., Ashford, Wilmslow (gr., Mr. Hay), showed a very fine form of *Cattleya speciosissima* Ernesti (First-class Certificate), *Dendrobium Paxtoni*, very closely allied to *fimbriatum*, and two forms of *D. Schneiderianum*.

D. B. RAPPART, Esq., Liscard, Cheshire (gr., Mr. Nicholson), staged the very pretty and rare *Dendrobium Luna* (Award of Merit).

G. W. LAW-SCHOFIELD, Esq., New Hall Hey, Rawtenstall, exhibited the beautiful *Dendrobium Rainbow* (First-class Certificate), *D. Schneiderianum* (Award of Merit), *D. Luna* (Award of Merit), *D. Kenneth*, and *Cypripedium Schofieldianum* (Award of Merit).

THOMAS STATTER, Esq., Stand Hall, Whitefield (gr., Mr. Johnson), showed *Dendrobium splendissimum* illustre, which we think was good enough to have received a First-class Certificate. It is undoubtedly the best of its section; it obtained an Award of Merit only. The same exhibitor also showed *D. splendissima*, *D. Juno*, *Cypripedium Rubens*, a very fine cross between *bellatulum* and *callosum* (Award of Merit), a very dark form of *C. hirsutissimum*, and *Laelia Euterpe*.

H. GREENWOOD, Esq., Highfield, Haslingden (gr., Mr. Spurr), showed *Cattleya Trianaei*, Highfield variety (Award of Merit), *C. Walkeriana*, *Cypripedium conco-callosum*, and *Cymbidium eburneum*.

S. GRATRIX, Esq., West Point, Whalley Range (gr., Mr. McLeod), staged *Odontoglossum Wilckeanum*, with a magnificent spike (Cultural Certificate), *Cypripedium Laysenianum* (Award of Merit), *C. Mary Gratrix*, *C. Thompsoni* (Award of Merit), *C. Harrisianum albens* (Award of Merit), *Dendrobium Rubens grandiflora* (Award of Merit), and *Dendrobium crassinode album* (Award of Merit).

E. J. SIDEBOTHAM, Esq., Erlesdene, Bowdon (gr., Mr. Glover), showed *Dendrobium nobile* Ballianum, very well flowered (Award of Merit), *D. Desdemona*, and *D. Schneiderianum*.

A. WARBURTON, Esq., Vine House, Haslingden, staged an interesting collection of twenty four varieties of *Dendrobium* blooms, which received a Vote of Thanks.

O. O. WRIGLEY, Esq., Bridge Hall, Bury, staged *Cypripedium oenanthum superbum*, *C. Mastersianum*, and *C. Leeanaum* × *Boxalli*.

H. H. BOLTON, Esq., Height Side, Newchurch, showed *Mitonia Endressii*, a beautiful Orchid, very rarely seen.

MESSRS. LINDEN & Co., Brussels, staged *Odontoglossum Ruckerianum superbum*. This was a magnificent variety, and very well flowered, and although it received only an Award of Merit was, in our opinion, good enough for higher honours.

W. DUCKWORTH, Esq., Shawe Hall, Flixton (gr., Mr. Tindale), showed *Dendrobium nobile*, Duckworth's variety (Award of Merit), *D. Leechianum*, and *Cattleya Trianaei Dorothy*.

E. STANLEY CLARK, Esq., Oak Alyn, Wrexham (gr., Mr. Edwards), showed *Cattleya Trianaei*, Mrs. Stanley Clark

(Award of Merit), C. T. Denny, *Odontoglossum crispum*, Mrs. Stanley Clark (Award of Merit), O. Harrynum, *Cypripedium Jathmanianum* (Cultural Certificate), and *Dendrobium nobile*.

MESSRS. CHARLES WORTH & Co., Bradford, showed four very pretty *Phaius* seedlings—*Cooksoni*, Norman, Norman aurea (Award of Merit), and N. rosea (Award of Merit).

MR. CYPHER, Cheltenham, staged a beautiful group of *Dendrobiums*, in the pink of health and condition, viz., *nobile splendens* (Cultural Certificate), N. magnifica (Cultural Certificate), N. Fisheri (Award of Merit), and N. majus (Award of Merit).

MESSRS. SANDER & Co., St. Albans, showed a very fine plant and good variety of *Lycaste Skinneri alba* (Award of Merit), and a *Cypripedium* seedling, *Harrisianum superbum* × *Boxalli atratum*.

MR. WM. OWEN, Hartford Nurseries, Northwich, showed *Cattleya Trianaei* Hartfordensis.

H. SHAW, Esq., Heath Field, Birch Vale (gr., Mr. Cliffe), showed *Cattleya Trianaei*, and *Dendrobium nobile nobilium*.

MR. C. J. CROSFIELD (no address given) showed a very pretty *Cattleya Trianaei albens* (Award of Merit).

W. H. ALMOND, Esq., Alumscar, Blackburn, showed *Odontoglossum crispum Dorothy*, a very fine spotted variety, of good form (Award of Merit).

SPRING FLOWERS AT BIRMINGHAM.

MARCH 16, 17.—The subscribers to the Edgbaston Botanic Gardens, saw on the above dates, arranged in the conservatories of those gardens, a very early and lovely show of forced spring flowers.

The Society had held several in the past, but for want of funds they had to be dropped. Last year Mr. R. Sydenham generously furnished the needful prizes, and has again done so this year in the hope that it may soon be possible to resuscitate the spring show for the Society; the recent result was to more than double the exhibits, and a brilliant display was furnished. The whole was effectively arranged by Mr. W. B. Latham, the Curator, and there was a crowded attendance each day.

The schedule commenced with single *Hyacinths* in dozens and half-dozens. Mr. W. A. PARSONS, Moseley, and Mr. M. C. CARTWRIGHT, Selly Oak, being in the large class 1st and 2nd, but there were five prizes in each and all the classes. Single *Tulips* made a brilliant bank, these too being shown in twelves and sixes, in pots not exceeding 8 inches wide. The best twelve came from Mr. A. Cryer, gr. to J. A. KENRICK, Esq., Barrow Court, a very fine lot, who was close run by Messrs. J. ISAAC COOKE, of Shrewsbury. Mr. E. W. SHARP, of Edgbaston, had the best six pots. Single *Daffodils* also brought numerous collections, Mr. KENRICK having the best dozen finely-grown and flowered. In the class for six pots, Mr. J. SCEANEY, Harborne, was 1st. Judging by the numbers of half-dozens shown, *Polyanthus Narcissi* seem to be very popular forced flowers in the Midlands. The finest of these came from Mr. H. W. HULSE, Beech Lane. Mr. KENRICK had the best six pots of *Lily-of-the-Valley*, finely flowered, and was also 1st for six *Spiræas*, three of *astilboides*, and three of *japonica*; and again with six superb *Cinerarias*, chiefly blues.

MR. ISAAC COOKE had the best collection of cut *Narcissi*, a large and very varied one. Messrs. KENRICK, HULSE, and ISAAC COOKE took the prizes in this order for very beautiful collections of flowering and foliage plants. Messrs. PERKINS & SONS, of Coventry, staged singularly beautiful *Orchids*, *Rose* and *Daffodil* bouquets, with other fine exhibits. Mr. SYDENHAM put up from his private garden a big bank of *Hyacinths*, *Tulips*, *Daffodils*, and other flowers including *Cyclamens*. Amongst *Tulips*, a white *Pottebaker*, having golden base, was unique. The Lady MAYORESS OF BIRMINGHAM sent a *Hyacinth*, *Grand Maitre*, carrying eleven well-developed spikes.

READING AND DISTRICT GARDENERS'.

MARCH 21.—"Common Mistakes in Fruit Culture" was the subject of an instructive lecture given by Mr. G. BUNYARD, of Maidstone, before the Reading and District Gardeners' Mutual Improvement Association, on the above date, in the Club Room, "British Workman." Mr. C. B. STEVENS presided over a large attendance of members, including a contingent from the Wargrave Gardeners' Association.

A feature of the meeting was a fine exhibit of *Orchids* by Mr. Woolford, gr. to A. PALMER, Esq., of East Thorpe, including some splendid forms of *Dendrobium nobile* and *D. Wardianum*, two pieces of the latter in 4-inch pans carrying eighty and seventy-eight blooms.

NATIONAL DAHLIA SOCIETY.—A meeting of the committee to make arrangements for the exhibition in September next took place at the Horticultural Club on the 22nd inst., the president, T. W. GIRDLESTONE, Esq., in the chair. The judges were appointed in the several classes, and the following special prizes were announced: by F. A. Fellowes, Esq., a silver-cup for the best bloom in the exhibition, show or fancy; by Mr. Thomas Hobbs, for the best show Dahlia, and also for the best fancy Dahlia, shown by amateurs; by Mr. A. Dean, for the best

bunch of six blooms of any white Cactus Dahlia; and by Mr. R. Dean, for the best bunch of any new Cactus Dahlia exhibited for the first time. The president announced that he was at work on the preparation of a catalogue of Dahlias, and was arranging the various sections on much the same lines as the catalogue of the National Chrysanthemum Society.

MARKETS.

COVENT GARDEN, MARCH 24.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

<i>Mint</i> , per dozen	6 0-9 0		

Broccoli.—The Italian consignments are not in such good condition as hitherto. *Brussels Sprouts* are few. The supply of *Cucumbers* is moderate. *Horseradish*, loose, from Cheshire, is something new. *Onions* keep firm in price, and will probably remain so until consignments arrive from Egypt. *Rhubarb* from Yorkshire is not quite so large a trade as last week, and prices easier. *Seakale* is rather cheaper. *Turnips* (green round) appear for the time wonderfully good.

POTATOS.

We have had larger arrivals from the Continent during the past week, but owing to cold weather prices have been supported. *Maincrops* and *Saxons*, 105s. to 120s.; *Magnums* and *Bruce*, 100s. to 120s.; *Blacklands*, 100s. to 110s.; *Dunbar Maincrops*, 125s. to 180s. per ton. Foreign Ware, 4s. to 6s. per bag. New Potatoes, 11s. to 20s. per cwt. John Bath, 82 and 84, Wellington Street, Covent Garden, W.C.

OUT FLOWERS.—AVERAGE WHOLESALE PRICES.

Cob-nuts, p. 100 lb.	16 0-18 0	Strawberries, p. lb.	10 0-12 0

Some home-grown Apples quoted have kept remarkably well. Cobnuts are a dull trade, and there is little demand. Grapes, Capes boxes come to hand in bad condition. Jersey new are beginning to arrive.

SEEDS.

LONDON: March 23. — Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., report to-day's market thinly attended with, for the time of the year, a comparatively small business passing. Some warm rains are now much wanted to bring on the sowing demands. As regards Grass and Clover-seeds, buyers are at present able to fill the wants for a small outlay. Alsike is scarce and dearer. For Tares there is a fair inquiry, whilst Rye continues in good request. Scarlet Runners are advancing in price, but Canadian Runner Beans continue very cheap. Mustard, Rape, and Linseed are firm. The sale for Peas, Haricots, and Lentils is slow. There is no change this week in Bird-seeds.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending March 19, and for the corresponding period of 1897, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1897.	1898.	Difference.
	s. d.	s. d.	s. d.
Wheat	27 11	35 6	+ 7 7
Barley	22 8	28 0	+ 5 4
Oats	16 2	17 10	+ 1 8

FRUIT AND VEGETABLES.

GLASGOW: March 23.—The following are the averages of the prices at this market during the past week:—Apples, 4d. to 8d. per lb.; Grapes, home, 2s. to 3s. do.; do., foreign, 4d. to 6d. do.; Cabbages, Spring, 6d. to 8d. per doz.; Parsnips, 4s. to 4s. 6d. per cwt.; Herbs, 1d. to 2d. per bunch; Leeks, 1s. 6d. to 3s. per dozen bunches; Mint, green, 9d. to 10d. per bunch; Onions, Dutch, 6s. per bag; do., Portugal, 9s. per case; Parsley, 1s. per stone; Potatoes, best, 10d. per stone; Carrots, 2s. 6d. to 3s. per bag; Artichokes, 3s. to 3s. 6d. per sieve; Cucumbers, 1s. to 1s. 2d. each; Lettuce, round, 1s. 3d. per doz.; Radishes, 1s. do.; Horseradish, 1s. 6d. to 2s. 6d. bundle; Mushrooms, 1s. to 1s. 2d. per lb.; Beetroot, 6d. to 7d. per doz.; Brussels Sprouts, 1s. to 1s. 3d. per stone; Spinach, 3s. to 3s. 6d. do.; Rhubarb, 10s. to 12s. per cwt.; Turnips, Swedes, 1s. to 1s. 3d. per bag; do., white, 1s. per large bunch; Celery, Scotch, 9d. to 1s. 6d. per bunch; do., English, 1s. to 2s. do.; Cabbages, Red, 1s. 6d. to 2s. 6d. per dozen; Savoys, 1s. to 1s. 6d. do.; Broccoli, 2s. 6d. to 3s. do.; Greens, 5s. to 6s. per 10 dozen.

LIVERPOOL: March 23.—Average of the prices at undernoted markets:—St. John's: Potatoes, 1s. 2d. to 1s. 4d. per peck; Cucumbers, 6d. to 8d. each; Grapes, English, 3s. to 4s. per lb.; do., foreign, 8d. to 1s. do.; Pine-apples, English, 4s. to 6s. each; Mushrooms, 1s. 6d. per lb. Birkenhead: Potatoes, 1s. 2d. per peck; do., new, 2d. to 6d. per lb.; Cucumbers, 6d. to 8d. each; Grapes, English, 2s. 6d. to 4s. 6d. lb.; do., foreign, 8d. do.; Pine-apples, English, 5s. to 7s. 6d. each; do., foreign, 3s. 6d. to 5s. 6d. do.; Mushrooms, 1s. to 1s. 6d. per lb. North Hay: Potatoes, per cwt.; Giants, 4s. to 4s. 4d.;

Main Crop, 4s. 10d. to 5s. 9d.; Bruce, 4s. 4d. to 4s. 10d.; Turnips, 6d. to 8d. per doz. bunches; Swedes, 1s. to 1s. 3d. per cwt.; Carrots, 2s. 3d. to 2s. 9d. do.; Onions, foreign, 11s. to 14s. do.; Parsley, 4d. to 6d. per dozen bunches; Cucumbers, 3s. to 4s. per dozen; Cauliflowers, 1s. 3d. to 2s. 6d. do.; Cabbages, 4d. to 8d. do.

CATALOGUES RECEIVED.

THE SURREY SEED COMPANY, Redhill—Farm Seeds.

WM. CLIBBON & SON, 10 and 12, Market Street, Manchester—Farm Seeds.

ISAAC HOUSE & SON, Westbury-on-Trym—Hardy Flowers and New Giant Violets.

MAURICE PRICHARD, Riverslea Nursery, Purewell, Christchurch, Hants—Alpine and Herbaceous Plants.

THOMAS KENNEDY & CO., High Street, Dumfries—Florists' Flowers, Herbaceous Plants, Roses, Stove and Greenhouse Plants, &c.

BARR & SONS, 12 and 13, King Street, Covent Garden, London—Hardy Perennial and Alpine Plants.

HARRISON & SONS, Leicester—Agricultural Seeds.

WALTER SIEHE, Mersina, Turkey in Asia—Re-introductions in Plants and Seeds from Cilicia and Cappadocia.

GARDENING APPOINTMENTS.

MR. J. W. DISTANCE, Foreman at Matten Hall Gardens, Corbridge-on-Tyne, as Gardener to Major-General DUNCOMBE, Kilnwick Percy, Pocklington, Yorkshire.

MR. FRANCIS GORDON, for the last five years Foreman at Moncrieffe House, Bridge-of-Earn, as Gardener to Sir ALLAN MACKENZIE, Bart., of Glenmuick, Ballater, N.B.

MR. WILLIAM POOLE, until recently Head Gardener at Cottes-hall Manor, Godalming, as Head Gardener to the Right Hon. Sir ALGERNON WEST, K.C.B., Wanborough Manor, Guildford, Surrey.

MR. WALTER ALLSOP, for some years Foreman under his father at Dalton Hall, Hull, as Head Gardener to the Right Hon. J. F. S. FOLJAMBE, Osberton, Worksop, Notts.

MR. JOHN WEATHERALL, lately Foreman, Cowdenknowes, Earliston, Berwickshire, N.B., as Gardener to Miss HOPE, Donavoud, Crieff, Perthshire.

MR. FREDERICK JOYNER, late Gardener to the Earl of DUDLEY, as Head Gardener to Captain the Hon. HERBERT ALSOPP, Walton Bury, near Stafford.

BOOKS: *Ino. Kneller*. There is no new book in print, but you might be able to pick up one at the second-hand book-stalls.

"CACTUS JOURNAL," &c. *Cereus*. Direct your enquiry to the publishers of the Journal, Messrs. W. H. & L. Collingridge, 148 & 149, Aldersgate Street, London.

CEYLON: *Trinco*. Both the P. & O. and the Orient Line; the former weekly, and the latter fortnightly. The Orient Line would probably be the cheaper, and the fare about 15 guineas. To obtain an idea of the climate of Ceylon, you could hardly do better than obtain *Hints on Gardening in India*, by G. Marshall Woodrow, printed at the Education Society's Press, Byculla, Bombay; and probably obtainable through Ed. Arnold, Publisher, Southampton Street, London, W.C. No variety of the Potato (*Solanum tuberosum*) would succeed in the tropical climate of Ceylon.

DISEASED LEAVES: *Constant Reader*. The leaves of Portugal Laurel are infested with a fungus giving off spores. The other Laurel leaves sent do not, however, show the same fungus. If only the shrubs of a single area are sickly in this way, it probably indicates something wrong with the soil, defective drainage, "pan," or some such cause affecting the roots. This would weaken the shrubs and render them liable both to fungus attack and discoloration.

DENDROBIUM WARDIANUM: *Veritas*. The basketing or potting should be done immediately after flowering; but surfacing with fresh sphagnum, and disturbing them as little as possible, is your best course, now that the young pseudo-bulbs have grown a foot in length. The plants do best and look the most graceful when grown in wooden baskets, and if a plant be in need of much more space, put the whole basket, plant and all, into a new basket, packing it round with small potsherds and sphagnum-moss, not so much as will exclude air or keep the moss too wet, but lightly, yet firmly.

GARDENERS' BENEVOLENT: *Another Subscriber*. Your letter was received with many others, but we did not consider under the circumstances that it was

necessary or desirable to go into personal details. All the candidates are worthy, or the committee would not have sanctioned the publication of their names.

MANURE: *F. F., Steaford*. We do not undertake to analyse manures or soils, as this work would entail more time than we could afford to give. If, however, you are a Fellow of the Royal Horticultural Society, you may have either one or the other analysed by an expert at a cost of less than the usual fee. Address the Secretary, 117, Victoria Street, Westminster, S.W.

MILDEW ON VINES: *J. H. S.* Use half an ounce of sulphide of potassium in 1 gallon of water, and apply with the syringe. More than one application may be necessary.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*Wilts.* 1, *Gesnera macrantha*; 2, *Begonia Ingrami*; 3, *Casuarina equisetifolia*; 4, *Pholidota* or species of *Cœlogyne*, not recognisable from specimen sent; 5, *Maxillaria* species; 6, *Cœlogyne fimbriata*.—*C. P.* 1, *Cupressus Goveniana*; 2, *Pinus parviflora*; many thanks.—*M. J., Newbury*. 1, *Winter Savory*; 2, *Asclepias curassavica*; 3, *Forsythia viridissima*; 4, *Thuja orientalis aurea*; 5, *Buddleia globosa*; 6, *Cupressus Lawsoniana*; 7, *Pinus* species, but which is not possible to determine without a shoot with cone; 8, send perfect specimen with flowers.—*S. G., Warwick*. The little round cones are the female and the others the male of *Cryptomeria japonica*.—*J. W.* *Coronilla Emerus*. *H. M. E.* *Erica carnea*.—*W. J. Taylor*. *Fritillaria meleagris*.—*G. S. K.* 1, *Adiantum hispidulum*; 2, *Adiantum cuneatum grandiceps*; 3, *Oxalis Ortigiana*.

PEAR TREE, I.: *T. H.* The swellings you send are what the French call *bourses*. Before flowers, and still more, fruit can be formed, nutritive matter must be stored up within easy reach. This consists of substances, such as chlorophyll, water, starch, sugar, proteids, substances which can be utilised as food, or which, if not themselves nutritive, can be rendered so by the agency of a ferment or other cause. The food must be within easy reach of the growing points, and easily conveyed to them. The swellings, then, are due to the accumulation of nutritive matter as a preparation for the growth of the fruit. In your specimens the preparations are rendered useless, owing to the death of the young wood or conducting tissue. What has killed it we do not know; presumably it was frost. The outer cortex is still alive, and apparently full of nutritive matter, so that the wood-buds, which are attached to it, have a fair chance of development. If you cut the swelling, either across or lengthwise, you will see the brown wood.

ROOTS II.: *T. H.* It is true, as you say, that roots are formed in particular localities. As to the reason why, we can only say that the conditions favourable to the development of roots must be in existence, and that roots are formed in consequence. The conditions are, a sufficient amount of moisture and heat, and a reserve of nutritious matter in the bulb-scale, leaf, or whatever it may be.

WOODCUTS: *E. E. B.* We have no figures of the plants named.

COMMUNICATIONS RECEIVED.—Nova Scotia School of Horticulture.—W. G. S., Leeds.—H. R.—G. C. H.—H. Werdmueller, publication unavoidably delayed.—Douglas, Junior, Buenos Ayres.—W. J. B.—T. CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper, MORE THAN DOUBLED, and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Weather, see p. xiv.)

THE Gardeners' Chronicle.

SATURDAY, APRIL 2, 1898.

THE HOME OF CARYOTA URENS.

THERE is, generally speaking, to the youthful mind a certain glamour surrounding the term Palm, primarily produced perhaps by the frequent mention of the name in holy writ, and the representations of the tree in books and pamphlets written for the young. As a child, the first book I had the patience to read from cover to cover was *Paul and Virginia*, and it was only very recently that I stumbled across a copy of the same book, and read it again with interest. The first reading gave birth to the longing to visit the tropics. This desire grew till I reached the state of manhood, when it was somewhat suddenly gratified, and I set sail in the year 1862 for India.

In those days Palms were not to be seen on "coster's" barrows, otherwise the desire to visit foreign climes for the sake of seeing their Palm-groves might have been somewhat damped. I had visited the Palm-house in the Edinburgh Botanical Gardens, and before embarking at Southampton I paid a hurried visit to Kew. What I saw at these two places only whetted my desire to pursue my journey to the East.

Arrived at Malta, I had the satisfaction of seeing Palms growing, not under glass, but under the sunny sky. Alexandria came next, with its cloud of windmills and clusters of Date-palms. Then the journey from thence to Cairo revealed a country mostly under water, with the stems of the Date-palms in the numerous groves standing in the flood, and gratefully taking up the revivifying waters of the Nile, their plumes tossing and waving as if in delight. Bombay, with its limited number of cultivated Cocoa-nut Palms, brought renewed pleasurable feelings; but Calicut being my destination, I was totally unprepared for the glorious sight of cultivated Cocoa and other Palms which met my view as I coasted along the Malabar coast for several hundred miles in a native craft.

At first I was puzzled to know what the green belt reaching to the very sea consisted of. Our craft keeping well off shore, it was not till approaching the port of Calicut that I came to know that this broad evergreen band, reaching for so many hundred miles, was made up solely of Palms, the Cocoa-nut predominating, of course, with an occasional patch of Areca and other species.

On landing late in the evening I was conducted to the house of a friend situated on rising ground, and commanding a full view of this wonderful Palm zone. I slept that night in an upstairs-room with a spacious balcony, used in these hot climes as a promenade in the mornings and evenings. At daybreak I was aroused from a refreshing sleep by a native

servant, who brought me a welcome cup of tea and slice of toast. Light was streaming in by the balcony windows. The sea-breeze had just begun to blow, and I could hear the distant murmur of the waves on the sea-shore, the plaintive screams from the flocks of kites as they flitted past, with heads bent downwards in search of their morning meal. These sounds were all that disturbed the silence of the morning air. As I stepped on to the balcony I shall never forget the sight that presented itself to my gaze. I looked down upon a veritable sea of Palms, gently waving their magnificent fronds in the light morning air. The house was surrounded by them, up to the very walls, and as far as the eye could reach nothing but Palms. Monotonous, you may say; yes, but very grand in its monotony! At that moment I thought of Edinburgh and Kew, and smiled. Mine host joined me on the balcony. I did not wish him good morning, but instead exclaimed, "That sight is worth a hundred voyages from Southampton to Malabar!"

It was difficult to imagine oneself in the midst of a thickly native-populated district, the scene having a certain wild appearance about its giving rise to the thought of the calm solitude of the jungle, and the absence of man. This illusion was quickly destroyed by a subsequent walk through the Palm-groves. Then were seen the innumerable native huts, with walls and roofs composed of the trunks and fronds of their loved Cocoa-nut Palm, nestling amongst the contorted stems of the growing Palms, and effectually protected from the burning heat of noonday by their glorious crowns of spreading fronds. This Palm, as it is cultivated in these climes, has no pretensions to the straight-stemmed dignity of the Areca, that "arrow-shot from heaven," the Palmyra Date, or Caryota; but the groves of stems appear in wanton entanglement, leaning in all directions, but always with the crowns turned heavenwards.

Occasionally, but not often, does the stem divide eight or ten feet from the ground, and produce two crowns of leaves. I do not think that this Palm is included in the list of sacred trees of the Hindus, but they seem to treat it with the same care and affection as if it were. Sometimes they will build their huts around the stem of a Cocoa-palm, thus giving the tree the appearance of having grown through the roof. So far as I can remember, it used to be calculated that each Palm-tree yielded, on an average, from nuts and "toddy" about two rupees (four shillings) per annum, so that an acre of Palms calculating 400 trees to the acre, would yield an annual income of £80, no small sum to a native proprietor.

After a week's stay at Calicut, amongst its Palm-groves, Mango, and Breadfruit-trees, I started for my final destination, viz., the Coffee-producing district of Wynaad in Malabar. To reach this I had to cross the Western-Ghaut chain by a pass in the mountains, and it was thus I first came in contact with tropical vegetation in one of its grandest phases.

Quitting the Bamboo forest at the foot of the mountains, and before reaching the mighty evergreen forest, a belt of sub-arborescent vegetation is encountered. In riding slowly through this I can well remember being struck with the extreme beauty of two plants, viz., *Lagerstroemia Flos-reginæ*, and *Cycas circinalis*. These were growing in abundance, the first-named being prodigal in display of its superb rose-coloured racemes, and the latter growing in large groups among granite boulders, which

it draped with its beautiful fronds. Higher up the western Ghaut forest proper commences, and continues till the crest of the ridge is reached, some 3000 feet above sea-level.

The zig-zag road for a considerable way follows the track of a deep ravine, at the bottom of which one could hear the rushing of a mountain stream, but owing to the dense tropical foliage no water was visible. Before reaching the first thousand feet of elevation, an occasional group of tree-ferns was seen on the sides of the ravine, and the thorny *Calamus* climbing its way to the branches of lofty trees, as if to free itself from the dense foliage beneath, and show to the world its crowns of graceful fronds. As a matter of fact, this was the first wild Palm I had ever seen, but it was — though passingly beautiful — opposed in appearance to the ideas in one's mind of the dignified and independent grace of a Palm-tree proper. Reaching the summit of the Ghaut, it was but a short ride to the first Coffee plantation, where I rested for a day or two, and where I had my first experience of that warm hospitality so well known amongst Europeans in India. Strange that the manager of this plantation should prove to have been an English gardener, the late Mr. James Boosey, an excellent and successful planter, as well as estimable man.

In going the round of the plantation in the cool of the evening with mine host, I had my first sight of the Caryota Palm in a wild state, which had even a greater interest for me at the time than the surrounding fields of Coffee shrubs, the cultivation of which I had come all the way from England to learn. I saw the noble Palm at its best, a little colony of trees of various heights, the tallest bearing heavy masses of fruit, forming a strikingly beautiful appearance. The bipinnate leaves, with their ultimate divisions shaped like the fins and tail of a fish—together with the huge spadices of golden berries hanging from the brown trunks of the highest trees, give them a unique and elegant appearance. Nature, in one of her mysterious moods, has ordained that these wonderful drooping bundles of golden seeds shall be produced on the adult tree first at the top, and eventually at the very foot of the trunk, when the plant dies. She has, however, made ample provision for the reproduction of this beautiful tree by the enormous quantity of seeds produced by each spadix, and the suckers which the tree throws up. This Palm would seem to shun the interior of the dark mountain forests of the Western Ghauts, and it chiefly grows on their outer skirts where, so to speak, it obtains the better opportunity for the display of its graceful fronds, and enjoys that necessary light and air which are wanting amidst the gigantic forest vegetation. It is also curious and interesting to find that wherever a homestead is seen on the edges of these forests, and overlooking the rice-fields, the ryot, in addition to such beautiful evergreen trees as the Mango, Orange, Jack, Roseapple, and others, is sure to have his garden furnished with a small colony of the Caryota Palm, consisting of from six to eight trees from 70 to 80 feet, down to seedlings of some 2 to 4 feet in height. It is not quite clear whether the ryots have selected these sites for their habitations owing to existing groups of Palms, or have reared the trees from seeds or suckers, but the well-known love of the Hindoo for picturesque spots in or near which to locate his homestead, would justify the opinion that previously existing groups of

the Caryota Palm has influenced his choice of a site for his homestead.

On the Neilgherry Mountains there exists a singular race of pastoral folk named Todas, few in number, illiterate, lazy, dirty, immoral, and degraded, and yet these people have admittedly selected the very loveliest and most picturesque spots on all those beautiful mountains for the building of their huts and villages.

That this Palm is known to require plenty of light and air for its development is shown by the fact that when small clearings are made in the forests of Malabar by the jungle tribes for the purpose of cultivating Cardamoms, *Caryota urens* is sure to make its appearance, together with the young seedling Cardamom plants, doubtless coming into existence from seeds which have lain under the thick coating of vegetable matter together with those of the Cardamom, it may be for centuries, awaiting the advent of light and air to effect germination. It is perhaps worthy of mention that Cardamom cultivation in Southern India consists solely in first felling small patches in the great forests, and afterwards simply keeping the brushwood low by one or two yearly cuttings with the bill-hook, the Cardamom plants appearing in abundance and producing fruit in the course of three years without any other cultivation whatever, or artificial sowing of seed. Yet another proof, I think, may be found that the *Caryota* will not succeed in the too close proximity of other trees, in the fact that in the Bamboo or deciduous forests which stretch from the foot of the Western Ghats to the confines of Mysore, occasional patches of evergreen forest occur containing trees exactly similar to those found in the parent forest but completely isolated, and frequently separated by many miles of Bamboo jungle. The soil, too, of these patches in every way resembles that of the western slopes, and is inlaid, as it were, into the black mould of the Bamboo belt. These isolated clusters of evergreen trees are inexpressibly cool and refreshing to the eye during the hot and dry months of the year, and when the surrounding Bamboo clumps and hardwood-trees are destitute of foliage.

The natives have instinctively fixed upon these beautiful spots for the location of an idol, partly surrounded and protected by a wall of rough stones, so that they are all tinged with the glamour of sanctity; and woebetide the person who dares, in any way, to profane these spots.

I can well remember during my noviciate in the Coffee districts, having, from sheer ignorance of how seriously I was offending, felled a tree on one of these sacred places for the sake of its timber, and being pounced upon by the custodian of the temple in the form of an elaborately-dressed Hindoo lady, who first of all abashed and confounded me with a torrent of choice abuse in the Malayalam language, and then demanded the handing over to her, under threat of legal proceedings, of a certain number of rupees, which I was only too fain to do, and thus prevent further trouble. Needless to say, this was my first and last iconoclastic offence.

In each of these romantic spots, and in close proximity to the stone idol, is sure to be found a group of the lovely *Caryota urens* waving their graceful fronds and, as it were, watching and guarding the natives as they come to worship. Amongst the stones, Ferns of various species have taken hold naturally, but giving the impression that they have been placed there by the hand of man.

This Palm, together with its congener, *Caryota sobolifera*, is used in England in sub-

tropical gardening, but not to the extent that its graceful beauty would justify. I would dearly like to see a group of this Palm arranged on an English lawn similar to those I have so often stood and admired in the wilds of Malabar. *J. Lowrie.*

ORCHID NOTES AND GLEANINGS.

STANTHOPEA EBURNEA.

THIS is a pretty white-flowered species of this rather unpopular genus. A plant is now flowering in the Cattleya-house here, and a glance at the flowers, which, with the exception of a few scanty purple markings on the lip, are pure white, at once show its near affinity to *S. grandiflora*, although its odour is scarcely so powerful. *S. eburnea* was introduced in 1828, but was first flowered at Knippersley Hall by Mr. Bateman in 1832. It is a native of Brazil.

LYCASTE SCHILLERIANA.

This strong-growing species is very distinct both in its flowers and the size of the pseudo-bulbs, which bear leaves 2 feet or more in length. The flowers are borne upon long pedicels, and droop somewhat. The sepals are yellowish-green, turning to white at the base upon their inner surface; the sepals also are white, while the long lip is reddish-brown, has a slightly recurved margin, and there are a few hairs under the column. It is a native of Central America, and succeeds well when grown with other species in the Edinburgh Botanic Gardens. *R. L. H., Edinburgh.*

MARKET GARDENING.

WIRE TRELLIS.

(Continued from p. 156.)

As stated in the *Gardeners' Chronicle* for February 5, p. 80, those trellises upon which to train the shoots and branches of Vines and Peaches, the bine of Melons and Cucumbers to in houses, are easily and cheaply made, and these should be fixed forthwith in houses of recent erection. Low, span-roofed houses, having rafters 8 feet in length, will require four 6-foot lengths of 1 inch wide, and $\frac{3}{4}$ -inch thick iron provided with six $\frac{1}{4}$ -inch circular holes at 1 foot apart for fixing the wires to, in addition to two counter-sunk holes (one at each end) for securing same to end wall-plate, and door-posts at from 10 to 12 inches from the roof-glass, and a like distance from the side wall-plate, two of these (one at each side) being fixed as indicated at each end of house or sections of houses, using stout 1 inch long screws for the purpose. This done, secure four lengths of $\frac{3}{8}$ -iron (same width as above), to the end of the wall-plates and the end (principal) rafters, midway putting two screws in each end of these upright strengthening irons, which should be cranked a little at the top to ensure equal space—bottom and top—between each stay and the glass, the framework of trellis being flush with said stays, glass-side. Then pass a 3-inch long galvanised bolt, having an eye at one end to fix the wire to, and a nut on the other, with the thread cut pretty well back to the eye to enable the process of straining one and all the wires being efficiently done. No. 14 wire will be strong enough for all purposes of this kind. One cwt. of this size of wire contains approximately 2,320 yards. Pass the ends of each wire about three inches through the several eyes at one end of the house, and twist them neatly round a few times close up to the eyes with a pair of pliers, then take a length of the wire the full length of the house, cutting it off a few feet longer. Pass the end through the eye corresponding with the one at the other end, straining this with the hands before bending it at the eye of bolt preparatory to cutting it off 3 or 4 inches from that point, this being twisted round the wire as indicated. Then follows the tightening process. Two persons screwing up the nuts (one at each end) same time with small spanners, cycling spanners being convenient and efficient tools. A piece of wire or a brad-awl should be put through the eye when turning the nuts with the spanner. In this way the wires

may be strained as tightly as possible. Small galvanised screw-eyes should be screwed into every other rafter (under-side) at 2 feet apart, those in the second and succeeding lines of wires intersecting each other, with the result that the screw-eyes in each and every rafter are 2 feet asunder, and the wires 1 foot apart, thereby distributing the weight of crop suspended from each trellis equally over the roof-surface. The wires should be suspended from the screw-eyes by hooks made of the same material, 8 inches long (clear), and turned up half-an-inch at each end at right angles, one end being passed through the screw-eye, and the individual wire resting in the other, thus completing a simple and efficient trellis, which is practically on hinges, and consequently admits of the wires being tied together, so as to afford more head-room while the borders underneath are being dug, &c. Moreover, the wires, thus fixed yield easily to "head and back-pressure" on the part of those engaged in the work of training the plants, &c. In the case of larger houses than the one mentioned above, the length of trellis-frames should be determined by the length of rafters, and in order to make the most of internal space, the frames can be bolted together under the apex, where space between floor and bottom of ridge will admit of this being done. *H. W. Ward, Rayleigh.*

(To be continued.)

HARDY PERENNIALS FOR CUTTING.

There is quite a large number of hardy perennials at once suited to present planting, and equally well suited to growing for market. The chief difference between plants so grown for market purposes and the same subjects grown in well-prepared borders, that in all probability have been under cultivation for many years, is the outcome generally either of constitution, or that free-flowering or profuse tendency, which in the end renders the subjects profitable to the growers. There are many beautiful things, too, that are fully as good in a cut state as many I shall hereafter name which, for various reasons, are not profitable when treated in rough-and-ready methods as compared with the gentler art that usually prevails in the garden. In a previous issue of the *Gardeners' Chronicle*, English and Spanish Irises were mentioned by Mr. Ward, and I refer again to these to illustrate what I have just said, because few plants are more beautiful or more suited for sale. And yet how very few of those who have given these lovely bulbous plants field culture can venture to assert they are a really profitable crop when so grown!

Let only those speak who have not less than four or six years' experience of field culture, growing, or at least trying to grow, the same bulbs successfully. In some kinds of soil these plants fail altogether, sometimes even in the early stage; while the instances of success are found chiefly in warm, well-drained soils, and where improved methods of culture prevail. In low-lying clay soils these Irises, or many of them, would fail to put in an appearance in the second year, just at the moment when the flower-farmer is hoping to have nicely-established bulbs. Moreover, it is a crop that the flower-farmer must take to somewhat cautiously, as it is not a difficult matter to bury £100 or £200 in a few rods of ground when planting the most distinct, and therefore the most reliable, of the Spanish Iris. Where previous experience is favourable to them, I say plant by all means at a seasonable moment; but with no past experience to go upon, it would be unwise to proceed. This is the more so when so large a number of profuse-flowering perennials may be quite easily grown, and by the very abundance of their flowers bring in money when the ground occupied is valued in connection with the crops obtained from it. An instance of this may be cited in the Poppy family, e.g., *Papaver nudicaule*, and varieties *album* and *miniaturum*. These, and the Shirley Poppies so-called, though not to be classed as representatives of perennials, are profitable by their very profusion, seeing flowers may be gathered day by day for many weeks together. The same profuse flowering holds sway in *Coreopsis grandiflora*, *C. superba*, and *C. lanceolata*, all excellent, free-flowering, and of good colour. These plants begin to flower quite early in summer,

and continue till frost cuts them off. The first of these is probably the best one. Other good and profuse flowering things are Gaillardias that flower when established from July till late autumn. Seeds of these sown on a gentle hot-bed, similarly to Asters and stocks, and planted in prepared ground in June, may afford a few flowers the first year. If this is not possible the seed should be sown early in July, and planted out in September. These plants are quite

LACHENALIA PENDULA VAR. AURELIANA.

THE figure represents the handsome *Lachenalia pendula* var. *Aureliana* shown by Mr. C. G. Van Tubergen, Jun., of Zwanenburg, Haarlem, at the Royal Horticultural Society on March 8 last. It is not only one of the most beautiful of the *Lachenalias*, but its history opens up a wide field for speculation as to its

FIG. 75.—LACHENALIA PENDULA VAR. AURELIANA: FLOWERS RICH CRIMSON.

was it developed into a much finer thing than any of the wild forms at present known in the Cape? The altered habit of the plant, and its more ornate flowers, seem to say that it was a cultivated plant by the people living near the Via Aurelia, and probably a garden-raised plant, and a selected form, and on the gardens returning to the wild state again in the manner they have been doing over certain areas in all times, the plant has struggled on, sometimes plentiful and sometimes in danger of being stamped out, until history repeating itself, the exploring party again secures its place in gardens. The same might be said, probably, of many a new introduction which had been cultivated and again run wild, for although in every age gardeners think themselves the first to really pursue the calling energetically, the most ancient history, and the oldest works of art, tell us of gardening as intelligently pursued thousands of years ago as at the present time.

African plants seem to have been widely distributed in the early ages, and run wild, and as evidence, it is on record that some of the African Iridaceae and Amaryllidaceae have been gathered wild in South America. For example, some years ago, Messrs. Low's collector gathered wild, and sent home as a new plant, *Amaryllis Belladonna*, whose coats of silky threads tells us plainly its African origin, as do the net-like tunics of the *Watsonias*, *Gladiolus*, &c. On the other hand, the thin-skinned S. American bulbs have been found in Africa; and, as a reasonable solution, it is suggested that the slave-traders have been instrumental in bringing about the exchange. The flowers of *Lachenalia pendula* var. *Aureliana* are of a rich crimson colour. The flowers are numerous and handsome, as will be seen by reference to the illustration, but the effective buds do not continue to the apex as there seen, but a few at the extreme point are abortive. It flowers about a month later than the type. J. O'B. [The introduction must have taken place in pre-historic times, surely! Ed.]

THE CULTURE OF CATTLEYAS.*

In the year 1817, 78 years ago, the naturalist, William Swainson, was roaming about in his hunting-ground, as he called it, in the interior of the Brazilian forests. Here he discovered a wonderful flower of indescribable beauty, of which he had never seen or heard before.

The plants are pseudo-bulbous Epiphytes in character and habit, growing on the trunks and large branches of trees, with large numbers of lizards and brilliantly-coloured small snakes of different kinds disporting themselves upon the trees and among the flowers; and the stream, which meandering through this virgin wood, passed immediately beneath the new treasure, swarmed with long-nosed alligators. With considerable difficulty Mr. Swainson procured some of the plants and sent them to this country, with as realistic an account of their nature and beauty as was in his power. Their arrival in England, accompanied by such a glowing account from such a man, created a large amount of interest, if not excitement, among the then limited number of Orchid-growers. And in course of time, when it developed its inflorescence, and displayed to the expectant Orchidist, the grandeur and beauty of our now well known *Cattleya labiata*, we cannot wonder at the great sensation that was caused among the ardent lovers of this interesting and curious family of plants.

I have not been able to find out who was fortunate enough to be the first to flower this new Brazilian wonder in this country. But the botanical science of the early part of the century could not ally it to any other genus of the Orchidaceae, therefore a new genus must be created for it. Accordingly, Dr. Lindley named it *Cattleya*, in honour of W. Cattley, Esq., of Barnet, Herts, a famous patron of botany and the foremost Orchid amateur of his time.

Since that time, many other species have followed, such as *intermedia* in 1824, *crispa* in 1826, *guttata* in 1827, *Mossie* and *Skinneri* in 1836, *citrina* in 1838, *granulosa* in 1841, *lobata* in 1847, *Trianae* in 1856, and *Dowiana* in 1866, and many others, until at the present day there are over fifty species, and more than 160 named varieties, so that there are in all over 200 named *Cattleyas* introduced to this country from different parts, including South and Central America, Brazil, Colombia, Rio Negro, Costa Rica, Ecuador, Mexico, Essequibo, British Guiana, and Venezuela. Besides this, there have been several very beautiful hybrids raised in this country of late years. Perhaps the most beautiful of all the British hybrids is the one that flowered at St. Albans last year, and named "Lord Rothschild."

* Read before the Members of the Devon and Exeter Gardeners' Association recently, by Mr. George Lee, gardener to Miss Lavers, Upton Leigh, Torquay.

hardy, and young plants especially so; and a good strain of *G. grandiflora* will produce almost all the named varieties of this used in commerce. Two good plants not usually grown are *Galega officinalis*, and *G. o. alba*, the last well nigh indispensable. *Lathyrus latifolius albus* is another profitable plant, a row of this 100 feet long, supported by a few rough sticks, would in the second and third year produce a surprising lot of pure white material. E. Jenkins, Hampton Hill.

origin. A botanising party found a single clump of it growing near the summit of Mont Esterel, Alpes Maritimes, in the south of France, in the spring of 1889. As the ancient Roman Via Aurelia is near the place where it was found, a local botanist, the Abbé Pons, named it *L. pendula* var. *Aureliana*. Now, *Lachenalia pendula* and its congeners are natives of South Africa, and therefore it could not be naturally indigenous in the South of France; and the question arises, how did it get there, and how

CULTURE.

In dealing with the culture of these plants, I shall refer to the teachings of others here and there, but I shall confine my remarks mainly to my own experience and my own opinion on the cultivation of Cattleyas.

In order to grow Cattleyas successfully, there must be a suitable structure set apart for their accommodation, or if they have to share the house with any other class of plant, the others must be the subordinate, and take their chance under the treatment that the Cattleyas require; for although most Cattleyas are not very difficult to manage, if you understand their natures and can comply with their requirements, yet I know of no class of plant more exacting or less willing to accommodate themselves to their new surroundings if they are not exactly suitable. To try and get them to take their chance in a house under general treatment with other plants will generally result in failure in a year or so.

The house to grow them in should be either span or three-quarter span-roofed. I prefer the former, built in as light and airy a position as can be found, and should face the sun as much as possible. No wood staging should be used, but all benches should be either slate, cement, or corrugated iron and these, together with the floor, should be covered with shingle or fine gravel to the depth of 2 or more inches, to hold moisture. At some seasons of the year, many of the Cattleyas are benefited by being suspended from the roof; it is wise to make the roof extra strong, and large hanging rods should be placed at regular intervals. Also in the roof, as well as in the front sashes and the brickwork beneath, there should be ample means for an abundant ventilation. Then a heating apparatus should be applied of sufficient power to keep up a temperature of 55° in the coldest weather.

Another very important matter is the grooving of the rafters longitudinally, so as to carry off the drip, instead of allowing it to drop on to the plants. Irreparable damage has been done to many a costly Cattleya through the neglect of this precaution. There must also be made ample provision for water. But this is not always to be accomplished as the cultivator would like. I should say, by all means save the rain-water, for there is nothing equal to it for Orchids, nor, indeed, for any other plant. But I could not advise a large tank, with a body of from 2000 to 3000 gallons of water in it in a Cattleya-house, as I should do in an Odontoglossum-house; but rather a small tank with from 60 to 80 gallons of water, to be replenished from a larger one day by day. Light blinds should be fixed outside the house, to be used in very hot weather, if the cultivator should think it best to do so. Of course, the size of the house must be decided according to the requirements of the case.

IMPORTED PLANTS.

In my experience, unfortunately, I have had to do largely with imported plants; that is, plants as they come home from abroad. But I am bound to admit that the cultivator's success depends largely in the first outset on the collector's discretion, for if the plants are not gathered at the right season, the cultivator will have a far more difficult task in establishing and making good pieces of them. I have seen scores of grand pieces of Cattleya completely ruined from having been gathered while in a growing state. When this is the case, you may be as careful as you can with the immature growth, but in nine cases out of ten it will die away, and the leading eye will die with it. Then you have to start with a back growth, and it will usually take years to get it up to a flowering state.

But we will suppose that we have an importation in good condition, that is, with the last made growths thoroughly ripened before they were gathered, and with the leading eyes sound but still dormant. In this condition they will keep a long time, suffer many hardships without being injured.

The first thing then will be to clean them. Mr. Williams, in his *Orchid Growers' Manual*, says they should be sponged over. But I say they should be scrubbed. Take a tub, or pail that shall be large enough to submerge the whole of the plants at once, have some soft-soap thoroughly dissolved, and so fill your tub with a solution strong enough for cleaning glass and wood-work, say rather more than an ounce of soap to the gallon. The temperature of the water should be about 90°. Let the plants remain in this for two hours, when they should be thoroughly cleaned with a scrubbing-brush, leaves, bulbs, and roots. After which they should be rinsed in clean lukewarm water and drained. Then they should be closely examined, and with a sharp knife all signs of decay cut away. All dead roots, and all living ones that show any signs of having been bitten or punctured by insects, and any pseudo-bulb with a hole in it should be cut clean away, or the hole cut out. Only in this way can one make sure of being rid of scale, cockroaches, and the Cattleya-maggot, on which I shall say more further on.

After the plants are drained, a piece of cord should be put around each mass, and they should be hung up to the roof in the shadiest part of the Cattleya-house, with the leaves hanging downwards. They must be shaded from the hot sun if it be spring or summer, and syringed or dipped every day or two, according to weather and the time of year, but not too often, providing there is an abundance of atmospheric moisture in the house. I have found this the best way to induce root-growth, and as these appear the plants should be reversed, and hung up again with their roots downwards, where they remain until these are from half an inch to 1 inch in length, when it is time to pot them. I have found this to be the best way of starting Cattleyas of every kind that I have had to do with except three—Eldorado, Superba, and Schilleriana. These, instead of being hung up in the

Cattleya-house, should be put in the East Indian-house; or, in fact, in the hottest place you can find for them, providing there is sufficient moisture in the air.

POTTING.

The essential requirements for potting Cattleyas are these—clean pots, or teak-wood baskets; plenty of clean potsherds, varying in size from half-an-inch to 3 inches; rough fibrous peat, broken up into small lumps, in size from that of a blackbird's-egg to that of a hen's-egg, and with all the earthy and sandy particles beaten out of it; also clean living sphagnum and charcoal. Many recommend coarse sand, but I have discarded it for years, as being of more harm than good for Cattleyas. Some recommend putting equal parts of peat and sphagnum, adding a quantity of potsherds and charcoal, and mixing it altogether on the bench. But I prefer to have the ingredients separate, but within easy reach, and use from each as I proceed. Then have a pot, according to the size of your plant, not too large, nor too small, but just to allow the lead of the rhizome to be well back from the edge of the pot. To support the plants, have two or more stiff sticks, which should be inserted among the drainage, right down to the bottom. The drainage should occupy two-thirds of the pot, and the sticks kept in their proper position among it. Cover the drainage with a layer of the sphagnum, then fill up the remainder, mixing in the material as we go on, putting plenty of lumps of sherds and charcoal with it to keep it open, and ensure a free passage for both water and air. If the plants have any roots, they should be placed in position and the material packed carefully around them. But if they have no roots, they should be placed on the top of the material, and fastened firmly to the sticks.

In nearly all cases of pot culture, the plants should be raised above the rim of the pot, say from one to three inches according to size. If using baskets, you need only cover the bottom with large pieces of sherd and charcoal, and then proceed as in the case of pots. But in all cases, the material used should be packed and pressed moderately firm, and the plants securely fastened to the sticks, so as to prevent any movement until the roots have obtained a firm hold upon the material that has been supplied for them. And then after they have been potted, they may be watered carefully, and put into their respective places in the Cattleya-house according to the sorts and the season of the year.

I think it is of little importance whether they are grown in pots, pans, or baskets. But most growers have their fancy, and most like to use a portion of each, for I think it looks more like Orchid-growing to see some baskets and Orchid-pans with holes in their sides than it would to see only ordinary pots as in a collection of other plants.

I prefer ordinary pots for such Cattleyas as *gigas*, *crispa*, *lobata*, as well as for those of the *guttata* group, and *Leelia purpurata*, they are of strong growth, and usually make a quantity of roots. But the smaller and more compact-growing species, such as *Warneri*, *Schroderae*, *Percivaliana*, and *dolosa* might be grown with advantage in baskets and shallow pans; but every careful cultivator will soon find out which will best suit his plants and his purpose.

Cattleyas, if properly treated, will not require potting again for two or three years. Each year as the season comes round for them to start into growth, the dry and rough material on the top should be carefully picked off and replaced with fresh.

But in growing on a collection of established plants, as I have done for nearly twelve years, we shall find each year there are some among them which require a thorough overhauling and repotting, and this is a work which, even by the experienced cultivator, requires great care and judgment in its performance, and is often entered upon with considerable trepidation, especially if the plant under operation should be worth 50 or 100 guineas.

A gentleman, a grower of Orchids in Yorkshire, who is well known in Torquay, in speaking with me on this subject on one occasion, made this remark:—"They should never be so treated until they cry for it, and then it must be done, but with fear and trembling." It often has to be done, and this is the way in which I usually proceed. If there are any living roots attached to the pot, it (the pot) should be broken, rather than run the risk of destroying the roots by pulling them out. Then carefully pick off all the old material, and wash the roots and rhizome of the plant in lukewarm soapy water. Then with a sharp knife cut away everything of root or branch that is dead or dying, and repot as directed for imported plants. This work should be done immediately the eyes begin to swell for starting into new growth.

(To be continued.)

NOTES FROM A LITTLE CORNISH GARDEN.

(Continued from p. 156.)

MARCH 1.—"A tear the Paphian sheds for each blood-drop of Adonis, and tears and blood on the earth are turned to flowers. The blood brings forth the Rose, the tears the Wind-flower." Well may the scarlet flowers of *Anemone fulgens*, with their jet-black centres, dazzle the mere human eye; for one has but to see them to be convinced of the truth of Bion's story of the plant's origin. It is our most brilliant spring flower; and fortunately it is easy to grow if but left undisturbed. The light and elegant bearing of the flower-stem, and the grace of the

foliage, but serve to make more valuable this perfect flower. In addition to the ordinary kind, I have some of the variety known as Sutton's, whose flowers have a yellow centre.

The blue *Anemone appennina* of Italy has long been in flower, and shows no sign of stopping yet. It literally cushions the ground with its foliage and large sky-blue flowers. The white variety is also very beautiful. *Anemone blanda* is very similar in colour and habit, but blooms some weeks before *A. appennina*. Several varieties of the Wood *Anemone* are of great beauty. I have, in addition to masses of the single and double common varieties, clumps of *A. nemorosa Robinsoniana*, with beautiful large opal-blue blossoms, and of *A. nemorosa bracteata*, with double white flowers quaintly resting on green bracts. The golden *A. ranunculoides* rather reminds one of the lovely buttercups of May. I might go on describing the various kinds of *Anemone* which are worth growing for their beauty until every known *Anemone* were included in the list.

I am trying to grow all the kinds in the florists' catalogues, and each is lovely and interesting. Of course, everyone grows at least a few hundred of the very varied *Anemone coronaria*, which is so useful for cutting, as well as so illuminating in the early spring garden. The mass of carpels in the centre of many of these flowers makes a good landing-place for insects, who come for what they can get from the *Anemones*. This is chiefly pollen, for few of the *Anemone* species produce any honey; bees must go elsewhere for that, and have been seen by Müller to alternate their pollen quest with the search for honey in other flowers. Their pollen is thus the entire stock in trade of the *Anemones*, and they are wisely careful of it. At the smallest sign of rain, and at the onset of dusk, the perianth domes over the centre of the flower, and in many cases the flower-stalk bends that the flowers may droop, and so further protect the valuable powder within. By the way, it will be noticed that most of the white *Anemones* which adopt this habit of periodic opening and closing have their sepals tinted palely blue or red on the under surface. It is believed that this pigment, anthocyanin, has the property of turning light to heat, and so from earliest dawn to the opening of the flower, accumulating a store of useful energy for the plant's use.

My Primroses are almost at the height of their glory. I spoke last month of being able to pick hundreds of blooms from a little border. At the present moment I might pick many thousands from the same border, and (this is the value of the Primroses) I should have as fine a display as ever in less than ten days.

In my January notes I complained of Herrick's simile of primrose colour as like to those with "green-sicknesses." Since then I have come across a much pleasanter reference in Roden Noel's splendid poem called "Early April":—

"Virginal purity of pale Primroses!
Petal on petal of a sister repose,
And the shadow of either on either dozes."

Of the Daffodils it seems useless to speak. For elegant, classic beauty of form and delicacy of colouring, what can be compared to them? Keats names them as among those things of great beauty whose joy is perennial; Shakespeare and Wordsworth have recorded their loveliness; and Herrick wrote, perhaps, his best-known verses regretting the Daffodil's fragility of life-tenure. The more one grows them the more one sees to admire in them. Nearly all the varieties in the florists' lists—and there are some hundreds—are of great beauty, and there are interesting—though sometimes small—differences between them all. Trumpet Daffodils with white wings, others with sulphur wings, others self-coloured—golden or pale yellow—throughout; Star Narcissi, with every depth of cup, Narcissi with recurved sepals like Cyclamen flowers. Daffodils that look up, Daffodils that look down, and others that look you straight in the face.

Obvallaris, Horsfieldi, Sir Watkin, Emperor, Queen of Spain, Mrs. Langtry, Golden Spur, Gloria Mundi, are but a few names; yet what a picture they

call up in our minds! Daffodils may be purchased in quantity in many beautiful kinds for a small sum, yet it is a dangerous pastime to study such a publication as Barr's *Catalogue of Daffodils*. One is far too apt literally to take Mahomet's advice—"He that has two cakes of bread, let him sell one of them for some flowers of the Narcissus, for bread is food for the body, but Narcissus is the food of the soul."

I have been planting out a few of the lovely new Martin Smith self-coloured Carnations, as well as some old Clove and white Clove. My soil is much too light, but I am trying what plenty of decayed manure about the roots will do. I have been sowing some dozens of packets of seeds in pots, and have the daily joy of opening my frame to see what new seedlings the last twenty hours have brought above earth. I have up already some six varieties of Columbine, several species of Campanula and Primula, as well as a lot of new Primroses and Polyantheses, from very choice seed. Every morning it is almost exciting to walk round the garden in wonder as to what new flowers have just appeared. Advance Tulips, Roses, and the rest, give as much pleasure of a kind as the gorgeous displays which we expect from them in due season.

The spring really is coming. No swallow makes a summer, nor any flower a spring. For months past we have had flowers, but spring is now evidenced by ten thousand co-acting events:—

"Blows the thaw-wind pleasantly,
Drips the soaking rain;
By fits looks down the waking sun,
Young grass springs on the plain.
Young leaves clothe early hedgerow trees;
Seeds, and roots, and stems of fruits,
Swollen with sap, put forth their shoots;
Curled-headed Ferns sprout in the lane;
Birds sing and pair again."

It is tempting, it is almost defensible, to quote the poets when writing of the spring. At any rate, I must ask excuse for referring to some lines of Miss Nesbit's, which will probably not be familiar:—

"And spring is here—but with the spring
Come bitter winds, and cold, cold showers;
Will these not slay the wakening flowers,
And stay their buds from blossoming?
No—in despite of wind and rain,
The year will add to flowers new flowers;
Till summer comes with burning hours,
And all the Roses live again."

Which inevitably recalls poor Philip Bourke Marston's *Before and After Flowering*, where the Violet, just before the dawn, calls to its sisters of yesterday, but receives no answer, for the frost has done its work:—

"No pleasant wind about the garden goes,—
Perchance the wind has gone to bring the Rose.
O, sisters! surely now your sleep is done,
I would we had not looked upon the sun,
My leaves are stiff with pain. O cruel night!
And through my root some sharp thing seems to bite,
Ah, me! what pain, what coming change is this?"

Instead of dreaming in this fashion, however, honest gardeners must set to work sowing their seeds and finishing their spring plantings, or they will find themselves without any flowers to poetise over and enjoy. *Harry Roberts.*

ALOE SCHWEINFURTHI.

WITH regard to this rare species of Aloe, Mr. Alwin Berger, Curator at La Mortola, writes:—"I send you a photograph, taken by Mr. D. Hanbury, of a fine specimen of Aloe Schweinfurthi now (January 31) in blossom in the garden of Commendatore Th. Hanbury at La Mortola. This beautiful Aloe, as your readers probably know, is a native of Niam-Niam-land, in Central Africa, and was named by Mr. J. G. Baker, of Kew, after its discoverer, the distinguished botanist and traveller, Schweinfurth. The large thick leaves attain a length of nearly 70 centimètres (2 feet 3 inches), with a breadth of about 18 centimètres (7 inches). They are of a dull glaucous

green, with a narrow red border studded with distant teeth. The inflorescence is more than a mètre (39½ inches) in height, divided into numerous branches, each of which bears a spike of about a hundred beautiful closely-packed flowers. These are of a bright coral-pink, and last a long time. The seeds of this interesting plant were distributed from this garden two years ago, and it is to be hoped that the plant may be found worthy of cultivation in English gardens. The climate of the Riviera is undoubtedly one best suited to the Aloe family, and the rich collection at La Mortola shows what can be done in that direction. At the moment there is also

FIG. 76.—ALOE SCHWEINFURTHI.

in bloom another most striking arborescent species, which somewhat resembles the old Aloe arborescens, Miller, but I cannot identify it with any description or figure, and believe it to be a new or undescribed species.

CULTURAL MEMORANDA.

GLADIOLUS FOR LATE FLOWERING IN POTS.

IT may be useful to call attention to the great value of Gladiolus of the gandavensis section for greenhouse and other decorative purposes. By potting corms in the month of May, flowers are obtained in the period of September to November, according to the varieties, at a time therefore when flowers of any kind are rather scarce indoors.

Place one large corm in a 6-inch pot in a soil con-

sisting of two-third parts of loam, one-third decayed manure and a small quantity of sand. During the early stage, slightly cover the pots with coal-ashes out of doors, and remove the ashes down to the soil when growth has begun. As a rule, one corm in a pot is preferable to two or three, as it may happen that all the flower-spikes in a pot will not open at the same time. If the autumn is wet, remove the plants to a glasshouse.

TORENIA FOURNIERI.

This pretty plant, having a somewhat upright habit of growth, reaching to a height of 8 to 12 inches, is of varied usefulness. If treated as an intermediate-house annual plant, seeds may be sown in March, and as late as the end of April in heat, pricking off seedlings when they are large enough to handle into pans, afterwards potting them singly, and affording one or two further repottings, the largest pot being one of about 5 inches in diameter. Loam and leaf mould in equal rates, with a small portion of sand, make a suitable kind of compost for Torenia. During growth the points of the shoots should be pinched twice or thrice to ensure bushiness of growth. The plant, after getting established in the last shift, may be placed in an unheated pit till the flowers expand. This kind of treatment only holds good in the warmer parts of the country; and in others an intermediate temperature is best. *J. Baxter, Boldre Grange Gardens.*

TRACHELIUM CERULEUM.

This plant will be found a very useful one for the greenhouse and cool conservatory, during late summer and autumn, and the flowers are of a colour that is not too abundant at that season. Seeds of the plant may be sown at about this date and earlier, pricking off the seedlings to the number of three or four round the edge of a large 60-pot, in peaty soil, and either shifting the potful intact, or singly, and pinching out the points to induce several trusses of bloom to come in place of the usual one. If to be used as an edging to small groups and stages, 5-inch pots are a useful size, but larger pots should be used if large plants are wanted. *H. Markham.*

GARDENIA GRANDIFLORA AND G. RADICANS.

I make a practice of striking cuttings of Gardenias early in the spring, before, therefore, the sun gets much power, and obtain strong plants in the course of the season. I have had plants from an early strike which have produced sixty blooms apiece in about 1½ year from the cutting stage. I make a practice of stopping the strong shoots three or four times at an early period, and frequently apply soot-water, and occasionally a sprinkling of an artificial manure when the plants have plenty of roots. *H. Markham.*

CURCUMA ROSCOEANA.

This handsome species of the extensive genus of Gingerworts has of late years fallen into comparative neglect, which is somewhat remarkable, seeing the species generally are of easy culture, and this one makes a fine display in the warm conservatory and stove in the autumn months. Another advantage that Curcuma Roscoeana has, is the long time it lasts in bloom; and even when not in flower, its spreading light green leaves, which are, when fully developed, about 18 inches in length, have a fine appearance. The erect flower-spike is about 8 inches in height, thickly furnished with scarlet flowers and orange-coloured bracts. The plant is a native of the East Indies, and stove treatment is proper for it when making its growth, although it will stand a long sojourn in the cool conservatory during August and September, its flowering season. The best kind of soil for growing this plant is one that consists of peat two parts, and of loam and rotten dung each one part, to which a good deal of sand should be added. Propagation is best effected by division of the roots in March or April, when repotting the plant. As soon as the flowers begin to fade, remove them, and let the plant gradually ripen off, and store under the stage in a warm house for the winter. *H. T. M., Stoneleigh.*

NEW INVENTION.

MINIATURE FOUNTAINS.

IN countries where hot temperatures and excessive sunshine occur, the use of small water fountains in the sitting-room, is pleasant and refreshing. Not only does the spray tend to lessen the heat of the atmosphere, but it imparts some degree of moisture to same, whilst the sound of rippling water in such circumstances is most enjoyable. They are seldom used in our own country in sitting or drawing-rooms, but occasionally one may be seen in the entrance-hall, and more frequently in the conservatory. The latter structure is the most suitable place for one, and to such a house a fountain is undoubtedly an attraction.

Our attention has recently been directed to a particular kind known as the "Hot-air Motor Drawing-room Fountain," which though not absolutely new, may be unknown to some of our readers. The necessary heat is supplied by a spirit flame, enclosed in a stove, and the motor is a little expansion machine, which works smoothly and quite noiselessly. The motive power obtained is transferred to a suction and pressure-pump, which forces the water from the aquarium, into a jet as much as six feet high. The water is of course restored to the aquarium, and thus is kept in constant circulation; consequently fishes thrive in it. The water is also prevented from becoming warm by any contact with the heat from the spirit lamp.

The fountain may be kept working the whole of the day without attention, beyond supplying a little oil. The machine is made of metal castings, and stands upwards of three feet high. On the table below the octagonal glass-panelled aquarium, space is provided for placing decorative plants. Several jets are provided, and various modifications can be made in regard to the method of providing motive power to the pump. It requires very little attention, and where a fountain is desired, may claim attention.

Like many other inventions, this one is "made in Germany," but may be procured in London.

SCOTLAND.

LECTURES ON LANDSCAPE GARDENING.

MR. HENRY E. MILNER, F.L.S., V.M.H., &c., is now engaged giving a course of five lectures, in the Botanic Gardens, Edinburgh, to gardeners and foresters. These lectures are in connection with the classes held for gardeners and foresters employed at the Botanic Gardens, which have been successfully running for some years. They were instituted by the Regius-keeper, Professor J. B. Balfour, F.R.S., &c., who has consented to the admittance of those interested in the subject of the lectures which Mr. Milner is giving. The first lecture included the Introduction, the Development of Landscape Gardening, and the Enunciation of General Principles. A good assembly was present in the Lecture Hall to receive the lecturer, who after being introduced by Professor Balfour commenced by giving a sketch of the early gardening in the East, in Chinese, and Roman gardens, down to the present time, giving the special points which the known landscape gardeners excelled in at the close. Towards the finish, Mr. Milner spoke of the utilisation of water in the beautifying of our gardens, referring also to the utility of the formal treatment of ground near the house, showing also the use of colour in promoting an idea of distance. The following lecture treats upon the subject of site, the approach, the terrace, and kitchen garden. The third deals with drainage, water, structures (steps, walks, bridges, &c.). In the fourth, the formation of the ground, and planting is considered; while the last considers the extremely large subject of Design. Other courses to follow the one now in progress are:—A course of ten lectures by Dr. A. P. Aitken on "Manures, and the Application of Chemistry to Horticulture and Forestry." Baillie Mackenzie (of the firm of Mackenzie & Moncur) gives lectures on "Horticultural Building, Heating, and Ventilation." While the "Valuation of Woods and Plantations, and the Sale of Timber" is to be taken up by Mr. D. F. Mackenzie, of Morton Hall.

[In future issues we hope to be able to publish the substance of Mr. Milner's lectures, for the benefit of our readers generally. ED.]

THE WEEK'S WORK.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Greenhouse Rhododendrons.—The white-flowering varieties, such as R. Princess Alexandra, Countess of Sefton, Countess of Dalkeith, and Duchess of Sutherland, which are most useful for Easter decorations, may be gently forced if not now in a sufficiently advanced state, but on no account should they be unduly hastened into flower, or the blossoms will fail to develop in a proper manner, although the house in which they are forced may be kept moderately close and the air moist, and the syringe freely used to prevent the spread of thrips on the plants. Let the plants stand on spar, coal-ashes, &c., and do not let them become dry at the root at any time. Young plants of those Rhododendrons which are growing thin or mis-shapen may have the flowerless shoots pinched at the points, in order to induce breaks, whilst flowering shoots will break without pinching. The main stock of plants that may not be forced should be afforded a cool, well ventilated house. Young flowerless plants may now be repotted, and flowering ones after the chief burst of bloom is past. Like Ericas, they are healthiest when afforded pure fibrous peat, plenty of sand, and pots very well and carefully drained. A larger shift than 1 inch all round the ball should not be given.

Daphne indica.—This plant and its varieties and D. odora succeed under similar culture to that required by the greenhouse Rhododendrons, and they will grow with care into good large specimens. If forcing is resorted to, it must be carried out with moderation, for the reason that all Daphnes resist a close, moist atmosphere if placed in it for any length of time, and also if pushed on rapidly more harm than good will result. When Daphnes are in free growth, the house may be closed early in the afternoon, after affording the plants a good syringing. Water must be carefully applied, the happy medium being aimed at of affording neither too much nor too little water. Any of those plants which are in need of repotting may now receive attention, affording them a good drainage, and a compost that consists of fibrous loam, a large proportion of coarse silver sand, and a sprinkling of bone meal; pressing the soil firm round the roots. Any plant which has plenty of healthy roots, but has made straggling growth, may be cut hard back. The shoots will break freely soon afterwards, and in two seasons healthy flowering plants will result. Shoots that fail to flower must have their points removed just previous to the flowering of the plant, then all the shoots will start into growth at the same time.

Poinsettias.—When young shoots are used as cuttings, some of the plants should be placed in heat and well syringed, the shoots being taken when they are 3 inches long, and with a heel. Without making any more wounds insert them simply in thumbs, using a light sandy soil, putting some silver sand at the base of each. The readiest means of propagating Poinsettias is to cut the old stems and branches into two-joint lengths, and insert these in thumbs. These soon root in a close frame or case on bottom heat or without it.

Euphorbia Jacquinæflora.—Place the old plants in heat in order to induce growth, and when the shoots are 3 inches long, remove the plants into a cooler house for a few days before taking off the shoots with a sharp knife just where they issue from the old stem. Trim off the lower leaves, and insert round the sides of small pots in sandy soil, and keep close and shaded. Last year's plants that have been pruned back, if growth has commenced, may be shaken out and repotted, and afforded an intermediate-house temperature.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

The latest Vines.—The disbudding of the canes should be carried out as soon as it can be seen which of them show bunches; and the number of shoots to leave on each spur will depend upon the distance the spurs are from each other on the rod, but as a general rule a sufficient number should be left to furnish the trellis without crowding taking place when the leaves are fully developed. If the spurs are about a foot apart on each side of the rod, one shoot from each will be sufficient, preference being given to the strongest that is showing fruit, and which starts from a point near to the rod. Where spurs are further apart than 1 foot,

space may be found for two shoots from each spur, one with a bunch, and the one that is nearest the rod without one.

Syringing Vines.—Very frequent syringing in dull weather after Vines have broken causes the rotting of the shoots, but if there is a danger of red spider infesting the foliage before the flowers expand, syringe the Vines on fine days twice a week, a thorough application doing much towards clearing off the pest. The morning is the best time for syringing Vines.

Melons.—When the main shoots of the most forward plants have spread over the trellis to their allotted distance, stop them, and by so doing, strengthen the weaker lateral ones. Laterals coming out of the main stem for some distance up do not usually show any female flowers; if those near the bottom of the trellis also have no female flowers, nip them off in front of the first leaf, and the second shoots will most likely show fruit blossoms. Lateral shoots which show fruit blossoms should be pinched two leaves in front of the first blossom. Male flowers, as a rule, are plentiful enough, and in order to make sure of a good set, go over the plants every day about noon, and set any expanded fruit flowers, pinching off all the male flowers then expanded. The leaves should be left on the secondary shoots, one leaf or more, so as to get the trellis covered fairly. All young shoots that appear after this is done must be rubbed off whilst quite small. During the process of setting, the syringing of the plants should be discontinued, and the soil of the hillocks or bed allowed to become rather dry, the soil and floor of the house being damped only once a day, in the afternoon. Having obtained from three to five healthy fruits per plant, recommence the application of water whenever the condition of the soil shows it to be necessary, affording manure-water occasionally. Let a genial growing atmosphere be maintained, and ply the syringe thoroughly on the foliage on fine days, once at closing time, and at other times when needful damp the floor and surface of the bed, but do not cause excessive dampness, as that favours soft growth and the canker of the stem at the ground-level; and do not cause a check by removing a large quantity of leaves and shoots at one time. If the bine has frequent attention in stopping and thinning, there is no need to use the knife. If aphides are troublesome, fumigate or vaporise without delay. Maintain a temperature of from 65° to 75° by night, 75° on dull days, and 85° by sun-heat, and 5° higher for a short time after closing the house. Let air be admitted by the upper ventilators when the temperature has risen to 80°, and increase the amount before 85° is exceeded. In the daytime, while the plants are in flower, keep the hot-water pipes rather warm. Successional Melon plants may be planted, and seed sown.

Cucumbers.—When the last top-dressing of soil is filled with roots, another one may be added, and stopping, thinning, and securing the shoots attended to. Stop leading shoots that have grown some distance and size in order to get a sufficient number of laterals to cover the trellis without crowding it, pinching out the surplus shoots. Apply water when the soil is getting dry, and syringe and damp down several times daily. Maintain the same temperature for Cucumbers as for Melons.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Thunias.—T. Marshalli, T. Bensonæ, T. Veitchiana, T. Brymeriana, T. pulchra, T. alba, and the pure white T. candidissima, are valuable, for they are distinct from most Orchids in form of flower and habit of growth. The plants are now making new growths, and no time should be lost before shaking them out of the old compost and repotting them. The practice of growing about half a dozen pseudo-bulbs, 3 inches apart in a good-size pot, is a convenient one. Make the pot half full of drainage, and cover with a layer of turfy loam, laying the grass side downwards, into which the roots will probably enter about the time the flower-buds show. Keep the young growths just below the rim of the pot, and fill up to their base with peat and moss, adding a few handfuls of crocks, and a little silver sand. Make the compost moderately firm, and tie each bulb to a neat stake, afterwards placing them in the lightest available position in the East Indian house. If the bulbs are extra long, carefully bend them over at the top, and tie them down, so that the young growths may be brought up as near to the roof-glass as pos-

sible. Water sparingly, but increase the supply when fresh roots are apparent. Immediately the flower-spikes appear, afford the plants an occasional application of weak liquid-manure.

Dendrobium spectabile.—This undoubtedly beautiful and distinct species, which has been imported of late in large numbers, is worthy of the utmost attention on the part of cultivators of Orchids, and a few hints on the management of newly-imported plants will be of service to tyros and old hands alike. On a plant being received it should be sponged to free it from dirt and insects, the decayed parts removed, and then it should be put into a pot that will suffice as regards size for one season only, the pot being nearly filled with crocks, and the plant made steady by tying the pseudo-bulbs to sticks—a very important matter. Although this species comes from a country with a very warm climate, no effort should be made to force the growth or plump-up the pseudo-bulbs at once, but everything should be gradually carried out; and for the present, the plant may be placed in a house that is moderately cool and dry, and no water afforded for a few days, after that lapse of time a small quantity of water may be poured amongst the crocks occasionally, but no wetting of the base of the pseudo-bulbs should be done, and I would not advise the damping of the plant overhead before full establishment, the pseudo-bulbs being very apt to be blackened, a state that leads to decay. Keep it shaded from strong light and the direct rays of the sun, and as soon as signs of revival are remarked, remove it to a warm shady part of the Cattleya-house, and when new roots are seen let peat and sphagnum-moss be firmly placed around it in the usual manner, and place the plant in the warmest house. After this potting, light applications of water may be made, great care being taken not to afford too much. As the plant grows at the root and top, and gains strength generally, water will be more frequently required. From my limited experience (of about two years) of this plant, it likes, when established, water to be copiously afforded the whole year, and to be well shaded from the sun's rays.

Cattleya labiata.—Freshly-imported plants require a similar kind of treatment till new roots or growths show, when repotting may be done, and the plants placed with others of the same species.

Calanthes.—The plants of the deciduous section may now be repotted, that is, as soon as the new growths are about $1\frac{1}{2}$ inches long, and before young roots are made. The latter of course is the safer one, there being no chance of injury being done. Before proceeding to repot a plant, turn it out of its pot, shake off the spent soil, and shorten the dead roots to within an inch of the base; what is left will help to keep the plants steady in the compost. This may consist of good fibrous loam one half, dry cow-manure or good oak-leaf mould one fourth, finely chopped sphagnum moss and small crocks one fourth, and a moderate quantity of coarse silver sand. Clean pots should be used, the sizes and the number of bulbs in each pot being varied according to discretion. Where space is of no account, it is an advantage to grow the plants singly in pots proportioned to the sizes of the pseudo-bulbs. *Calanthes* require good drainage, crocks taking up about half the space, and upon these place a layer of turfy loam, and then fill in, shaking the soil moderately firm to within an inch of the top, and on the surface place the pseudo-bulb with enough soil added as will cover the base of the plant and no higher. Place in the best available position in the East Indian house or plant stove, but afford no water at the root for several weeks, merely damping between the pots each afternoon at closing time instead. When growth advances, the soil may be sprinkled lightly, for much water will cause the roots to go black at the points, and the new growths to damp off. As soon as the roots are seen around the sides of the pot, more water may be afforded by degrees. Most species of *Calanthes* are readily increased by taking off the old back bulbs, and inserting them in pots filled with sphagnum moss. The different varieties of *C. Regneri* that are now in full bloom may be repotted when growth recommences. Plants that are bearing seed-pods should be stood in a sunny position to ripen the latter. It is not necessary to cut off the capsules immediately they burst, for a piece of tissue paper tied loosely around them will prevent the escape of the seed. By the time the old flower-stems begin to die down the seed will be fully ripe. It may be sown upon the surface of the soil of the best rooted plants; and till it germinates, these plants should be afforded water with a very fine rose-can. When the seedlings are fairly rooted, the water needed by the old plants will

not harm them, but they must not be disturbed till the following spring. Last year's seedlings may be potted forthwith.

THE HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Peaches and Nectarines.—As soon as the petals fall, disbudding should be commenced, and completed in several operations at intervals of a week or ten days, according as the growth of the trees is rapid or slow. The practice of doing the disbudding at one operation causes much of the fruit to fall off, and is injurious in various directions. Trees recently planted should not be disbudded at all; on the contrary, they should be allowed to make all the growth they are capable of during the first few weeks, so as to favour the activity of the roots, the shoots not required for building up the foundation of a crown being stopped after the shoots have made 2 inches of growth. In disbudding replanted trees, the disbudding should not be severe on the first occasion it is practised; and on established trees the shoots at the back and front of the branches should be those first removed, rubbing them off with the hand, any young fruits found at the base of the shoot being left uninjured if it be thought desirable to retain them. It is a better practice to nip off the point of the shoot in this case, leaving the base of the shoot with the young fruit on it. If fruits have set thickly, the worst placed should first be thinned off, and the others left on the branches and shoots at 3 inches apart, always removing those that are small and weak. The points of shoots should for the present not be pinched, but this may be necessary with some of them later on, so as to avoid crowding, but the third disbudding is the best time to do this. If aphides appear at this stage, they commit havoc by creeping into the remains of the flowers that have set, and the best means to employ against them is to moisten the trees on a fine day with a syringe and then apply Tobacco-powder with an indiarubber distributor. Continue to make use of the coverings at nights and during cold windy days also, which is the surest preventative of mildew and blister, so injurious to the Peach-tree out of doors.

Apricots.—If fishing-nets are employed as a covering, let them be lifted on fine days in order to harden the foliage, putting them on again before nightfall, and continue to do this till the leaves are sufficiently large to protect the fruits from injury by frost.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Tubers of Dahlias.—Any of these not started for furnishing cuttings should be placed in gentle warmth, say 50° to 55° . Cuttings may still be taken and potted in leaf-mould and sharp sand, three to five in a 60, and plunged in bottom heat. Do not afford the cuttings much moisture, or a too humid air, or they will damp off. Pot these off singly when rooted, and grow in a warm house for a week or two before removing them to a lower temperature. The old roots should be potted and got into growth without undue haste.

Ornamental Ponds and Lakes.—The present-day taste favours the creation of artificial water in gardens, and very ornamental these become when properly placed and suitably planted about with flowering shrubs and trees, and flowering plants of low growth. For planting in the water itself, *Nymphaeas*, of which there are many beautiful species and varieties, are among the best to use. Varieties which can be obtained at a nominal cost, viz., *N. alba* (the white Water lily), and *Nuphar lutea* (the yellow flowered one), *Apongeton distachyon*, a very hardy plant that should not however, be planted in water that is more than 3 feet deep; for quite shallow water, or where they are just out of the water's reach, the following species should be planted, *Caltha palustris*, *Osmunda regalis*, a very beautiful plant when established; *Butomus umbellatus*, *Ranunculus varius*, *Saxifraga crassifolia*, the *Solidagos*, and *Typha latifolia*, the common Bulrush. On the banks there may be planted the hardy Bamboos, if possible in clumps, these being far more effective than isolated specimens. Of Bamboos the following species are suitable:—*B. Fortunei* variegata, height 2 feet; *B. Metake*, hardy, and a large grower; and *B. Simoni*, a rapid-growing variety. *Arundo Donax* is also a suitable plant for planting by the water-side; also the following, *Carex pendula*, *Elymus glauca*, *Glycerium argenteum*, planted either in clumps or isolated specimens there, or in other parts of the garden. *Eulalia zebrina*, the foliage barred with yellow, which has a telling effect, is excellent.

There are many other subjects beside those enumerated here, which are equally suitable to this style of planting in pleasure-gardens, which, if afforded sheltered positions, will give interest to a style of gardening which is too rarely seen.

Hints on Work in General.—The true spring-like weather that has followed the north-easterly gales of the previous week will have enabled the gardener to get a considerable amount of work done, and we may now anticipate chiefly favourable weather. The whole of East Kent was swept by a storm of wind and snow, accompanied with frost, which continued without ceasing up to Saturday, checking vegetation generally, and destroying much of the beauty of the spring-flowering garden, and loosening newly-planted trees and shrubs. These latter must have attention forthwith, and the soil made firm round the stems and over the roots. In securing trees and shrubs to posts and stakes, be sure to place a pad of hay, a bit of shoe-leather or cloth, between the bark and the latter. A good kind of tie made of straw and tarred string was figured in the *Gardeners' Chronicle* for November 24, 1883, p. 653.

THE KITCHEN GARDEN.

By J. W. MCHATTIE, Gardener, Strathfieldsaye, Hants.

Globe Artichokes.—Now that the danger from frost is at an end, the litter which was placed about the plants last autumn may be removed, partially completing the work in about a week, and then afford a liberal dressing of woodashes and rotten stable manure round each stool, covering the manure with soil so as to form small mounds; dig the land between the plants with a fork, and give a mulch of fresh stable litter. When in full growth, and especially in hot, dry weather, Artichokes are benefited by copious applications of weak liquid manure. Do not stint the seedlings raised from seed this spring of rooting space, nor keep them far from the glass, as only sturdy vigorous plants will produce a supply of large heads this season.

Transplanting Seakale roots and cuttings.—Any roots that are not required for forcing, also one-year-old seedlings, may now be planted in rows 2 feet apart, and 6 inches between the roots, covering the crowns with half an inch of soil. Cuttings which were made in the winter having calloused, may also be planted in rich land, in rows 2 feet apart, and 8 inches between the cuttings. Seakale seed may now be sown rather thickly in rows, previously soaking the seeds in water for 24 hours. The drills may be drawn 18 inches apart, and 2 inches deep, and when the seedlings are up thin them out to 6 inches apart, in moist weather. Let the supplies of blanched Seakale during this and next month be kept up in accordance with requirements. At this season forcing is readily done under Seakale pots alone, if a sufficient quantity of soil be drawn up round the base so as to perfectly exclude the light; a small quantity of clean straw or dry leaves is an assistance to the blanching, if put over the crowns.

Autumn-sown Onions.—A piece of well-manured land should be prepared, on which drills 12 inches apart and 2 inches deep should be drawn for receiving the surplus of the crop. If the Onion-bed is hard, or the weather dry, afford it water, in order the better to extract the roots when drawing the plants; and having drawn a number where they stand thickly together, plant each separately with a long dibber, covering the fibrous roots, but not the bulb itself, and make the soil very firm about the roots.

General Work.—Let sticks be placed to Peas on their appearance above ground. Thin the rows of Spinach more or less according to the strength of the variety; also Turnips and Radishes, sprinkling fresh soot along the rows of those vegetables as a deterrent to birds and slugs. Red Dutch Cabbage may be planted in rich soil at 2 feet apart; and remove the remainder of crops of winter vegetables that are of no further use. Ply the draw and the Dutch-hoes freely in all parts of the garden, in order to kill weeds, and aerate the soil.

TRADE NOTICE.

THE Station Nurseries, Horsham, carried on by Mr. J. G. Jenner for the past twenty-five years, have been purchased by Mr. Riley Scott, who was for upwards of twenty-three years steward and head gardener to Miss Foster, The Holme, Regent's Park, London, and Oakover, Ticehurst, Sussex.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR APRIL.

WEDNESDAY, APRIL 6	{ Royal Caledonian Horticultural Society's Exhibition (2 days).
THURSDAY, APRIL 7	{ Linnean Society Meeting. Royal Horticultural Society of Ireland (Exhibition).
SATURDAY, APRIL 9	—Royal Botanic Society Meeting.
MONDAY, APRIL 11	—Bank Holiday.
TUESDAY, APRIL 12	{ Royal Horticultural Society's Committee's Meeting.
SATURDAY, APRIL 16	{ Ghent Quinquennial Horticultural Exhibition, open until 24th inst.
WEDNESDAY, APRIL 20	{ York Florists' Spring Exhibition. Durham, Northumberland, and Newcastle Horticultural Society's Spring Exhibition (2 days).
THURSDAY, APRIL 21	—Linnean Society Meeting.
SATURDAY, APRIL 23	{ Royal Botanic Society, General Meeting.
TUESDAY, APRIL 26	{ Royal Horticultural Society's Committee's Meeting.

SALES FOR THE ENSUING WEEK.

MONDAY, APRIL 4	{ Roses, Hardy Perennials, Cannas, Iris, &c., at Protheroe & Morris' Rooms.
TUESDAY, APRIL 5	{ Imported and Established Orchids, at Protheroe & Morris' Rooms.
WEDNESDAY, APRIL 6	{ Japanese Lilies, Carnations, Roses, Decorative Plants, Palms, &c., at Protheroe & Morris' Rooms. Palms from Ghent, Shrubs, Roses, Plants, Bulbs, &c., at Stevens' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—46.7°.

ACTUAL TEMPERATURES:—

LONDON.—March 30 (6 P.M.): Max., 55°; Min., 37°.

PROVINCES.—March 30 (6 P.M.): Max., 46°, Scilly; Min., 39°, Aberdeen.

Variable; rain, sleet, wind, becoming brighter and more settled.

Carnation Disease.

We very frequently receive leaves of Carnations marked with small translucent spots, and presenting the characters of leaves supposed, with more or less truth, to be due to bacteria. Some of our experts, to whom such leaves have been transmitted, have considered the spots to be the initial stage of some fungus. Dr. ARTHUR, in a paper originally read before the American Association for the Advancement of Science, 1889, came to the conclusion that the disease is caused by "parasitic bacteria entering the plant from the air through the stomata, or occasionally through the punctures of aphides."

The name Bacteriosis has accordingly been given to this disease, but more recent researches render it doubtful if the bacteria have anything to do with it. Mr. ALBERT WOODS, Assistant-Chief in the Division of Vegetable Physiology and Pathology at the United States Department of Agriculture at Washington has re-investigated the matter, and has published the results of his labours in the *Centralblatt für Bakteriologie, Parasitenkunde, und Infektionskrankheiten*, 111 Band, 1897. He tells us his method of research, which it would be tedious to describe here, and which can only be carried

out in a properly-equipped laboratory. The general result is, that the appearances in question are due to the attacks of aphides or thrips, and that the bacteria, if present at all, are not the causes of the disease. It is, however, better to give the author's conclusions in his own words:—

Summarising, it may be said that:—

1. The disease of Carnations characterised by the symptoms already described and generally known as "bacteriosis," is wide-spread and destructive.

trouble, is shown by the fact that the injuries produced are not accompanied in the earlier stages by fungi or bacteria. The aphides, therefore, cannot be looked upon simply as carriers of some fungus or germ.*

7. Injuries similar in many respects to those produced by aphides, also result from the attacks of thrips, an insect nearly always present on Carnations under glass, although generally overlooked by growers.

8. The Carnation is a plant readily influenced by the conditions under which it is grown, and as a result the reaction to the injuries of the aphides, and

FIG. 76.—EULOPHIELLA PEETERSIANA: SHOWING HABIT. (SEE P. 201.)

2. In the earlier stages of the disease neither fungi nor bacteria are present, so far as can be determined by the most careful microscopic studies and bacteriological investigations.

3. As the disease advances, various organisms may appear, but their presence is not constant.

4. Infection experiments with such organisms, carried on under rigid bacteriological conditions, resulted negatively in every case.

5. A disease having all the characteristic symptoms of "bacteriosis," excepting the presence of a bacterium, is produced by the puncture of aphides, as was repeatedly proved by the colonisation of these insects on the plants.

6. That the aphides alone are responsible for the

the susceptibility to their attacks, not only vary with varieties, but with individuals of the same variety. Plants, therefore, grown under improper conditions will show more of the characteristic injuries from a given number of aphid punctures than those where all the conditions have been favourable for growth.

9. Proper selection and propagation of stock, furnishing soil, moisture, light, and air best adapted to healthy and vigorous growth, and keeping down to a minimum the number of aphides and thrips, will enable the grower to successfully combat the disease." August 15, 1897.

EULOPHIELLA PEETERSIANA, FLOWERING FOR THE FIRST TIME IN EUROPE IN THE GARDEN OF SIR TREVOR LAWRENCE, BART.

(Portion of flower-spike, natural size. Flowers deep bright purple; lip white, blotched with purple. See p. 201.)

EULOPHIELLA PEETERSIANA (Supplementary woodcut).—Under this name, Dr. KRÄNZLIN, of Berlin, described a highly remarkable Orchid in our columns, March 20, 1897, p. 182; and now, a twelvemonth later, we have the satisfaction of publishing a representation of the flowers. It is to Sir TREVOR LAWRENCE, Bart., that we owe this privilege, and whilst thanking him we may also congratulate him on his success, and pass a compliment to his Orchid grower, Mr. WHITE. The stem, in Sir TREVOR's plant, curves and twines among the branches of trees like a snake, but does not show the very large fusiform bulb described by Dr. KRÄNZLIN. The leaves are from 2 feet 5 inches to 3 feet 10 inches in length. The racemose flowers are borne on a scape, which grows more than a yard in height before the flowers are produced. Each flower measures about $3\frac{1}{2}$ inches across, the sepals being bright purple with a very intense purple blotch at the tips; the petals are purple, not blotched. The lip is white with a broad purple outer border, with four erect vertical crests. The throat is white streaked with orange. Mr. WORTHINGTON SMITH's drawing will furnish the details required by the grower; whilst for the botanical characteristics, the reader is referred to Dr. KRÄNZLIN's description above cited.

LINNEAN SOCIETY.—On the occasion of the evening meeting, Thursday, April 7, 1898, at 8 P.M., the following papers will be read:—I. "On the Brain of the Edentata, including Chlamydopterus," by Dr. ELLIOTT SMITH; and II. "Preliminary Account of some New Zealand Actinaria," by Mr. H. FARQUHAR.

THE ROYAL GARDENERS' ORPHAN FUND.—We are reminded that the Annual Festival Dinner of this most deserving charity will take place on Wednesday, April 20, at the Hôtel Métropole, under the presidency of C. E. KEYSER, Esq., of Aldermaston Court, Reading, and late of Stanmore. Mr. KEYSER is so well known as a patron of horticulture, that we hope there will be a large number of gardeners present to give Mr. KEYSER a cordial reception.

FOR THE GARDENERS' ORPHAN FUND.—At a meeting of the committee, held on the 25th ult., amongst the donations announced was a handsome gold engagement-ring from a "Lover of flowers," with a request "that it be sold for the benefit of the Fund." Here is an opportunity for some enterprising youth!

APOGAMY, AND THE DEVELOPMENT OF SPORANGIA UPON FERN PROTHALLI.—On March 3, Mr. W. K. LANG communicated to the Royal Society a paper on "Apogamy, and the Development of Sporangia upon Fern prothalli," detailing the results obtained from a series of cultures of ten species of Ferns, the prothalli of which were grown for more than two years. The conditions of cultivation differed from those under which prothalli usually occur in nature, in that fertilisation was prevented by avoiding watering from above; the prothalli were also exposed to direct sunlight. To these causes the results, which in the main agree for the various species, may be ascribed. The most important were the change in form and structure of the prothallus to a fleshy cylindrical process, which sometimes proceeded from the apical region, sometimes from the under-surface just behind the latter; the development of conical projections around or in place of archegonia, and the occurrence of more or less numerous cases of apogamy in every one of the species. The latter phenomenon was manifested by the presence of tracheides in the tissue of the prothallus, by the development of isolated members of the sporophyte upon it, and in every case but one, of complete vegetative buds. On prothalli of *Scolopendrium vulgare* and *Nephrodium dilatatum*, sporangia, which sometimes attained almost perfect development, were found. In conclusion, the bearing of the results on the nature of the alternation of generations seen in archegoniate plants is considered, and a provisional hypothesis is suggested to explain how the definite alternation of sexual and asexual forms might have originated by modification of individuals of the ancestral algal organisms under the conditions to which they would presumably have

been exposed on their assumption of a terrestrial mode of life. *Nature*, March 24.

"THE HOUSE."—The magazine known as *The House*, and described as being an "artistic monthly for the home," continues to keep up the interest which the appearance of its first number called forth. In addition to such housewifely subjects as furniture and artistic needlework, the magazine deals also with what are known as "home arts." Prominent among these is "Tarsia," a simple form of marquetry executed in natural woods, and worth mention as being novel in idea and satisfactory in execution.

TAR-WATER FOR LEAF-MINERS.—Mr. KIRK, whose death we had recently to deplore, reported in the New Zealand Biologists' Report that tar-water is an excellent remedy for the grubs of a fly which disfigures the leaves of Cinerarias, Chrysanthemums, Marguerites, &c. To prepare the tar-water, boil half a gallon of coal-tar in one gallon of water, let it stand to cool, and dilute with fifty gallons of water. The tar-water is lightly sprayed in fine spray over the leaves. The glass and stages of the house may also be sprayed.

"DIJON VITICOLE AND HORTICOLE."—Under this title we have received, in one pamphlet, the first and second numbers of a new publication, edited by Mr. T. VUILLERMET. It is intended to be a popular illustrated magazine of horticulture and Vine-culture, the specimens before us including papers on such subjects as, remedies for black-rot, street-planting of fruit-trees, good varieties of Potato, &c. The beginning is satisfactory, so we will hope that deserved success will ensue.

ENGELMANN CAÑON, COLORADO.—*Meehan's Monthly* for March gives the following account of the origin of a name. We there read that: "Frequent occasions have been taken to point out how unreliable are a large portion of statements that go on record as the 'truths of history.'" Even in our own times, statements are given for facts which those living can controvert. Just before us, for the first time, appears a pamphlet by CHARLES A. WHITE, entitled *Memoir of Geo. Engelmann*. On p. 19 we read, "Dr. PARRY, like other friends of Dr. ENGELMANN, delighted to do him honour. While engaged in his earlier explorations, he gave Dr. ENGELMANN's name to the picturesque cañon through which now passes the cogwheel railroad from Maniton to the summit of Pike's Peak, in Colorado." It so happens that Dr. PARRY knew nothing of this cañon, nor did any other man up to 1871. It was marked on all the maps as the "Unknown Cañon." The first man to surmount the difficulties of its exploration was Prof. THOMAS MEEHAN, who alone succeeded in getting through. Complimented by the surveyors, he was told by General CAMERON, the head of the surveying party, that by virtue of being the original explorer he might give a name to the cañon. On this suggestion the "Unknown" was erased from the map, and "Engelmann" substituted. Dr. ENGELMANN's name occurred to Mr. MEEHAN from the beautiful specimens of *Abies concolor*, a species which prevailed there—and Dr. ENGELMANN's labours on the Coniferæ naturally suggested it.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held in the Lord Mayor's Parlour, at the Town Hall, Manchester, on Wednesday, April 20, 1898, commencing at 11 A.M., when several papers will be read and discussed. Members intending to take part in the visit to Manchester, or to attend the dinner, or one of the excursions, should, if they have not done so, return the fly-leaf of the Circular already sent to them not later than April 13, and as much earlier as possible. Special dining-car carriages will be attached to the 5.30 P.M. train leaving the Great Northern Station, King's Cross, on the evening of Tuesday, April 19, in which seats will be retained for those members who intimate to the Secretary, before that date, their intention of dining *en route*. Notice is given that the Institution will be closed from Thursday evening, April 7, to Wednesday morning, April 13.

RATING OF GLASS-HOUSES: *Smith and Others v. Richmond*.—We are glad to learn that the Market-Gardeners', Nurserymen, and Farmers' Association—who, it will be remembered, successfully fought out the case of Purser v. Worthing Local Board—are moving in this important case on behalf of the trade, with a view to an appeal to the House of Lords.

CAPE FRUIT.—The ship *Gascon* of the Union line has brought over 298 boxes of Grapes, consigned to Mr. HUDSON. The whole being described to us as "wet," and the reason given for this condition is that the fruit was gathered during rainy weather and packed in a damp state. It is a pity that this should have been allowed, and would appear to indicate either little commercial ability or common sense in the exporter.

WRECK OF THE "CHINA" STEAMSHIP.—Whilst our last week's issue was being printed, in which it was announced that the P. and O.'s ship *China*, from Australia, was *en route*, and due here on the 11th inst., that ship had got on the rocks at Perim Island, and it was announced in the daily press that she was likely to become a total wreck. The P. and O. Company has surely the sympathy of our readers, so enterprising have they been in the far East and at the Antipodes; and as fruit carriers their ships had obtained distinction for the excellent condition in which the fruit cargoes entrusted to them were delivered. The *China* had on board some 16,000 boxes of Apples, &c., from Tasmania and other Australian ports, and it is not supposed to be likely that any of these can be salvaged, and the owners of the vessel express similar fears. Whether the shippers will venture to make good the loss may to some extent depend on the brokers here, and on the demands at home. However that may be, the general expressions of regret show how much Tasmanian Apples have become home necessities.

THE MILD WINTER AT TORQUAY.—The high mean temperature during the two autumn months, October and November, of 1897, and during the winter of months December, January, and February last, was quite extraordinary. The mean temperature of each of these months, and the excess or accumulation of heat degrees above the average of twenty-two years during this period are:—

October, 1897, the mean temperature was 54.2°, or 3.1° above the average of 22 years.

November, 1897, the mean temperature was 49.4°, or 2.3° above the average of 22 years.

December, 1897, the mean temperature was 46°, or 3.1° above the average of 22 years.

January, 1898, the mean temperature was 47.1°, or 5.6° above the average of 22 years.

February, 1898, the mean temperature was 44.1°, or 0.7° above the average of 22 years.

The mean temperature of the five months was 48.2°, or 14.8° of accumulated heat degrees above the average of 22 years' observations at Torquay.

Western Morning News, March 16.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—A special meeting of members of this Association, which was largely attended, was held in the Abbey Hall, Reading, on Monday evening, to help forward the objects of the Gardeners' Royal Benevolent Institution. Mr. HARRY J. VEITCH and Mr. GEORGE J. INGRAM attended at the invitation of Mr. ARTHUR W. SUTTON, and addressed the meeting, explaining the objects and the working of this truly admirable Institution. The chair was taken by the President, Mr. CHARLES B. STEVENS.

GERMANY.

WILHELMSHÖHE.

No one visiting North Germany should miss the opportunity of visiting Wilhelmsöhe, near Cassel. It is one of the most beautiful spots in Germany, and one that appeals very much to an English eye, with its fine park, and large open lawns. Above all,

however, when one has the good fortune to be able to time one's visit for a day when the cascades roll down the mountain side, and the fountains are playing, it is beautiful indeed.

Since the year 1866, when Cassel and Hanover lost their independence and were united to Prussia, it has been a summer residence of the German emperors, and was assigned to the captured Emperor, Napoleon III., in 1870 after the surrender at Sedan, with its rather dull old castle as domicile, until about the end of the war in 1871, when he came over to Chislehurst, where he died a few years later.

What I should, however, most especially like to draw attention to at Wilhelmshöhe, is the bedding in front of the castle, which is most beautiful, a dwarf variety of Begonia, of a most lovely rosy pink called Beg. Bavaria being very extensively used, and giving the whole a charm seldom seen. I should very much like to say at a later date a few words more about this pretty Begonia. Then the collection of Darlingtonias and Sarracenias, in the conservatories, although not to everyone's taste, and many other old half-forgotten favourites, are very interesting. In the absence of Herr Hofgärtner Fintelmann, who was away at Homburg, decorating on account of the presence of the Imperial and Royal personages at the manoeuvres near Frankfurt-on-Maine and Homburg, I had the pleasure of being shown round by the Chief-Assistant, Mr. Paul Böhme, and was really surprised at the beauty of the double tuberous Begonias cultivated in pots here. I must admit that they were equal to the strains cultivated by Mr. Wilh. Pfister in Stuttgart, who is generally considered to be the best grower and hybridiser of these plants in Germany.

Another beautiful old favourite, which however, in these days of hurry and worry, is too slow in growth and propagation for most people, is *Witsenia corymbosa* (syn. *Nivenia stylosa*), a native of the Cape of Good Hope. It has, from a distance, the appearance of being a dwarf Palm, after the manner of the *Chamærops humilis*, and produces a great number of small star-like flowers of a lovely azure-blue. It is seldom without a few flowers; its main flowering period is, however, during the later summer months, until late into the autumn, during which period it is simply covered with its small but beautiful flowers.

What one misses at Wilhelmshöhe, where such ample opportunity is afforded for displaying their many beauties, are the newer dwarf and large-large-flowering Cannas. I only saw one or two old-fashioned, closely-planted groups of the rather ancient small-flowering varieties, with large foliage. As a lover of Cannas, I should have liked to have seen them done more justice to here.

Planted out in lawns singly, or in parties of ten, twenty, or more, as the position and circumstances prescribe, but in such a way that each plant has plenty of room to develop and show its own peculiar beauties, the effect produced is much more artistic and beautiful than when huddled together in a mass as is here the case. Perhaps another time we may find them better represented, especially as there are among the novelties of the last few years several sorts which will stand almost any weather, rain or heat, and yet look smiling. And I think we may hope for more improvement in this respect. In Stuttgart, the Canna city of Germany, especially, much care and attention is given to their hybridisation and selection on these lines, as well as in the size of their flowers and pureness of colour. However, to turn back to Wilhelmshöhe, my closing remark is, "Do not omit to visit it another time, for it is a place worth going a few miles out of one's way to see." *H. R. W., Stuttgart.*

ST. ANNE'S, CLONTARF, Co. DUBLIN.

THIS seat of Lord Ardilaun is beautifully situated just outside Dublin, and commands beautiful views of the lovely bay. The electric-tram takes you almost to the lodge-gates. When once within the park, there are signs of a well-kept estate; the drives are good, there are grand trees, and everything is in neat order. Passing up the drive I noticed

the stables, a splendid pile in red brick. A little farther on, the mansion appeared, and at first sight it does not strike one as very imposing; but on closer inspection it proved to be a splendidly-built house of Portland-stone. On this side it is surrounded by broad stretches of turf dotted here and there with groups of fine trees, underneath which are planted thousands upon thousands of Snowdrops, Crocus, Tulips, and Narcissus of all the better, as well as the common kinds.

Passing on to the left, I was soon in the enclosed garden, at the entrance to which I noticed a house, that I was informed was once the gardener's residence, but is now occupied by the young men, by his lordship's orders, and splendidly they are housed.

In the glasshouses there is at once evidence of good cultivation in a fine batch of white Cyclamen, carrying hundreds of blooms; and on the other side of this house was a batch of *Freesia refracta alba* just coming into flower, and smothered with strong erect flower-spikes. These, and Violets and Carnations, are favourites of her ladyship's, and are therefore grown in quantity. I next noticed a large house formerly used as an orangery, but now used for the growth of tropical plants. The fine Palms, Ferns, &c., interspersed with rockwork and winding stone paths, are very effective. I saw a few of the old Orange-trees cut back and tubbed; but I was more interested in two very fine clumps of *Papyrus antiquorum*. Never having previously seen this plant, its value in winter gardens, &c., with its Cyperus-like heads, carried up to a height of from 10 to 20 feet, greatly impressed me. It is also very useful in a cut state for large vases.

There were great quantities of Violets in pots, all of them first-rate plants in capital health. Mr. Campbell, the gardener, has evidently found out what they require, and gives it to them.

Tea Roses, Carnations, Primulas, &c., Orchids, including some of the rarer varieties, all appeared healthy and well cultivated. In a range of vineries some good Colmar Grapes were still hanging.

I next noticed a very pretty grotto fernery, and a very fine piece of the Killarney Fern (now becoming very rare in Ireland), which was gathered by Mr. Campbell himself.

There are two kitchen gardens, and this one near the house is devoted largely to the growth of Carnations, herbaceous, and alpine plants. On the outer walls were Ivies, Jasmines, Forsythias, Garrya, and here and elsewhere very fine trees of the beautifully-scented *Chimonanthus*, or *Calycanthus fragrans*, literally smothered with flowers. The other garden, $1\frac{1}{2}$ mile away, provides the fruit and vegetables.

We next visited the Glen, a most picturesque feature, extending nearly the whole length of the grounds, now made very fine with rockwork, ornamental water, &c., and a stream traverses the whole length. At one time, Mr. Campbell informed me, the tide came quite up to this spot. Every bank or nook is occupied by some interesting plant or bulb, and seen even in the winter it was an agreeable sight. Passing down the Glen, one sees a very fine avenue of Evergreen Oak, the favourite tree of Lord Ardilaun, and therefore grown and planted all over the estate in thousands.

We next visited a summer or tea-house, overlooking a beautiful piece of water, in and around which grow choice aquatics and bog-plants.

The rock and alpine gardens near the house are sheltered by very fine Yew hedges. These plants had just been re-arranged, replanted, and re-labelled. Here was a grand bed of the scented Lippia (*Aloysia citriodora*); the plants were 5 or 6 feet high, and quite hardy. Also grand clumps of hybrid Anemones, of which Mr. Campbell has been so successful a raiser.

There is a fine Rose-house near the house; also a large conservatory, in which were two very fine *Dicksonias*, the side stages in this house being hidden by an invention of her ladyship's, in which was planted *Selaginella*.

I understood Mr. Campbell to say that in the centre of the mansion there is a winter-garden filled with Palms, &c., the effect of which from the various rooms is grand. *F. H.*

TREES AND SHRUBS.

A DANGEROUS DISEASE OF THE WEYMOUTH PINE.

THE Weymouth Pine (*Pinus strobus*), though a useful timber-tree, is in this country most appreciated for the pleasant variation its graceful form and foliage give to our parks and other collections of trees. Unfortunately, reports are becoming frequent of a disease fatal to the beauty, if not to the very existence, of this useful Pine. It is the more necessary to direct attention to this, because the disease is clearly being distributed from a part of Germany whence we import nursery-stock. The disease has made itself evident over the greater part of Germany, Denmark, &c., but in the north-east of Germany it has assumed the nature of an epidemic. A park in Bremen is reported on good authority to have 30 per cent. of the Weymouth Pines more or less destroyed; in a large nursery in Westphalia near the Dutch frontier the epidemic became so severe that the stock was destroyed, and this Pine for the present is left out of cultivation; round Hamburg the disease is common in many nurseries; and a supply of Weymouth Pines, taken from a nursery in Holstein to replenish a forest near Lake Constance, had to be removed and burned in less than two years.

The disease is caused by a rust (*Peridermium strobi*), allied to a well-known rust (*P. pini*) on Scots Pine and other Pines; it is, however, a distinct species, as far as we know not contagious to any of our common Pines. The symptoms consist of a swelling on twigs or branches, frequently just under a branch-whorl. The swelling soon becomes the seat of a crop of very distinct blister-like out-growths, with a yellowish to golden colour; these are the spore-producing organs of the fungus, which has long ere this established itself in and under the bark, so that in course of time the twigs dry up, the needles drop off, and no new growth follows. Fortunately, the spores produced are not able to directly attack other Weymouth Pines, for, like many of its allies, the fungus requires a sojourn in a new plant in order to complete its life-history. This new host is found in Black Currant, Gooseberry, and other species of *Ribes*. The fungus is also dangerous to the fruit-bushes, but cannot yet be called an epidemic. It attacks leaves only, appearing in June as a yellow rusty coating, which is followed by a number of brown hair-like out-growths. This is the fungus-form known as *Cronartium ribicolum*. The Weymouth Pines become infected from the Currant-bushes, hence, probably, the reason why nurseries have become the sources of distributing the diseased trees.

Neither of the forms of the rust are common in this country—in fact, as far as we know, they are rare; nor is the Weymouth Pine attacked by this disease in North America, its native country. Destruction of diseased material is the only reliable remedy as yet. If, however, those desirous of planting are careful in selecting a healthy source, we need never in this country be serious losers by either the Weymouth Pine or the Currant-disease. In case of doubt as to diseased specimens, these might be forwarded to the Editor of the *Gardeners' Chronicle*. *William G. Smith, Yorkshire College, Leeds.*

AMERICAN NOTES.

NOVA SCOTIA APPLES.

PRESIDENT J. W. BIGELOW, of the Nova Scotia Fruit Growers' Association, in his annual address, spoke of the unusually short crop of Apples in 1897, and compared it with the production in previous years. He gave the following figures as representing the annual exports to London since 1890:—

1890, shipped ...	53,267 barrels.
1891 " " " "	89,199 "
1892 " " " "	116,725 "
1893 " " " "	35,058 "
1894 " " " "	254,410 "
1895 " " " "	155,955 "
1896 " " " "	409,473 "
1897 " " " "	85,000 "

These figures he estimates to represent about two thirds of the entire Apple-crop of Nova Scotia.

PREVENTION OF GOOSEBERRY MILDEW.

The English varieties of Gooseberries are hardly ever grown in America, on account of their extreme liability to the attacks of mildew. In their place numerous varieties, derived from indigenous American species, have been substituted. There is, however, a constant endeavour to grow the English varieties; and in this work the repression of the mildew is the chief problem. Native varieties are also sometimes attacked, so that there is always a lively interest in every new bit of information

potassium sulphide, the best solution costs about one-fifth of 1 cent for each plant treated seven times.

"GARDEN MAKING."

This is the title of Professor Bailey's latest book, now just fresh from the Macmillan Company's press. It is a handy manual of 411 pages, with an excellent index. It is lavishly illustrated, and well printed, excepting a few oversights on the part of the proof-reader. The general plan of the work seems to be to give "suggestions for the utilising of home-

Garden-making comes in the *Garden Craft* series, which already includes the Rule Book, the Nursery Book, Plant Breeding, the Forcing Book, and for which the Pruning Book will soon be ready. The series, as a whole presents a very convenient set of hand-books, easy of reference, and infinitely useful to any one who has not already learned everything there is to know.

NOTES ON SOME AMERICAN SPECIES OF PRUNUS.

Hitherto, I have spoken in these columns of the richness of our native Plum flora in America. The following native species have been considered worthy of some degree of cultivation:—*P. americana*, *P. americana nigra* (*P. nigra*, Ait.), *P. angustifolia* (*P. Chicasa*, Michx.), *P. hortulana*, *P. alleghaniensis*, *P. subcordata*, *P. umbellata*, *P. maritima*, *P. Watsoni*, *P. gracilis*, and possibly *P. rivularis*. Besides these we have several groups of native hybrids like the Miner group of *P. hortulana*. In fact, Professor Bailey, who created the species *P. hortulana*, has more recently decided that they are all hybrids of *P. americana* and *P. angustifolia*, and this view seems likely to be generally accepted.

Botanists have had some trouble in reaching an agreement as to the standing of Aiton's *P. nigra*. Torrey and Gray consolidated it with Marshall's *P. americana*—a step fully justified by Marshall's original description. Bailey has followed this plan. Sargent, on the other hand, in *Sylva of North America*, regards these as two distinct species, and uses Aiton's name, *P. nigra*. For reasons fully set forth elsewhere, I have thought it best to make *P. nigra* a botanical variety of Marshall's species, and have called it *P. americana nigra*. The species *P. Watsoni*, erected by Sargent in 1892, has recently been the subject of special study on my part. It constitutes a very interesting group of western dwarf Plums, growing mostly on sand dunes along river banks. It is very difficult to distinguish this species from *P. angustifolia*, and it is quite possible that we may have to recombine the two. *P. rivularis* was erected by Scheele (Germany) from specimens collected in south-west Texas; but from the meagre evidence now at hand, I somewhat doubt the existence of any such species. The specimens collected by Lindheimer, and made the foundation of *P. rivularis* by Scheele, may very possibly have been some hybrid offshoot or vagary of the *hortulana* group, for such anomalous forms are found all through the lower Mississippi valley. *F. A. Waugh.*

HOME CORRESPONDENCE.

PLANTS UNDER TREES OR NATURALISATION.—

This topic is often ventilated but rather inadequately and differing as to choice of subjects, and as a rule I see small evergreens recommended. I have tried effects for years, but have never found anything to rival *Convallaria Polygonatum* (Solomon's Seal), the graceful arches of this plant, 1½ to 2½ feet high, enhanced at time of flowering by its pretty although small bells, is unique—in such spots—from the extraordinary effective aspect, an effect intensified by the extreme contrast to everything else possessed by this plant, which under almost all other surroundings falls comparatively flat on observers. Of course it should be naturalised, and two or three dozen or more of these handsome arches form a more or less compact mass in three or more different irregularly-formed stations under some large tree, with less number under smaller trees. If placed on masses of low rooteries, with the roots facing the spectator, and partly Ivy-covered, with the central parts filled in with soil, to form stations for Solomon's Seal, the effect is superb. The plant, if grown in the shade, cannot be killed by neglect in watering in such a situation, and its strong tubers may rather require thinning in years to come. I should like to see this plant covering stretches in woodland in the midst of the brown-tinted fallen Beech-leaves, being yet another contrast of colour. In a like position another most charming effect would be produced by the Oak Fern, *Polypodium Dryopteris*, some oasis of which in the browned leaves have a charming effect. If this be joined in similar naturalised style by the one finer variety of *Equisetum* (Horsetail), I am convinced that few pictures would be more delightful in naturalisation. Going further afield, without however moving outside the strictly appropriate, we have for a

FIG. 77.—DENDROBIUM NOBILE ASHWORTHIANUM.

(A pure albino shown by E. Ashworth, Esq., at the meeting of the Royal Horticultural Society on March 22, 1898. (See our Report in the issue for March 26.)

touching the treatment of this malady. Long continued experiments at Geneva, New York, indicate the superiority of potassium sulphide for this purpose. It is dissolved in water at the rate of 1 oz. to 2 or 3 gallons, and applied to the bushes early with a spray pump. Bushes thus sprayed with the potassium sulphide solution showed 5 per cent. of mildewed fruit; those similarly treated with Bordeaux Mixture showed 37.4 per cent.; while untreated plants showed 57.7 to 78.7 per cent. of the fruit damaged by mildew. At 18 cents a pound for

grounds," whether for ornamental or purely useful ends. There are chapters on fruit-growing and on vegetable gardening, giving advice for carrying on such work in a small way; but the author's best energy is plainly given to that part which deals with the ornamental treatment of the home-grounds. On this subject he has many happy and pungent suggestions to offer, so that it is hardly unfair to characterise the book as a pleasant text for the amateur landscape-gardener, for the man who attends his own farmyard, or city lot, or suburban place,

superior effect *Cyclamen hederæfolium album* (avoid rubrum) with its marvellous picture-foliage which would also look well in the green turf under trees. Another most chaste treasure, perhaps the extreme perfection in elegant simplicity of beauty in plants, is *Trillium grandiflorum*, a form of milky-white tint, not excelled by any other flower whatever. One or more dozen roots of this should be planted six inches apart in irregular clusters, when in a few years time, the most lovely mass will attract its owner daily to the spot while in flower in April and May. All formality and regularity must be eschewed in arranging these plants, so as to produce a natural effect. The low-growing, remarkably-coloured foliage of *Erythronium* (Dog's-tooth Violet), with its neatly-formed flowers of various tints (rose or flesh and lilac predominating, with one yellow), would be another acquisition in half-shade near the edge of the wood or tree with morning sun, and should be planted promptly on lifting in September. No less pleasing is the *Dodecatheon integrifolium*, and other darkest varieties, with its coquettish, miniature, *Cyclamen*-like bloom, in clusters 6 inches high, as the prettiest possible innovation. Towards the yet more sunny verges of wood and copse, the naturalisation of *Anemone appennina*, especially the blue but also the white variety of the former, are equally opportune, with the well-known *Hepaticas* in three tints, rose, blue, and white, to be planted in wide clusters, in separate colours, the large blue variety (*angulosa*) being especially effective. *Hyacinthus botryoides*, blue, and also the white variety, would be equally gems, planted in profusion, and are very cheap. A little later in flower are several rose-coloured varieties of *Oxalis*, keeping in bloom for months. A departure in habit, but a distinct success in outskirts of woods, both sunny and shady, is the beautiful *Tropæolum speciosum*, to be allowed to trail its light tendrils on any shrubs or low trees. *Scilla sibirica* in quantity, planted near and among Primroses and Snowdrops would in such situations be the earliest appropriate harbingers of spring. All these plants are eminently adapted for naturalisation, and better by far than most others so-called, but without any real attributes. In all such attempts at naturalisation, planting singly or in pairs should be strictly avoided, as the aim should be to provide irregular clusters of 1 to 3 feet across or larger, in accordance with the environment. Nobody ever objects to Lily of the Valley morning, noon, and night, and certainly masses of it would be delightful in such surroundings as above described. In all further appropriate places I should accumulate Honeysuckle. *H. H. R., Forest Hill.*

ROYAL GEORGE APPLE.—Reading the various notes that have appeared in the columns of the *Gardeners' Chronicle* recently respecting this little-known though old Apple, I was induced to look up the work of that esteemed old pomologist, the late John Rogers, of Red Lodge Nursery, Southampton, published in 1834, entitled the *Fruit Cultivator*. In that I found, amidst a wealth of reference to other Apples, the statement that "Royal George was of Irish extraction, coming into season from November to February. It was introduced into England by Sir Evan Nepean, and was propagated by the author, who succeeded in getting fruits the third year from grafting." He describes the fruits as "above middle size, somewhat flattened at each end, stalk short, eye large and prominent, general colour light yellow, dashed with red. The flesh is firm, and full of juice of a peculiar rich flavour, and may be used as dessert or kitchen. The tree resembles the Ribston Pippin in habit, but of more vigorous growth. It is an orchard tree of the first class, and well worth cultivation." This is the testimony of a man who, then of great age, had been a cultivator of fruits for fifty years, so that his statement merits the highest respect. Perhaps Clarke's Seedling, alleged to be synonymous with Royal George, is but a natural seedling from it, and possibly a reproduction. Kirke's Scarlet Admirable is described by Rogers as not a first-rate bearer. Now, Gascoyne's Scarlet Seedling is a great bearer, and, so far as my recollection goes, is a much deeper-coloured fruit than Scarlet Admirable. I had rather regarded the latter and the rich-coloured Hollandbury as very much alike. However, both are practically displaced now by free bearers. *A. D.*

CAROLINE TESTOUT, AND OTHER ROSES.—The Rev. Dr. Williamson in his notice of Garden Roses in a recent issue of the *Gardeners' Chronicle* falls into what I regard as a popular error in describing Caroline Testout as a "variation" of La France. That it is a Rose of the same type I do not contest, but I feel

sure it should be regarded as what, for want of a better term, may be called a "direct" hybrid, i.e. a seedling from a Tea impregnated with the pollen of some H.P. [!] There are in existence, I believe, three undoubted variations, not counting the climbing form, viz. Duchess of Albany, Augustine Guinoisseau, and Madame Angélique Veysset (worthless); but Denmark, I think, should be placed in the same category as Caroline Testout. "The verdict of the Royal Horticultural Society" respecting these Roses is undoubtedly a correct one. It would be interesting to know the true origin of La France, but that probably will remain for ever in obscurity. Can anyone point to a veritable seedling from this Rose? I believe it has been stated that it is the mother of Mrs. W. J. Grant, and if the Messrs. Dickson state that it is so, I for one will not question the assertion. A fact worth recording, perhaps, about Caroline Testout is, that in Australia it sets and matures naturally heavy crops of hips, whereas La France has none; it is also the grandest pink Rose in cultivation there, though we are promised shortly a novelty to supersede it. Deductions from analogy are apt to be very misleading. My father once sent me to Sydney a seedling from Baroness Rothschild × Mme. Berard, which was, to all intents and purposes, a dwarf-growing form of the latter, and when in Australia I raised a seedling from President × Village Maid, which had nothing in the appearance of wood, foliage, growth, or thorn to distinguish it from a true Gallica, and it flowered only once a year; the petals, however, were not striped. My experience of Penzance Briars is limited; but what struck me most in the few I had to deal with was the predominance of the female influence, due, I suppose, to the conditions under which the seed-bearing plants were grown; or is it that the male influence is not very potent on the Sweet Briar? To those who merely buy, propagate, or grow Roses, these details may be considered as quite unimportant; but to the few who attempt to raise new varieties by cross-fertilisation, they may be worth considering. That Madame Charles has superseded Madame Falcot in this country will, I expect, be called in question by many; it has undoubtedly done so in Australia, but though sent out more than thirty years ago, I doubt if it is so generally known or esteemed here as Madame Falcot, which is not a great deal older. *C. Bennett, Surbiton, March 21.*

SPARROWS AND CROCUSES.—The ways of that little depredator the sparrow are unaccountable, and it requires Mr. Grant Allen, who seems to understand all that passes in the minds of birds and insects, to explain them. I quite agree with Dr. Bonavia in mourning over the losses he has sustained with his Crocuses. I grow, considering my garden is small, a large quantity of yellow Crocus; for years I had to deplore the utter destruction of my blooms. It seemed to be a source of much enjoyment to the sparrow to pick them to pieces and leave the petals on the ground, for they did not seem to eat any, and I could only attribute this destruction to wanton mischief; but strange to say, for the last few years they have left them quite alone. I fed them during the few severe winters we have had, and perhaps it was gratitude [gratitude in a sparrow!] that induced them to act thus; but whatever the cause, there is the simple fact. Indeed there are many curious things which come under the notice of the gardener for which he cannot account: for instance, I have a grand border of *Chianodoxa Lucilæ*, about 40 feet long, containing thousands of bulbs, but neither there nor in other parts of my garden wherever it appears (for it is almost a weed), have I ever seen a slug; but a friend who is a well-known and successful grower of herbaceous plants and bulbs, says he cannot keep it on account of their depredations. An allied plant, *Puschkinia scilloides*, I have never been able to keep for the same reason. *Wild Rose.*

—In the issue of the *Gardeners' Chronicle* for March 19, Dr. Bonavia asks if any one can suggest a remedy against the mischief sparrows do to Crocuses. For some years I have protected mine by running a black thread, supported by sticks 8 inches high, along the lines, and the birds never touch even the yellow ones. A few yards away, where the same precaution is not used, scarcely a Crocus is spared. As to the vagaries of sparrows, I can offer no explanation, though this year I have noticed that our public gardens have, in many spots, suffered little in comparison with former years, and the gardeners suggest that the birds are not so numerous. Here and there they seem to have acquired a taste for Scillas, and these have had to be guarded by threads, like the Crocuses, and with the same perfect success.

In fact, the sparrow will not go near any tree or plant near which it detects the black thread. *W. F. Melvin, Dilkusha, Montrose.*

THE SAN JOSE SCALE.—I see it stated in your pages, from an eminent authority on such subjects, that we have nothing to fear from the San José Pear scale in this country, because it is not likely to thrive here. Perhaps not, but I would like to know the difference between the San José scale and the Apple-scale of the same name in this country—"Aspidiotus," or the Pear-tree oyster-scale—"Diaspis," both already common in British gardens, and so much resembling in description the San José scale that should not be the least surprised if they turned out to be the same, and that California got the scale from us instead of the reverse. The affected Pear, figured in your columns on Feb. 12, has an old acquaintance and peculiar look about it to one who has good reason to remember its depredations—only the Pear-scale is smaller and more oblong in shape. The latter, when it attacks the Pear, usually covers the bark so thickly to the extremities of the shoots, that you can hardly lay your finger on an unaffected spot. Many years ago, when the writer was under Mr. McIntosh at Drumlanrig Castle gardens, Dumfriesshire, a wall of Pears was threatened with destruction by the scale, to destroy which, as a desperate remedy, Mr. McIntosh had the trees painted with spirits-of-tar—a very long and disagreeable job in cold weather. The "cure" was perfect, but the tar destroyed all the fruit and leaf-buds as well, and the trees did not come into leaf till June and July, and the foliage was produced from adventitious buds that pushed from the smooth bark. I have never seen such leaves for size and luxuriance since. When I came to Wortley I found some wall-Pears similarly affected, and painted them with linseed-oil, which was nearly as effectual as the tar, but the effects of the scale are still visible on the old branches. The scale extended to the fruit, presenting exactly the same appearance as the figure given on February 12, only the scale was not so oyster-like in shape. I never saw the scale bad except on wall-trees, and I have been wondering if the San José variety is only a thriving offshoot from the British stock, favoured by a better climate, and hence probably its new name *Aspidiotus perniciosus* instead of *Aspidiotus conchiformis*. It is queer that in English the San José is named the same as our own variety in some reports, viz. the "Oyster Scale." *J. Simpson, Wortley.* [The San José scale is quite different. *Ed.*]

PASSIFLORA EDULIS AND OTHER SPECIES.—Like many of your readers, I was much pleased with your life illustration of the garden or true edible Passion-fruit in the *Gardeners' Chronicle* for Feb. 12. The middle fruit in the figure is a *fac simile* of the species that I have grown in greenhouse, orangery, and conservatory for years past. In such positions I have afforded the roots a border to grow in, and a soil consisting of two parts loam and one part peat. The growth of shoots was not stopped or much confined, unless an occasional stopping to furnish laterals where the area to be furnished was large. In mid-winter the lateral shoots were spurred in, like a Grape-vine, and the plants used to break freely and provide plenty of shoots furnished with foliage and flowers. In most cases no more warmth was used than would exclude frost, and not always that. Under this kind of treatment the plants were not infested with mealy-bug or other insect. The fruit to the right affords a good idea of the seeds and pulp with the rind removed; only grown in a cool temperature until quite ripe, the rind seems thinner in Nature than in the section. Nor must the shrivelled fruit on the left be taken as an indication that the ripe fruit on the plant suddenly shrivels when ripe. Like most other fruits, that of *Passiflora edulis* may, and does, shrivel, especially if grown in a very dry atmosphere, and in a stove temperature; but it is a long while about it, and is by no means a very perishable fruit. Were it not that this fruit is on the same plant as the central one, which is obviously the true *P. edulis*, one would almost be tempted to suppose that the fruit on the right had some connection with the warted species or variety of the same *P. edulis verrucifera*. [The name refers to the warts on the leaves and bracts. *Ed.*] I am very much obliged to "C. B." for confirming the fact that *P. edulis*, well-ripened, will stand 5° to 10° of frost, which I have frequently verified. We are all agreed that this tropical Passion-fruit, whether under the erroneous name of *P. quadrangularis*, *macroparpa*, *alata*, of several species or varieties, or any

other, could not live, thrive, nor produce edible fruits under such cold conditions. The size of the fruit is also so very different; its character, as you have already pointed out, very unlike. The true edulis is not much bigger than a bantam's egg, nor more than $1\frac{1}{2}$ inch in diameter. The fruits of some of the tropical species of *Granadilla* may range from four to eight pounds in size and weight. And yet, unfortunately, the names of these edible Passion-flowers tells us little or nothing of their fruit. The best to eat, the easiest to grow of them, all our edulis, possibly got its name because the fruit of this species are produced in the greatest abundance for the longest period. But every Passion fruit that can be sucked, sipped, eaten with a table or teaspoon, or knife and fork, or otherwise, is equally entitled to the name. And then, nearly all our other names, such as the several varieties of *alata* and *quadrangularis*, &c., are mostly descriptive of leaves, stipules, stems, and flowers, rather than fruits. But *P. macrocarpa* is generally understood as applying to the fruit. But then, the stems and character of this fine Passion-flower are so like those of *P. quadrangularis* that they have got greatly mixed in practice. [The flowers are very different. Ed.] And this confusion has not been lessened by the appearance of *P. Hulletti* of gardens as *P. macrocarpa*. There are several other edible species and hybrids. But with the true edulis, occasionally grown as *P. incarnata*, which comes pretty true from seeds, and is readily rooted from cuttings, and one of the best of the tropical *Granadillas*, under the name of *alata*, *macrocarpa*, *quadrangularis*, or, mayhap, *amabilis*. The Editor would greatly oblige growers if he would kindly advise us under which name the finest of these tropical Passion-fruits—so distinct and different from the true edulis—is likely to be had. [*macrocarpa*. Ed.] Altogether independently of the edible merits or demerits of their fruits, few plants are more worthy of a place of honour or coign of vantage on the walls, rafters, or roofs of our plant-stoves for their towering stems, fine foliage occasionally variegated, as one variety of *quadrangularis*; curious tendrils and stipules, curiously formed; and richly-coloured flowers steeped in fragrance and sentiment. To these charms and graces may also be added the form, colour, and size of their growing fruits. I have not seldom felt and thought that these magnificent flowering, fruiting, fine-foliage plants, would probably be far more common in our plant-stoves if cultivators would cease trying to eat their riper fruits, and be content to feast their other senses on their marvellous fragrance and matchless beauty. Failing this consummation so devoutly to be wished, let us accept or reject these tropical Passion-fruits as an extra blessing, or otherwise, as taste or palate dictates; always excepting, however, from this self-denying ordinance *Passiflora edulis*, which, when grown in a cool temperature, is well worth eating in many ways. *D. T. Fish, Fettes Row, Edinburgh.*

HARDY PLANTS FOR FURNISHING FLOWERS FOR CUTTING.—In continuation of my remarks on p. 188 of the issue of the *Gardeners' Chronicle* for March 26, that when I mentioned in my previous communication, English and Spanish Irises and double-flowered Daffodils, I had in my mind bulbs planted in the autumn. All the same, there is no practical reason why people who may come to the conclusion in February, early in March, or, for that matter, as late in spring if good dry bulbs of the Daffodil and Iris are then obtainable, that they would like to plant a given space with these popular bulbous plants, should not forthwith do so. By doing so they gain time and strength, and obtain better floriferous results twelve months later than bulbs of the same size and quality planted the previous autumn will produce. Moreover, a few flowers will be secured from the spring bulbs the same season. Mr. Jenkins must know that thousands—hundreds of thousands—of Irises and Daffodils are advertised and sold during the months of January, February, and March, and he must also know that the said bulbs are purchased to be planted and, in many cases, the flowers are turned into money. Mr. Jenkins may like to hear that the *Francoa ramosa* is not an "unsafe" plant, with every one out-of-doors. I have had it grow and flower freely in light soil, and sheltered from the north and east winds. The *Francoa* is a Chilean plant, but it has long since been naturalised to many growers in southern and western counties in England and Ireland. I omitted to say, when speaking of the *Alstroemeria*, that I sent pot-plants in six varieties to a customer residing in the west of Scotland last autumn for planting out-of-doors, and I hope to report on these in due time. My select list of

perennial plants did not purport to include all good perennials, only a portion of them, and Mr. Jenkins will do a service in including those which I, in order to save space, omitted from my list. *H. W. Ward, Rayleigh.*

FREESIAS.—I would have answered "W. L.'s" enquiry in the *Gardeners' Chronicle* before, but I have been abroad for some days. I grow mine in Amoy, China, out in the open; the soil I grow them in is light, and inclined to be sandy, and the drainage very good. The climate of Amoy is very similar to the climate at the Cape, whence, I understand, *Freesias* originally came. There is a dry season from October to January (after this much rain till the end of September), with almost no rain. I plant my bulbs in September or October, and they flower in February. I take up the bulbs about the end of May, dry them off and keep them out of the ground till planting time. I can only account for their fine growth on the supposition that the climate just happens to suit them. I give no manure or stimulant of any kind—of course, the bulbs are watered while making growth. My bulbs originally came from Foochow, where they do equally well; and they were imported into Foochow some years ago from the Continent (Europe). I fear my experience abroad will not help you much at home, but such as it is you are welcome to it. *Ixias*, *Callas*, *Sparaxis*, &c., do also very well with me. *W. H. Wallace, Colchester.*

GARDENERS' ROYAL BENEVOLENT ELECTION.—I venture to suggest a remedy to the committee and governing-body of the Gardeners' Royal Benevolent, viz., to make a rule that all voters give two-thirds of their votes to candidates who have been subscribers, the other third, if they choose, to non-subscribers; this would allow only a small percentage of non-subscribers getting the pension. Certainly something should be done to give encouragement to those who intend becoming members, and satisfaction to present ones. I am always advising young gardeners to join while they are able to pay their subscriptions. I am afraid they will hang fire if they find so many get the pension without paying a penny. *A. J. Long.*

—I am writing to give my support to what Mr. Denning has to say in *Gardeners' Chronicle*, at p. 172. It seems strange to my country mind to see such nonsense written about the institution by men who by this time should have had the small amount of perception necessary to get at the truth in this matter. What I mean by this term is in reference to the patience and liberality of yourself and some of your contemporaries for some years past in granting space for the free discussion and expounding the principles on which the institution is based. Though I have known Mr. Denning for thirty years, I have not seen him for over half that time; all the same I am pleased to see he has still the power of putting the truth of any subject he deals with in a small space. I would like to add this thought to what he says. Through the publicity given to the matter by the horticultural press and otherwise, all, or nearly all, the cases of distress are brought forward. Unfortunately we do not get hold of all those who from either self-interest, duty, or human sympathy, might, and ought to, subscribe to its funds. To my mind, this is the ferry that wants bridging over. *H. J. C. Grimston, Tadcaster.*

APPLE BLENHEIM ORANGE.—There is growing in the village of Welford-on-Avon, Gloucestershire, a monarch-tree of this very useful variety, which I should estimate is 150 years old [?]. It is in most robust health, and was a most glorious sight in September, 1895. That season there were gathered from the tree over forty bushels of well-coloured fruits of high quality. *F. P., Leamington.*

INARCHING AND GRAFTING VINES.—If I want to place a variety on a permanent Vine, I prefer inarching to grafting, as when performed on the current season's growth the union soon takes place. The young wood being very soft and very brittle, much care must be exercised in carrying out the work. Having settled on the point of union, the pot containing the new Vine must be made firm and safe in a convenient position for bringing into contact with the old Vine. The young wood in each case should have acquired some solidity before the splicing is attempted. This is simply done by paring off a thin strip from each, joining the surfaces accurately together, and keeping them in position with soft damped raffia pulled softly. An examination should be made in ten days, and if it be seen that the bandage is too light, it must be replaced with another. In order to attach grafts to a young Vine,

the latter should have made some amount of growth, so as not to bleed when cut, and the scions to be employed should be subjected to a slight degree of warmth before they are made use of. The length of new wood on the stock should be fully 6 inches, and the scions should be two joints, or three eyes. Almost any form of grafting may be employed, and as a covering to keep out wet, wax or clay may be employed, binding fresh moss round the part, and keep it moist. *H. Markham.*

ARAUCARIA IMBRICATA.—In reference to the note on p. 188 respecting *Araucaria imbricata* ripening seed, I may say that we have a number of fine specimens in the grounds here, of which several frequently ripen seed perfectly. Last year one specimen bore upwards of thirty large cones. If the seeds are not secured directly, they drop from the cones, the rats and rabbits devouring them. *A. Goswell, Pitshill Gardens, Petworth.*

ALSTRÖMERIAS.—I consider *A. aurantiaca*, *A. chilensis*, and *A. psittacina* to be perfectly hardy in this district if planted 6 inches deep. To these may be added *A. aurea*, which most botanists consider identical with *A. aurantiaca*, though it is sufficiently distinct for market and garden purposes. All of these survived the severe winter of 1895-96 without injury and without protection. This was a sufficient test in our cold clay soil, and the temperature as low as 8° below zero on the ground. I grow a large quantity, and it would not be difficult to cover an acre of ground with them in a short space of time, for they increase rapidly, and are not particular as to soil, provided they are planted deeply. I find them extremely useful for providing flowers for cutting, as they last so long in water. But their value for market purposes may be very low at present, because it requires a long time to induce the dealers to try a fresh species, and these do not bloom outside until almost the close of the London season. The above varieties give a good succession of bloom, commencing about the middle of July with *A. chilensis*, a fortnight later *A. aurea*, and *A. aurantiaca* blooms, and *A. psittacina* two or three weeks later. All of them should be planted at the end of October, and then remain undisturbed for several years. Seeds should be sown in pots as soon as ripe. I do not find the plants are weakened by cutting, although this takes away the greater part of the foliage. *A. versicolor* survived the winter in Kent for several years when I was a boy at home, but I have not tried it here; and *A. pelegrina alba* is too scarce at present, although in pots it appears to grow freely. Four other species are mentioned in *Nicholson's Dictionary of Gardening*, but they appear to be very scarce, as I do not find them in any catalogue, or in the *Kew Hand-List*. The latter list mentions three more that are not in the Dictionary. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

NURSERY NOTES.

MESSRS. J. LAING & SONS.

A HURRIED call some few days since at the Forest Hill Nurseries revealed a fine display of *Cliveias* in bloom, which served to show the much greater variety now presented by an up-to-date collection of these useful greenhouse plants than formerly. There is no white-flowered *Cliveia*, nor a blue one, and the differences the flowers exhibit in colouring are, of course, modifications in shade or tint. Still, these are sufficiently distinctive to give to the collection an interest that would be entirely wanting in a group of plants of the species *C. miniata* and *C. nobilis*. In the form of the flowers also there has been obtained an advance quite as marked, and the old "starry" narrow-petalled varieties that resembled the worst forms of *C. nobilis* have been succeeded by others with wider segments, that imbricate very prettily, and constitute a campanulate form, rather more like the flower of a *Vallota*. In one of the most recent seedlings, for instance, this is very apparent. It has been called *Dazzler*, which indicates that the flowers have a brilliant colour as compared with most *Cliveias*. The throat is white and yellow internally, owing to the basal portion of each segment being striped in the centre with yellow, whilst the margins remain white. But the flowers are most remarkable, as we have said, in that they are round, that the segments imbricate, and that

they recurve very beautifully. Queen Victoria is a seedling, possessing a yellow throat and stamens, whilst the tips of the segments are of a very soft shade of colour, that may be compared to flesh. The umbels carried fifteen or sixteen flowers upon each. The Rev. J. H. Foster, also new, was just passing. The flowers have a whitish throat, and are very faintly coloured throughout. There were ten flowers upon a noticeably short spike. Duke of Teck and Comet may also be mentioned as very meritorious among recent new ones. Vesuvius, among catalogued varieties, is one that can be well recommended, owing to the flowers being of good form and brilliantly coloured. Harry Laing, Earl of Rosebery, and last, but not the least valuable, John Laing. For half-a-dozen years the last-named variety has appeared to us the best in the collection, and probably it is unsurpassed even now, though the new Dazzler, in point of form at least, is an advance. Cliveias are not exacting plants in any way, and when out of flower even are ornamental, but they produce so fine a display in early spring that few gardeners should lack a collection.

Messrs. Laing's Caladiums look beautiful just now, and one of the largest of the houses is almost filled with the extremely delicate-looking young leaves of innumerable tints. But we hope to see them again before the Temple Show, where the groups of these popular plants are likely to be more numerous than ever.

"Pricking out" is the order of the day in the Begonia department, and as every tiny seedling is "pricked" twice, the work entailed by so many thousands is considerable. Still, such work is not lost, for seedlings of most plants may be grown more rapidly by frequent "pricking," and this is probably because the surface of the fresh soil allows the greater amount of fresh air to enter.

MESSRS. J. VEITCH & SONS, LIMITED.

The feature of the Chelsea establishment of Messrs. James Veitch & Sons at the present season is the houseful of Hippeastrums, the plants being at their best. No change has been made in the arrangement of the plants, and the flowering ones still occupy the central bed of the long span-roofed glasshouse, and the young and mostly flowerless representatives of potentially fine varieties, the narrow beds at the sides of the house. The home-strain of Hippeastrums is admitted to have reached the utmost limit of size, and it is now the endeavour of Mr. Heale, who is entrusted with the management of the bulbs, to obtain marked and pleasing variations of colour, or of markings, be these shown in feathering, bands, stripes, spotting, or edging. And the flowers are constantly disclosing traces of some or other of them. Mr. Heale's chief ambition, and one the realisation of which would afford the firm the greatest gratification, would be the appearance of a yellow or a white self. Numerous instances have occurred of white as a ground for shades of red, crimson, &c., but no wholly white blossom; and yellow appears, or seems to appear, as greenish-yellow, of undecided nature in a few recently-raised flowers, but this is quite enough to give the cross-breeder hope of future realisation. The other direction in which improvement is sought is in the extension of the width of the segments, especially of the lower one, as this tends to make a more symmetrical flower, although some of us think that in obtaining this point, piquancy and pleasing irregularity are injuriously deleted. All kinds of flowers do not fit into a circle, or are improved when they are made so to do.

The best of those open on the day of our visit were Tamaris, of brilliant scarlet, which seen against the light shows darker reticulation. The segments are of desirable breadth. Adana is a crimson variety of fine form and large. Balanus is of purplish-crimson, with an undefined white band in the middle of each segment; a tall and strong scape. Edom, bright scarlet, with a central white band, and a faint vestige of green in the throat. Ridones is an orange-scarlet; a large and symmetrical flower. Cyrene is a deep crimson self, in form extra good, having broad segments; Macedo is another self, of about the same tint.

Sylph is a white-ground flower, with rose-coloured veins, the white running into green at the base, as is a common feature with many. Emo is of bright scarlet, with a distinct eye, and an excellent form. Macerio is a finely-reflexed flower, white, with bold scarlet veining, especially marked on the upper three segments. Hermatus differs a little from the last, in possessing fainter marking and less reflexed segments. Cresswick is a deep crimson, of regular outline. Favorinus has a crimson feather on a greenish-white ground, and is a distinct fine form. Jobates is a pretty reflexed flower, white, with "green in his eye." Racilia is a flower having narrow segments, almost a crimson-coloured self, showy and distinct. Farfaros has a crimson feather on each upper segment; the lower ones are lacking in breadth. Varnia is a purplish-crimson flower, with much green at the base; and Paches is a very dark crimson self. Of the flowers out when we saw them, the best were most decidedly dark-coloured, although on surveying the bed we should have said that lights and darks were about equal in numbers, the central bed holding about 1100 plants.

Warm-house Rhododendrons were making a small show, and we remarked several varieties of *R. balsaminiflorum*, of *R. multicolor* var. Neptune, Ceres, Ne Plus Ultra, *jasminiflorum*, and the old Princess Alexandra. The stock of plants showed, in the healthy colour of their foliage, vigour of growth, and well-regulated trimness, how well their culture is understood.

The Cliveias made a splendid bit of colour in a small house, but having noticed the best of these plants in our report last week of the Royal Horticultural Society's meeting, nothing further need be said beyond the fact that we saw no pure orange, yellow, or white-flowered one; but these are sure to come.

In the Orchid-houses, plants were noted of *Dendrobium Hildebrandi*, flowers yellow and white, a good winter bloomer; *D. Wiganæ*, primrose-yellow, with a crimson base to the lip, a cross between *D. nobile* and *signatum*; *D. Euterpe*, a cross of *D. Wardianum* and *nobile*; *D. Cybele*, and *D. Rolfei*; a quantity of *Oncidium ampliatum* coming on, with flower-stems of great strength; and a variety of *Cymbidiums*, *Epidendrums*, &c., in bloom in the rock-house.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

MARCH 22.—*Present*: Dr. M. T. Masters (in the chair), Prof. A. H. Church, Mr. J. Hudson, Mr. Michael, Mr. A. Sutton, Prof. Church, Dr. Müller, Rev. W. Wilks, and Rev. Prof. G. Henslow, Hon. Sec.

Orchid Roots with Fungus.—With reference to the nature of the fungus attacking Orchid-roots in a damp atmosphere, referred to at the last meeting, Dr. W. G. Smith, of the Yorkshire College, Leeds, writes as follows:—"The Orchid aerial roots sent contained a fungus which lives on them, and has killed some already. The absence of any form of reproductive organs renders it impossible to identify the parasite. Other portions of diseased plants (i.e., leaves) would be required to ascertain the true nature of the fungus. The fungus present attacks living cells, consumes the food laid up by the plant, and finally kills the roots. A disease having somewhat the same effects has been found in the Vanilla plants of Mauritius."

Palm Leaves Discoloured.—Mr. W. A. Holmes, of the Putney Nurseries, sent some portions of Palm-leaves with numerous translucent spots. They were received from the Continent. An examination appeared to indicate a previous attack by insects, but none were present, the interior tissue having disappeared from the spots; so that the new leaves would probably be quite healthy.

Vine-Browning.—Mr. Hudson showed a young shoot, the leaves of which were blistered and brown. This is due to the presence of myxomycetous fungus, *Plasmodiophora vitis*, allied to *P. Brassicæ*, the "slime fungus," which gives rise to "club disease," or "finger and toe," in cultivated cruciferous plants. The only remedy is to cut away and burn all affected leaves or shoots. It is described and figured in Viala's *Maladies de la Vigne*, p. 400.

Ivy Sports.—Dr. Masters exhibited sprays of a peculiar small-leaved dwarf Ivy, remarkable for sending up vertical shoots with distichous leaves, though unattached to a wall. The habit appears to have become fixed, even in free-growing branches. On some shoots, however, the leaves were spirally arranged, as is usual on such branches. It may be observed

that the change from the distichous arrangement of the leaves on the horizontal branches of the common Laurel to a spiral one, when the boughs grow erect, is common; but it is not a fixed character.

CORNWALL DAFFODIL AND SPRING FLOWER SHOW.

MARCH 15, 16.—This meeting, due in its first beginning to the enthusiasm and foresight of the Hon. John Boscawen of Tregye, Perranwell, has quite outgrown its local character, and bids fair to become the most important of our early exhibitions.

It is indeed somewhat strange that the great value of such a fixture did not years ago occur to the Cornish professional and amateur growers, considering the unique adaptation of Scilly and much of the mainland of Cornwall for the production of flowers in the months which are still winter up-country, and the ever-increasing demand for early produce by the large towns. The Narcissus industry of Scilly is now an old story, but until the last two years, there has been no exhibition at a Cornish centre where all those interested in such floriculture could meet and confer upon the best flowers and the best cultivation.

The Show this year was held in the Concert Hall, Truro. Could the severe check—even in Cornwall—brought about by the weather of March have been foreseen, no doubt the flowers would have benefited in both quantity and quality by a postponement to a date one week later. Still the entries were far in excess of those of 1897, and the quality, though scarcely equal to that of last year, which was a wonderful season, was excellent. Of the cut *odendron* blooms it may be said that they were wonderful; probably many visitors who gazed upon Mr. D. H. SHILSON's magnificent display of crimson, pink, and white had never dreamed that such flowers could be produced in England out of doors in the first days of March. The finest stand of Narcissi, taking into consideration both variety and quality, came, as might be expected, from Mr. DORRIEN SMITH of Treco, Isles of Scilly. Every variety of note, except a few of the very latest, was represented, and the flowers were perfect in substance, size, and colour. The Silver Cup offered by Messrs. Barr & Sons, of Covent Garden, was won by the Rev. A. T. BOSCAWEN with a beautiful collection, showing skilful cultivation and the excellence of the soil at Mount's Bay. Mr. P. D. WILLIAMS of Lanarth, St. Keverne, took the cup given by Mr. T. S. Ware, with a stand in no way inferior. The prize for the best new seedling Narcissus fell to the share of Mr. J. C. WILLIAMS of Caerhays Castle, St. Austell, the President of the Society. In the classes for double and Polyanthus Narcissi—both of these most valuable market kinds the production of which should be encouraged by our shows—Lady MARGARET BOSCAWEN was easily 1st. Splendid scarlet *Anemone fulgens* was staged by Miss M. H. WILLIAMS. In the Rhododendrons classes, the board was swept as usual by Mr. D. H. SHILSON. Extremely fine Violets, Parma and Marie Louise, were shown by Lady M. BOSCAWEN. In all the classes there was close competition, and the available space was fully taken up. Messrs. BARR, WARE, VEITCH of Exeter, and DICKSON of Chester, staged large collections of spring flowering plants and shrubs. The committee are much to be congratulated on the deserved success of this meeting.

SHIRLEY GARDENERS' MUTUAL IMPROVEMENT.

MARCH 21.—The annual general meeting was held on the above date, the President, Mr. W. F. G. SPRANGER in the chair.

The report showed that twelve meetings had been held during the past year, and that the attendances amounted to 516, averaging 43 members per meeting. There was a balance of £3 odd in favour of the Association. The President, Vice-President, Treasurer, and Secretary were re-elected, and a committee of fifteen members chosen by ballot. After the business of the evening, there followed an entertainment, which was much enjoyed.

TORQUAY SPRING SHOW.

MARCH 23.—The Torquay District Gardeners' Association, under whose auspices the flower-shows are now held, achieved a distinct success on the above date. The centre of the hall was filled with circular groups of miscellaneous plants, there being keen competition.

Mr. W. Satterly, gr. to Miss RAWSON, was 1st with a well-grown and tastefully set up exhibit. The Orchids shown by Mr. G. Lee, gr. to Miss LAVERS, were a great attraction, as was the stand (not for competition) shown by Mr. W. Bale, gr. to J. Snelgrove, Esq.

The greatest novelty was an artificial lake with electrically illuminated fountains which was laid out by Mr. F. W. Meyer of Messrs. R. VEITCH & SONS, Exeter, at the suggestion of the Association. The Cinerarias made a showy display, the chief honours for which were secured by Mr. F. C. Ferris, gr. to J. W. Kimber, Esq.

MESSRS. W. ALLWARD, W. BURRIDGE & SONS, CURTIS, LANGFORD & CO., LTD., W. B. SMALE, MESSRS. BEACHEY & CO., and the South Devon Fruit Farm, also exhibited.

The Cyclamens shown by Mr. R. W. Holder, gr. to Mrs. S. BARKLEY, were also noteworthy.

SOUTHAMPTON HORTICULTURAL.

MARCH 29, 30.—The first spring show was held by the Royal Southampton Horticultural Society in the Victoria Hall, and from a horticultural point of view it was a great success.

The usual spring-flowering exhibits were contributed in fresh and good condition generally. Mr. Carr, gr. to W. A. GILLET, Esq., Fair Oak Park, Bishopstoke, won 1st prize with a collection of Orchids, interspersed with Ferns and foliage plants, staging many well-flowered examples. Mr. Carr also contributed the most pleasing group of miscellaneous plants arranged for effect. Mr. Peel, gr. to Miss PEEL, Sidford Lodge, Shirley, was 2nd in this class. The last-named exhibitor secured premier award for eight specimen stove and greenhouse plants, with fairly good examples.

Mr. Mitchell, gr. to J. WILLIS FLEMING, Esq., Chilworth Manor, had the best-flowered Azaleas. Mr. WILLS, florist, Shirley, staged the best Hyacinths in twelve varieties. Mr. CARR contributed creditable Primulas and Cyclamen, and Mr. MITCHELL some Lily of the Valley. Mr. Horsey, gr. to J. P. E. D'ESTERRE, Esq., Elmfield, Millbrook, 1st, had a really good exhibit of Cinerarias. Cut flowers in epergnes and baskets were attractive. Miss WADMORE, Basingstoke, occupied a similar position in the last-named section.

Miscellaneous contributions for exhibition only were numerous and pleasing; and those of Mr. LADHAMS, Mr. WILLS, Messrs. LONGSTER BROS., and Messrs. BRIGHTMAN and ANDREWS were conspicuous for good quality. Mr. FUDGE, as usual, carried out very efficiently the Secretarial duties.

BRIGHTON AND SUSSEX HORTICULTURAL.

MARCH 29, 30.—This, the first show of the season, was excellent in almost all classes, both for the number and quality of the exhibits.

Open.—Mr. J. Hill, gr. to C. WALLIS, Esq., Springfield Withdeane, won in the chief class for groups, having a very pretty arrangement of easily-grown plants; followed by Mr. G. MILES, Dyke Road Nursery, who was also placed 1st for a table of plants.

Mr. J. Harper, gr. to E. A. TUCKER, Esq., Vernon Place, Preston, was 1st for a collection of Orchids, *Lycaste Skinneri splendens*, *Sophronitis coccinea*, *Cattleya Trianaei*, and *Laelia harpophylla* being good; Mr. H. Garnett, gr. to R. G. FLETCHER, Esq., Mount Harry, Preston, 2nd, with a good lot of plants.

A mantelpiece and hearth decorated with plants was a new and attractive feature, and one which might be followed by other societies. Mr. G. MILES, Dyke Road Nursery, was 1st, and was followed by Mr. E. Meachen, gr. to Mrs. ARMSTRONG, Woodslee, Preston.

Hyacinths and Tulips were excellent. Mr. J. House, gr. to Sir F. MOWATT, K.C.B., Withdeane, being 1st, and Mr. E. ANDERSON, Preston Park Avenue, 2nd.

We have not seen Lily of the Valley and *Lachenalia* better or more numerous here; Mr. A. E. Golding, gr. to H. St. GEORGE VOULES, Esq., Dyke Road, was 1st for Lily of the Valley, and Mr. J. Turner, gr. to Sir GRENVILLE SMYTHE, Wick Hall, was 1st for *Lachenalia*.

The twelve pots of *Mignonette* from Mr. W. E. ANDERSON, and the *Spiræas* from Mr. G. HOUSE, also deserve special mention.

Cyclamen from Mr. C. Murrell, gr. to Mrs. JENKINS, Burgess Hill, and *Genista fragrans* from Messrs. W. MILES & Co., Hove, were much beyond the average; and the gardener, whose names are mentioned were the winners in the order of their names. Six grand *Hippeastrums* came from Mr. G. HOUSE.

Cut Flowers.—*Narcissus* were clean and good, and some fine boxes of twelve varieties came from Mr. J. Harper, gr. to E. A. TUCKER, Esq., Preston; and Mr. M. Tourle, gr. to F. BARCHARD, Esq., Horsted.

Stove and greenhouse cut flowers were well shown by Mr. H. Garnett, gr. to R. G. FLETCHER, Esq.

Cut Roses were not numerous. An excellent box of twelve blooms came from Mr. G. W. PIPER, The Nursery, Uckfield.

A stand for the table, to consist of natural flowers only, saw close competition. Mr. E. MEACHEN just winning the 1st prize; Mrs. TOURLE, The Gardens, Little Horsted, being 2nd.

Groups from the amateurs were good, and in arrangement and material they were well up to the average. Mr. J. R. CATTLE, Dyke Road, was 1st.

There was a large number of non-competitive exhibits, the best being miscellaneous plants from Messrs. BALCHIN & SONS; Messrs. CUTBUSH & SONS had hardwooded plants; Mr. G. W. PIPER, cut Roses; Mr. W. GOODCLIFFE, Ferns; and Messrs. CHEAL & SONS, fruit.

ROYAL BOTANIC.

MARCH 30.—This society held its first show for the present year on Wednesday last, and the exhibits were staged as usual in the Conservatory and adjoining corridor. The schedule contained thirteen competitive classes, but the exhibits in this section were extremely few, very little competition occurring in any class. The greater part of the display was due to the collections from the trade, which in many instances were most commendable.

Messrs. BARR & SONS, King St., Covent Garden, made an extensive exhibit of *Narcissus* blooms, *Narcissi* in pots, and

of Tulips in pots. The large trumpet sorts such as Sir Watkin, Obvallaris, Horsfieldi, Golden Spur, Princeps, Maximus, and others, were most represented, but the incomparable section was shown in some variety also. The choicest blooms, and the best varieties however were to be seen in pots. These included the new bicoloured Victoria, also Madame Plomp, Weardale Perfection, Glory of Leiden, and others.

Cyclamens were again shown in splendid manner by the St. GEORGE'S NURSERY Co., Hanwell, who had a large sized group of plants in flower.

The CHURCH ROAD NURSERY Co., also of Hanwell, were the exhibitors of a group of Cyclamens of much merit.

Messrs. WM. PAUL & SON, Waltham Cross Nurseries, Herts, exhibited a very large group of Hyacinths in pots, but the season being late the flowers were rather less effective than in the excellent display made by the same firm recently at the Drill Hall. Cineraria, flowers blue and purple, Emperor of the Reds, and Ball of Gold were among the novelties included. Messrs. PAULS' group of Roses in pots was very appreciable.

Camellias, as finely grown, abundantly-flowered plants and as cut blooms in boxes were magnificent, from Messrs. PAUL, of Waltham Cross, and were one of the very brightest features of the Show. Of novelties, Pride of Waltham is a first-class variety, producing large handsome flowers of deep flesh colour or pink, very prettily veined.

Messrs. J. CARTER & Co., High Holborn, London, showed a group of Cinerarias, representing a strain of large and brilliantly-flowered varieties, but less compact in habit than some.

Cinerarias were also shown by Messrs. A. W. YOUNG & Co., Stevenage Nurseries, Herts.

Mr. W. RUMSEY, of Joyning's Nursery, Waltham Cross, staged Rose blooms in eight boxes, which included a large number of flowers in considerable variety.

Mr. H. B. MAY, Dyson's Lane Nursery, Edmonton, had a small group of choice Ferns. Noticeable was a very pretty plant of *Lomaria ciliata* major; also *Nephrolepis plumosus*, a much-crested variety; *Asplenium ornatum*, the distinct and pretty *Gymnogramma Mayii*, *Pteris blaurita*, and *P. argentea*.

A very large group of Ferns was shown by Messrs. J. HILL & SON, Edmonton, a firm that has exhibited extensively of late at the Drill Hall and elsewhere. The group under notice was composed of capitally cultivated plants, and several of the genera, including *Adiantum*, were represented by choice varieties.

Messrs. T. JANNOCH, Dersingham, Norfolk, exhibited forced Lily-of-the-Valley in the form of small moss-covered pyramidal cones.

Orchids in a group were contributed by Messrs. HUGH LOW & Co., Bush Hill Park Nurseries, Enfield. Conspicuous in this exhibit were *Odontoglossum purpureum*, *gloriosum*, *Andersonianum* (very fine), *triumphans*, and *O. t. intensum*, a deeply coloured form; *Dendrobium Boxalli*, and *Cattleya Trianaei* were good.

Mr. T. S. WARE, Hale Farm Nurseries, Tottenham, contributed a group of *Narcissus* in pots, and a number of cut flowers in variety.

Messrs. B. S. WILLIAMS' very bright group from Holloway was composed of *Hippeastrums*, *Cliveias*, forced Lilacs, a few species of Orchids in flower, and a group of plants of *Azalea mollis*. A fine large white-flowered greenhouse *Rhododendron* named Madame Cuvalier was good. Of Orchids, there were plants of *Odontoglossum crispum*, *Coleogyne cristata*, *Zygopetalum Perrenondii*, and the pretty hybrid *Phaius Normanii*. A well-flowered plant of *Epidendrum radicans* was very effective. Of *Hippeastrums*, the varieties Gerald Balfour and Holloway Belle were most noteworthy. Some florists' arrangements of flowers by Messrs. Williams & Son exhibited much taste, a basket of Daffodil blooms being particularly commendable.

Messrs. LAING's group was a very miscellaneous one, and included many choice stove and greenhouse flowering and foliage plants. Some of the best *Cliveias* (see p. 205), from Forest Hill were shown, a few *Caladiums*, and several plants of the handsome variegated *Leea amabilis*, &c. A stand furnished with florists' arrangements and like exhibits was also contributed by Messrs. Laing & Sons.

A group of miscellaneous plants from Messrs. J. PEED & SONS, Roupell Park Nurseries, contained many species, with ornamental foliage, and in addition, plants of *Azalea mollis*, *Cliveias*, *Ericas*, *Liliums*, &c.

Mr. G. Kelf, gr. to Mrs. ABBOT, South Villa, Regent's Park, staged a group, in which a collection of spring flowers was conspicuous. The majority of these were Tulips, Hyacinths, Azaleas, *Narcissi*, Lily of the Valley, *Deutzias*, *Dicentra spectabilis*, &c.

Messrs. W. CUTBUSH & SON, Highgate, London, placed several well-flowered plants of *Magnolia Soulangeana* in the centre of their group, and this included *Acacias Drummondii* and *armata*, *Diosma capitata*, several species of *Erica*, *Boronia megastigma*, *Souvenir de la Malmaison*, *Carnations*, &c.

COMPETITIVE CLASSES.

The best collection of hardy spring flowers, cut or otherwise, was adjudged to be a group of hardy plants in pots shown by Mr. T. S. WARE, Hale Farm Nurseries, Tottenham. The most noticeable of these were *Fritillaria meleagris*, *F. m. alba*, *Muscari botryoides alba*, *Primula obconica*, *Orchis pallens*, *Scilla bifolia rosea*, *Hepatica triloba caerulea*, &c.

Mr. G. Cragg, gr. to W. C. WALKER, Esq., Percy Lodge, Winchmore Hill, was awarded 1st prize for six Orchids distinct, which included *Cypripedium Rothschildianum*, *Cattleya Schilleriana*, *Oncidium sarcodes*, &c.

A 1st prize was awarded to the St. GEORGE'S NURSERY Co., Hanwell, for a collection of twelve plants of *Cyclamens* in flower. These were in 7 or 8 inch pots, and admirable specimens.

The 1st prize for a group of six hardy Azaleas, was awarded to Messrs. MORLE & Co., Finchley Road, London; and a 2nd prize was taken by Mr. W. KEMP, Gunyale Nursery, Barnes.

Messrs. MORLE also showed some *Mignonette* in pots. For twelve Cinerarias, a 1st prize was taken by Mr. J. Mowbray, gr. to the Hon. H. C. LEGGE, Slough, who showed very large plants in 10 inch pots.

There was no exhibit in the class for twenty-four Hyacinths, and but one poor exhibit in that for twelve Hyacinths.

For the Silver Daffodil Cup offered by Messrs. BARR & SONS, King Street, Covent Garden, for the finest display of cut Daffodils of the three groups, *magni-coronati*, *medio-coronati*, and *parvi-coronati*, in not fewer than forty different varieties, the only competitor was Mr. W. J. GRANT, of Bassaleg, Newport, Mon.; notwithstanding the recent gale, which was very severe in that district, Mr. GRANT staged about sixty-five varieties, and, upon the whole, the exhibit was very commendable. The 1st prize was awarded Mr. GRANT.

On Saturday last, owing to the inclement weather prevailing, the supply of green vegetables was short, and high prices ruled. Due no doubt to Saturday's prices there were large supplies on Tuesday, but little demand and quantities remained unsold. Egyptian Onions are now on the market, and they appear to be very good.

POTATOES.

Diminished supplies of home-grown have been made up by larger arrivals from Germany, hence market has been steady. Present rates:—Maincrops, Saxons, and Bruce, 105s. to 120s.; Blacklands, 100s. to 110s.; Dunbar Maincrops, 130s. per ton. Foreign Ware, 4s. to 5s. per bag. New Potatoes, 11s. to 20s. per cwt. John Bath, 32 and 34, Wellington Street, Covent Garden, W. C.

CATALOGUES RECEIVED.

M. ROZAN-BOUCHARLAT, 88, Grand de Quire, Cuire-les-Lyon (Rhône)—Pelargoniums, Cannas, Fuchsias, Dahlias, Bouvardias, Abutilons, Hibiscus, Lantanas, Begonias, Chrysanthemums, &c.

THE NURSERYMEN, MARKET GARDENERS', AND GENERAL HAILSTORM INSURANCE CORPORATION, LTD.—The third annual general meeting of the shareholders was held on Thursday afternoon last at Simpson's Ltd., Strand, after our pages were made up for press. We shall refer to the proceedings in our next issue.

ARUM ETHIOPICUM: J. F. You have done quite right so far; still keep them in the vinery till they have filled the pots with roots, when you should afford them a shift into 32's, and about the middle of June they may be stood in a coal-ash bed in a sunny position to finish their growth, and afterwards to rest, turning the plants on their sides when the leaves begin to turn brown. Some growers plant them in trenches like Celery, but that is a method better adapted for late than for early work. Whilst the plants in pots are in an active state, weak manure-water should be afforded twice a week, stopping the application when full growth is reached. Having rested them by withholding water, the plants in the autumn should be placed in a cold pit or house where they will not be excited, or the soil rendered unduly dry by sun-heat before the period determined upon for starting them—say two months before spathes are required. The starting consists in gradually affording more water (they must never be kept quite dry), and placing them in a pit having a warmth of 55° by day and 48° by night, affording a few degrees more warmth as growth progresses, but never exceeding 60° by night and 70° by day. The best kind of soil consists of pasture loam one year in stack used in a rough unsifted state $\frac{3}{4}$, oxen manure $\frac{1}{4}$, and coarse clean sand; the potting done firmly, leaving plenty of space above the ball for holding water. The drainage should be good, but not excessive, and consist, therefore, of a few concave pieces at the very bottom, with fine, clean crocks above these.

BOOKS: F. S. S. Hardy *Coniferous Trees*, by A. D. Webster, published by Hutchinson & Co., 34, Paternoster Row, London, E.C. Hardy *Ornamental Flowering Trees and Shrubs*, by the same author, published at the office of the *Gardening World*, 1, Clement's Inn, Strand, London, W.C.—H. S. P. You will find the *Manual of Stove and Greenhouse Plants*, by B. S. Williams, published at the Victoria and Paradise Nurseries, Upper Holloway, one of the best. The late Thomas Baines' *Greenhouse and Stove Plants* contains much useful information. It is published by John Murray, Albemarle Street, Piccadilly, W.

CINERARIAS: A. C. The appearance is due to the fusion of several flower-heads into one. Doubtless in time it might be fixed, and would then be very ornamental, but you would require patience.

CLIVEIA: E. R. We can find no insects or fungi on your plant. The brown patches are cork formations, and have arisen, we suspect, after irritation to the epidermis by insects (e.g., red-spider) when the leaves were in a very young condition.

CELOGYNE CRISTATA: G. D. Place it in a warm-house, and it is a very easy plant to grow. Keep it well supplied with rain-water until the bulbs are fully made up, then remove to cooler house, and restrict, but not withhold, the water until the flower-spikes appear. Half-pots or Orchid-pans are better than the ordinary pot.

CELOGYNE CRISTATA ALBA: F. Archer. Without doubt the atmospheric conditions are unsuitable for your plant of *Ceologyne cristata alba*. It is a moisture-loving subject at all times, and being suspended to the roof it is in dryish air. Place the plant down upon the stage in a warm, moist corner of the house, and during the season of active growth afford water copiously, and an occasional overhead syringing at the time of closing the house when the weather is suitable. H. W. W.

FUNGUS ON TOMATOS; O. M. Bitters. This minute fungus can with difficulty be guarded against in warm moist glasshouses. The best kind of preventative treatment consists in affording the maximum of light, as much ventilation as is consistent with progressive growth, and plenty of

space between the plants, and generally growing the plants "hard," soft succulent growth being very liable to attacks of fungus of different species. Seed taken from much-forced and debilitated plants should be avoided. Use as a precaution at intervals the Bordeaux Mixture, or sulphide of potassium, $\frac{1}{2}$ oz. in 1 gallon of water.

GRUBS ON ROOTS OF RANUNCULUS: H. H. Carlisle. Larvæ of one of the "Swift" moths (*Hepialus*). As they are now about full-grown and very conspicuous, it would probably be better to lift the plants, turn over the soil and pick out the grubs. A look-out should also be kept for the pupæ, as some of the grubs have probably changed by this time. Do not frighten away insectivorous birds, such as starlings, blackbirds, and thrushes. R. McL.

INJURY TO TULIPS AND SPIREAS: Jas. Long. We have not sufficient knowledge of the circumstances to decide what has caused the injury, but you are very likely to be right in suspecting the cesspool.

LILIUM HARRISI: Lilium. The leafy shoot has been formed prematurely, and will not produce flowers this season. It is not possible to say why it has taken on this growth.

LINDLEY LIBRARY: H. R. Received with thanks, the sum of 21s., for the Lindley Library. The amount has been paid into Coutts'. M. T. M.

MOUNDS MADE ROUND TREES: Sycamore. The effect of piling earth over the roots to the depth of 3 to 5 feet, will probably be to kill them, by depriving the roots of air. If you can build a rough sort of wall for a distance of 5 feet all round each stem, the evil will in a measure be prevented. As the trees are only twenty years old, it would be better to lift them this season, with large intact balls, and replant on the new level of the ground.

NAMES OF FRUITS: Philomathus. Pear Verulam, useful for culinary purposes only. We do not recognise the Apple.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—Philomathus. *Rhipsalis salicornoides*.—T. T. 1, *Metrosideros floribunda*; 2, *Rhipsalis cassytha*.—B. W. M. 1, *Blechnum occidentale*; 2, *Goldfussia isophylla*; 3, *Acacia grandis*; 4, *Cyrtomium falcatum*; 5, *Asparagus plumosus*; 6, *Asparagus decumbens*; 3, *Calacia (Senecio) ficoides*; 8, *Sisymbrium Sophia*.—B. A., *Ormskirk*. 1, *Lycaste fulvescens*; 2, *Epidendrum cochleatum*; 3, *Smilax aspera*; 4, next week.—Sheffield. *Dennstaedia davallioides*.—J. R. 1, *Echeveria retusa*; 2, *Celsia cretica*; 3, *Oxalis acetosella*; 4, *Pteris aquilina* (Bracken); 5, *Nephrodium molle*; 6, *Tradescantia variegata*.

SMILAX (MYRSIPHILLUM) ASPARAGOIDES: Smilax. The plant is doubtless in an unhealthy state, and you would do well to turn out the ball, and ascertain the state of the soil. It is not a very free-rooting subject, and the soil may have become sour from applications of water and manure-water, and from the small demand made upon it by the roots. It should be in growth at this season if in health. The plant is a trailer, and should be afforded a long piece of twine on which to ascend, otherwise it will remain a dumpy ill-shapen mass.

VINE LEAVES: F. W. The specimens sent are quite insufficient from which to determine the cause of the injury to your Vines. There is a disease known as "browning," the effect of a slime fungus, and figured in the *Gardeners' Chronicle*, August 19, 1893, p. 217; but whether it is this, or mere sun-scorching, is not clear.—G. B. We have found no fungoid disease in the leaves after most careful cultivation to develop such if present. The black spots appear to have been caused by the sulphur. If the Vines cause further trouble, you may send fresh specimens.

WOOD: A. Tester. It is a piece of Bog-oak, which has been preserved probably for unknown ages by the preservative properties of a peat-bog.

THE Gardeners' Chronicle.

SATURDAY, APRIL 9, 1898.

COBBETT'S "ENGLISH GARDENER."

EVERY age has had its political or social firebrand—a prophet crying in the wilderness, a reformer fulminating in the crowded thoroughfare. Regarded almost invariably by their contemporaries as dangerous iconoclasts, if not as incurable lunatics, posterity, where it does not directly reverse such verdicts, nearly always modifies them very greatly. In an astonishingly large number of instances, the abuses which the governing portion of one generation regarded with perfect equanimity, have come to be recognised by the next as intolerable, so that the prophet who is disregarded and even condemned in his own age, becomes, in the course of time, accepted as a patriot and a reformer of a high type. His theories are put into practice with the most beneficial results—leaving the community at large to wonder, not so much at the existence of anomalies, as that they should have been tolerated for so long a time. The closing years of the last century and the opening ones of the present were marked by many deeply-rooted abuses, of which we at the present day, with our comparative immunity, can form no adequate conception. The number of men who were protesting, verbally and through the medium of the press, was, all things considered, very few. William Cobbett was one of the most vehement and uncompromising of this small band. Most of the others have faded into a respectable obscurity, but Cobbett looms largely in the crowded canvas of his period.

With Cobbett's politics, his quarrels, and his various escapades, we have in this place nothing to do. There is, however, one phase of his career which has been very much overlooked, and that is the conspicuous ability with which he wrote on gardening and allied subjects. When it is remembered that this man was the son of a farmer and publican, that he was absolutely self-taught, and that he wrote well on an infinite variety of topics, it will, I think, be seen that he fully utilised the opportunities which were placed in his way. He was a striking contradiction of that time-honoured fallacy, that "a rolling stone gathers no moss," for perhaps no man wandered more than Cobbett; and certainly none "rolled" with such advantage as he. Cobbett was born at Farnham, Surrey, in March, 1762, and after spending some years at work in the fields, he came to London and obtained a situation as a copying-clerk to an attorney; his next move was to enlist in a line regiment, and for some years he was stationed in Nova Scotia, obtaining his discharge in 1791 "with honourable notice."

He emigrated to America, and developed into an "author by profession," writing pamphlets, translating from French for the booksellers, and rapidly became a distinct force in American politics. He started a bookstore in Philadelphia, and when that place became inconveniently uncomfortable, he removed his business to New York, and returned to England in 1800.

We need not follow Cobbett into the bewilderingly numerous phases of his literary career, but it is peculiarly interesting to notice that by the year 1804 he was, in addition to his literary work, busily engaged in agricultural pursuits on a large scale at Botley, in Hampshire, which estate he purchased with the proceeds of his pen. In 1821 he started a seed-farm at Kensington, and in this year appeared what is, so far as we are concerned, his first important work, *The American Gardener*, which, with certain modifications, appeared under the title of *The English Gardener*, in 1829. This work, which was "published by the author, 183, Fleet Street, London," marks an era in the history of the gardening literature of this country. Cobbett was not only full of theory and of practical knowledge, but he possessed the then uncommon ability of writing on practical gardening in clear and vigorous English. His predecessors were, for the most part, either botanists who possessed only a rudimentary knowledge of gardening proper, or they were highly skilful gardeners, without the ability to express in a lucid manner their own operations. Every editor of a gardening paper, even at the present day, knows of the existence of this very trying anomaly on the part of some of their most valuable contributors—men whose knowledge is of the widest and most intimate description are often unable to adequately commit to paper details which to them are as simple as the proverbial A B C. The present writer could name at least one book by a distinguished writer on practical gardening which, after being entirely set up in type, had to be entirely re-written, and, therefore, re-set. In practical details there is not, it must be admitted, much room for brilliant writing, but that is no excuse for involved sentences or Johnsonian pomposity.

Cobbett had a very high opinion of himself in most things, and in nothing so much as the excellence and the purity of his mother tongue. Wherever one dips into *The English Gardener* it is the same, a clear, concise, and vigorous style, which is quite captivating. In many cases the instructions to be found in Cobbett's book are as applicable to-day as they were seventy odd years ago. The book, which is unpagged (but comprises about 400 pages), is divided into seven chapters, and the whole work is re-divided into 551 paragraphs, each of which deals with one particular subject. The author proceeds upon the assumption that the reader is wholly unacquainted with all the matters of which his book treats. "Experience," says Cobbett, "has taught me the necessity of proceeding in this way; for, when I have had to apply to books to be my teachers, I have invariably found that the authors proceeded upon the notion that the reader only wanted a little teaching; that he understood a great part of the subject, and only wanted information relative to that part which the author happened to think of the greatest importance. By looking on the reader as knowing nothing at all about the matter, the author is led to tell all that he knows. . . . I make no apology for the minuteness with

which I shall give my instructions, for my business is to teach that which I know, and those who want no teaching, do not want my book."

A curious anecdote is told of Lord Bacon in Tull's famous work on *Horse-hoeing*, to the effect that this great man, having made a vast collection of books on horticulture and agriculture had them one day all collected together, omitting not one, had the pile carried into the courtyard, and there set on fire, saying: "In all these books I find *no principles*; they can, therefore, be of no use to any man; he must get principles for himself, or he must go on till the elements have instructed him, and, in either case, he can stand in no need of books like these." The anecdote may probably be more fiction than fact, but it served Cobbett's purpose to "nail" the theory that when once the learner knows the reason for that which he does, he may be said to have learnt it, and not before. As to the manner of studying *The English Gardener*, the author advises the reader to begin by "reading it all through, from the beginning to the end, and not to stop here or there to learn one part of it at a time. If he were to do this three times over, it would only require the time frequently devoted to three or four volumes of a miserable novel." Mr. Cobbett's modesty is certainly not his least amazing quality, although his arguments are perfectly logical. The chief cause of failure, he contends, lies in omitting to carry out instructions in their entirety. He again quotes Mr. Tull, who very justly complained that those who condemned his scheme, and asserted that they had tried it, and found it to fail, always omitted some one thing, which omission rendered the other operations abortive. "Their great error is in the mis-use of the word *IT*—they say they have tried *IT*! they have tried something, to be sure; but they have not tried my scheme."

Cobbett severely condemns the practice of "placing the kitchen-garden in some out-of-the-way place, at a distance from the mansion-house, as if it were a mere necessary evil, and unworthy of being viewed by the owner." The author backs up his complaint with the unanswerable enquiry—"In the time of fruiting, where shall we find anything much more beautiful to behold than a tree loaded with Cherries, Peaches, or Apricots, but particularly the two latter?" And he then further silences objections with this remark—"It is curious enough that people decorate their chimney-pieces with imitations of these beautiful fruits, while they seem to think nothing at all of the originals hanging upon the tree, with all the elegant accompaniments of flourishing branches, buds, and leaves." The position "must absolutely be open to the south; well-sheltered, if it can be, from the north and from the east; but open to the south it must be, or you can have neither fine wall-fruit, nor early crops of garden-plants." He insists that a slope is exceedingly desirable; "but to have the whole of a garden upon a slope is by no means desirable; for, however gentle the slope may be, the water will run off, and, in certain cases, it is absolutely necessary that the water should not run away, but have time to soak gently into the ground. I have had great opportunity of acquiring knowledge in this respect. Part of my ground at Kensington forms a very gentle slope. The soil of this slope is as good, both at the top and bottom, as any ground in the world; but I have always perceived, that seeds never rise there with the same alacrity and the same vigour as they do upon the level part, though

the soil there is much inferior." Cobbett instances the kitchen garden of Mr. Henry Drummond, at Albury, Surrey, as being, in his opinion, "nearly perfection," and as "well worth the trouble and expense of a long journey, to any person who has a taste that way."

We have no space in which to follow Cobbett in his other sections, which deal respectively with soil, enclosing, and laying-out of kitchen gardens, but it is interesting to note that the theories which he held are substantially those which are held to-day. Dissertations on hot-beds and greenhouses, on propagation and cultivation in general, on seeds, transplanting, and so forth, in none of which is there apparently much scope for "incidental" writing, but in all of which Cobbett is entirely original and frequently entertaining. He exposes many old-fashioned theories, notably, that in which it is insisted that the ground "grows tired" in time of the same plant; in support of this he not only refers to Mr. Tull, but instances a neighbour of his, who, and whose father, had for upwards of fifty successive years grown Peas in the same border, which Peas, he says, "were as fine, and as full bearing, as any that I ever saw in England."

The fifth, sixth, and seventh chapters form the body of the work, and deal respectively with kitchen-plants and fruits, each section being arranged alphabetically, and with full particulars as to propagation, cultivation, and so forth, often interspersed with Cobbettisms which greatly enliven what cannot help being in a general way somewhat heavy reading. It is not easy to believe that Cobbett could have had practical experience of all the many plants and subjects which he writes about in this book; it is quite certain that his knowledge of gardening was extensive, and his powers of observation and of memory abnormally keen; and where he lacked experience he appears to have assimilated the teaching of others in a truly wonderful manner. *The English Gardener* is on the whole a most interesting book, full of sound practical teaching, and it is one of the few books of its kind which would well bear reprinting, not as a relic of antiquity, but as a practical guide to gardening. *W. Roberts.*

NITRATES IN THE SOIL.

As soil fertility is of so much importance to horticulturists, and as the productiveness of a soil is directly proportionate to the amount of nitrates which it contains, and the facilities or favourable conditions presented for the conversion of organic nitrogen into ammonia and nitrates, the subject of nitrification becomes one of intense interest to all cultivators of the soil.

Nitre or saltpetre is a compound of nitrogen, which represents the form of combination in which nitrogen must be in order that plants may use it as food.

The organic nitrogen of the soil, called its inherent fertility, as well as that contained in such fertilising matters as stable or yard-manure, dried blood, fish scraps, rape-cake, vegetable and animal-refuse, &c., is not in a condition to serve as plant-food. To become available it must be converted first into ammonia and then into nitric acid.

All nitrates are formed in the soil through the agency of small microbes or living organisms called bacteria, which require certain conditions for their proper growth and development. These requirements may thus be briefly stated: air or oxygen, a due amount of moisture, a proper temperature, that ranging from 95° to 100° Fahr. being considered the best; phosphates and other ash ingredients of plants, a mild alkali, such as carbonate of lime (chalk);

and organic matter (humus) containing nitrogen. Shade is favourable to soil nitrification.

The germs themselves are in greater or less numbers in all cultivated soils, and in order for a soil to furnish the conditions necessary, as enumerated above, it must be loose and porous, so as to admit atmospheric air freely; it must be well drained, and have good capillary action, so that at all seasons it will, as nearly as possible, contain that amount of moisture about it which is present when ground digs well, as this is found to be the degree of moisture most desirable. The soil should have plenty of organic matter (humus) within it to furnish nitrogen, and favourably influence the supply of water. For this reason horticulturists find leaf-mould, pasture-turf soils, and peat soils so beneficial for plant-growing.

Soils deficient in the nitric ferment germs or bacteria are barren, while those which furnish conditions favourable for nitrification, such as those enumerated above, are always fertile.

The total quantity of nitrates formed in a fertile soil is considerable. Experiments have shown that they may range from 75 lb. per acre in an unmanured soil, to about 125 lb. per acre in a soil to which farm-yard manure has recently been applied.

But it may be well to note that the whole of this nitrogen is not available to our ordinary cultivated crops, for the reason that many of them only assimilate the spring or early summer nitrates, the principal growth and power of assimilation having ceased by the month of July.

Vegetable crops, such as Cabbage, Beet, Onions, Turnips, Carrots, Parsnips, Celery, &c., may still get hold of summer nitrates, but the nitrates produced in late autumn and winter are of little use, in so far as this applies to outdoor plants.

The spring nitrification of a soil alone is, as a rule, quite insufficient for the requirements of early-spring plants, hence the advisability of using some stimulating manure, if very early production of vegetables is desired. *J. J. Willis, Harpenden.*

PLANT NOTES.

GAZANIAS.

THE bright flowered *Gazania splendens* still finds a place in our flower gardens, although not to the extent it did formerly when employed in massing and as an edging plant. Of late years *Gazania nivea* has been introduced by the firm of Bredemeyer in Pallanza. The species was discovered in Bechuanaland and Griqualand by Dr. Burchell between the years 1811 and 1814, and named by Sander in the *Linnæa* as *G. pygmæa*. This species is a useful, effective plant, and for this reason was much employed in the flower-garden. One of the first to cross *G. splendens* with *G. pygmæa* was M. Lemoine, who used the first-named as the pollen parent. The result was *G. nivea latiflora*, a very large flower with rounded white-yellow rays, whose underside was striped with violet. The disc is dark yellow.

M. M. Dammann & Co., Naples, were fortunate in obtaining crosses with *G. stenophylla* as one of the parents; the results being plants with blossoms that vary in tint from milk-white to ochre yellow, and of a size much greater than *G. splendens*, and whose duration is from the spring to the end of the summer. The plants reach a height of 6 to 8 inches. The leaves are narrow, smooth at the edges, and occasionally divided; the upper side shining green, and the reverse side silvery, white with a green mid-rib.

The varieties are Bianca, sulphur yellow, changing to white with a slight violet spot at the base of the rays; Blondine, light chamois at the base, dark orange reverse side, white with dark violet stripe in the middle of each ray, and 3 to 3½ inches in diameter; Diana, flowers at the base chrome yellow, changing to yellowish-white at the tips of the rays, at whose base is a sharply outlined black patch; Nora, cream white with rosy lilac tips, and at the base of the rays sulphur yellow, and at the base a patch similar to that seen in the last named. *Wiener Illustrierte Garten Zeitung.*

THE CULTURE OF CATTLEYAS.*

(Concluded from p. 196.)

GENERAL MANAGEMENT.—I now draw your attention to the after-treatment, or the general management of the *Cattleya* house, and to my mind, this is where we find the greatest difficulty in their cultivation.

Man (always interfering with something which he does not understand) lifts his puny hand to amend, or thwart the works of Nature, and huddles together in one little house, as slaves and prisoners, the free children of Nature, denizens of climes and conditions as diverse as chalk and cheese, and says to them, "Come now, dwell with us and be good, that we may enjoy your beauty."

In our *Cattleya*-house, we have plants from different parts and localities, which vary much in every respect; some are from the trees of high and lofty positions where they get much light and air, and less moisture; some are from trees of lower regions where of necessity light and air must be less, and moisture greater; others are found on rocks up the mountain side, exposed to the rays of the tropical sun and the blasts of trade-winds. A knowledge of the different habits of the various species is essential to the cultivation, in order that he may as far as possible, suit his treatment to their several necessities. But this, of course, can only be done in a very limited manner.

Then again, we have plants which flower at different times of the year, in fact at all seasons of the year; and some rest after they have made their growth, such as *Trianae*, *Mossiae*, *Schroderæ*, *Percivaliana*, &c.; while others, such as *Warneri*, *gigas*, *guttata*, *Schofieldiana*, and a lot more, flower on the new growth as soon as it is complete, and rest after they have finished their season's work instead of in the middle of it. In our artificial treatment we endeavour to get them all to rest in the autumn and winter months, and by this treatment the last-named batch will require less care and less water at the roots, through the winter, than will the former, which have to maintain their flowers in embryo during the resting season. Again, they will of necessity start into growth again at different periods of the first half of the year, from Christmas to Midsummer. *C. Warneri*, being the earliest of this batch, will start first, and if great care be not taken in the management of the house and of this particular species, it will start its growth by Christmas, hence the short days and lack of light will militate largely against the solidity and flowering quality of its growth. Therefore the house should be kept as cool and airy as possible through December and January (compatible with the well being of those that are coming into flower) so as to prevent the growing of any until well into February, when we get longer days and more sunlight for their development. From this time the temperature and atmospheric moisture should be increased, and each section as they start into growth should have an increase of moisture at the roots. All *Cattleyas*, in their growing season, require an abundant supply of moisture both at the roots and in the atmosphere, and all the light and air that can be given with safety, avoiding scorching sun and cold draughts. The management of the *Cattleya*-house during the summer is not so difficult as during the winter, but even this should be attended to with great care, and be done under the personal supervision of one who understands the habits and requirements of each species.

Sometimes damage is done especially to late growing species by water lodging in the young growths, and thus causing them to decay. This to a great extent may be avoided by cutting the scaly sheath that envelopes the young bulb with a sharp knife, and turning it back so that no water can lodge there. This can be done without any injury to the plants. The syringe may be used with advantage during the spring and summer, but through the autumn and winter should be avoided.

It is useless to expect *Cattleyas* to flower satisfactorily unless they are well rooted, and have developed strong, well-ripened pseudo-bulbs. And even then it is not certain that they will do so, for I have found a few cases where, either through my mismanagement or ignorance of their requirements, or from some internal obstinacy on their own part, some *Cattleyas* have absolutely refused to flower, although healthy and strong.

INSECTS.

In the insect-world are to be found the enemies of *Cattleyas*, as well as of all other plants; but these plants cannot be regarded as dirty ones. If the atmosphere is allowed to become dry for any length of time, black and yellow thrip will be likely to make their appearance. These in minor cases should be washed off with warm soapy water, or any other insecticide. If the house should be affected badly, I should recommend a thorough steaming with tobacco-juice; this will be found very effectual, and will not damage the plants. But those in bloom should be removed to another house, if you wish to preserve the flowers. My mode of steaming is this. Put the tobacco-juice into any flat-bottomed vessel, such as an old milk-pan, or a galvanised tub, such as is often used for washing purposes. The liquid should not be more than from 2 to 3 inches deep in the vessel. Then have two or three ordinary fire-bricks put into the stovehole-fire until they are red-hot, place the vessel in the middle of the house, put the red-hot bricks into the liquid, and you will soon have the house filled with steam that will destroy the thrips, but will not injure the most delicate growth.

* Read before the Members of the Devon and Exeter Gardeners' Association, recently, by Mr. George Lee, gardener to Miss Lavers, Upton Leigh, Torquay.

Sometimes white or brown scale will attack Cattleyas. This should be carefully watched for, and as carefully washed off with soapy water, using an old tooth-brush, or any other article that may be found most convenient. Another rather serious enemy to this class of plant is what is known among Orchid-growers as the Cattleya-maggot. Fortunately, the pest is not very plentiful, and where it is understood and dealt with rightly, it is not difficult to get rid of. But if through ignorance or neglect it is allowed to take its course, it will soon play havoc with the Cattleyas.

It is an ugly little dingy-coloured fly, not so large as a common house fly, which will flit about among the plants through May, June, and July, lighting upon the young and fleshy points of any root that may be pushing its nose out over the rim of the pot, or through the side of the basket. It will puncture a tiny hole with its sharp bill-like proboscis, and deposit an egg in the hole, from which (in course of time) will emerge a tiny grub-like insect; when full grown it is not so large as a common ant. But as soon as the larva is hatched, the roots show signs of something wrong, ceases to grow forward, changes to a dark brown colour, and forms tuberous enlargement just around the insect. The remedy is a simple one; the fly does not live more than a few months, but they should be caught and killed as much as possible, and all the affected roots should be cut off and

the other is Lawrenciana, remarkable for its dark but brilliant colours. Each of these will often remain in bloom until midsummer.

In May, another fine old species will make its appearance, "C. Warneri," sometimes misnamed "labiata," introduced from Brazil in 1862; this species is not so well known, or so well grown as it deserves to be. It is the earliest of the summer-flowering kinds, and the form and colouring of its bloom are so striking that no collection of Cattleyas would be complete without it, and it flowers from the middle of May to the end of July.

Not quite so early to flower, but falling in with the foregoing about the end of May, we have another old and well-known species, "C. Mossia," introduced from Venezuela in 1836; this is too well known to need a description, but will help to keep the house gay from the end of May to the end of July or even into August.

Now we come to another, which may be termed the species of the genus, "C. gigas," introduced to this country from Colombia in 1872; although, according to Professor Reichenbach, it was first discovered in 1848 by Warszewicz, whose name it bore for years, until, in consequence of the enormous size of its flowers, it became known in English gardens as the giant, or "gigas." This, with four other species—namely, C. Hardyana, Sanderiana, Dowiana, and

display with the flowers, but by keeping the house moderately cool, and the atmosphere dry, and the flowers free from drops of water, they will last much longer in perfection; sometimes, nay, often, too long, for the benefit of the plants. Carrying the flowers to the very end has a tendency to weaken all Cattleyas, therefore the careful cultivator will see it is best to cut them from all weak and valuable plants long before they show any signs of decay.

In Orchid growing, more than in that of any other class of plant, it is impossible to work by hard-and-fast rules. The structure, condition, and situation of the houses must be considered, as well as other factors, in the shape of convenience, space, labour, &c. And the careful gardener, who has a soul for the beautiful in his profession, and an aim bent on success, will take these things into consideration, and will mould his actions, as nearly as he can, upon the principle of common sense, in the peculiar circumstances in which he finds himself, taking copious notes as he proceeds. At the right time, for the purpose, he will stand back (mentally at any rate), as an artist does, to view his work; and where failure is apparent, he will seek to amend his ways—but where success has crowned his efforts, he will thankfully take courage, and be wise enough to leave well alone.

SEED-DISPERSION.

In the interesting article on the plants observed near Jeur in the Deccan, by Mr. Marshall Woodrow, at the time of the recent eclipse of the sun (see p. 161), mention was made of a singular grass—*Aristida setacea*. The awns, it appears, have three divisions, and these get interlaced into the form of a ball, and are blown, with the seeds attached to them, from place to place, thus ensuring the distribution of the seed. Our illustration (fig. 79), taken from a photograph kindly sent by Mr. Woodrow, shows the way in which this beneficent arrangement is carried out.

POUCH-BEARING AND OTHER FERN VARIATIONS.

IN connection with the enormous number of varietal sports which Ferns, especially our British species, afford in the wild state and under cultivation, there are certain peculiarities which are deserving of especial notice which may afford some clues to that under differentiation which distinguishes species from mere varieties, and genera from one another. At present we are in ignorance regarding the influences which induce sports, and it is impossible for us, therefore, to indicate any specific theoretical lines; and all we can do is to classify and record them, in the hope that the laws which rule them may some day be revealed—just as a heterogeneous mass of statistics often discloses curves and coincidences from which quite unexpected information is obtained. One of the most singular forms of eccentric variation is that in which the frond or leaf, instead of tapering more or less to a point, abruptly terminates in a pouch, from which the central rachis or rib projects nakedly, and tapers off into a sort of thorn, or the pouch may be absent, and the frond or leaf apparently as squarely cut off as with a pair of scissors.

Odd, however, as this "sport" is, there are marked examples found in Ferns; moreover, it is an established characteristic of the leaves of the Tulip-tree (*Liriodendron tulipiferum*), and in a modified form in some varieties of Croton. In British Ferns we have *Lastrea montana truncata*, in which the type of the fronds, as well as the side divisions or pinnæ, are so characterised, the whole frond having an artificial appearance, with its square ends. In *Scolopendrium vulgare* vars. *periferens*, *cornutum*, and *bicornutum*, there are numerous forms of this singular character, *periferens* bearing large or small pouches behind the frond; *bicornutum*, sometimes bifid, whence the name, one in front of the frond; and the various forms of *cornutum*, having the end of the frond rounded abruptly off, and the midrib projecting from the front or the back, according to the particular variety, but never indiscriminately on one plant. The best form of this last class is one found by Mr. S. Wollaston, son of Mr. G. B. Wollaston, one of our greatest authorities on British Ferns. This is of full normal size, with the robust fronds neatly rounded off, the midrib projecting from the centre of the arc as a blunt hook; on the back the sori radiate exactly like the figures of a dial, whence the name of S. v.

FIG. 79.—AWNS OF *ARISTIDA SETACEA* FORMING A BALL, BY MEANS OF WHICH THE SEEDS ARE DISPERSED BY THE WIND.

burnt at the first sign of the larva's existence. By careful attention, the house can soon be cleared of this foreign intruder.

SELECTION OF SPECIES.

I will give a list of those species which, from my experience, I consider to be the best and most useful to keep up a succession of flowers all the year through, but I could not guarantee this with one plant of each sort; but half-a-dozen of each, under proper treatment, would ensure a goodly display of these grand flowers from one end of the year to the other.

To begin with the new year, we have one, though not so large as some of the species, yet nevertheless must rank high among the choicest and most useful of the genus, *Percivaliana*, introduced to commerce about twelve years ago from Venezuela, and named in honour of Mr. R. P. Percival, of Birkdale, Southport. If the earliest plants of these have been subjected to a gentle forcing through November and December, they will be in full flower a week or two before the new year commences; and if the remainder of the batch be brought on in close succession, they will carry us on to the end of March.

Then, long before this, we have the early bloom of another old and well-known and much admired species, with a lot of beautiful varieties, *C. Trianae*, introduced from Columbia in 1865. This is a beautiful and useful spring-flowering species, which will carry us on from February to May, or even beyond. And there are two other species that bloom about the same time, both of recent introduction, but of such value that I cannot omit the mention of them in this list. One is *Schroderae*, remarkable for its delicate colouring and sweet fragrance;

auraea—undoubtedly forms the grandest group of plants that can be found in cultivation. They form the five best varieties or species of the *gigas* group. The combination of colouring is so curious, and yet so beautiful, so bold and bright, yet so delicate; the massive grandeur of their flowers, often 10 inches across, is so conspicuous when mixed with other flowering plants, that it defies description, and has no equal among the occupants of our plant-houses.

This group may be had in flower from the middle of June to the end of October, while *bicolor* and *Loddigesii* will add a pleasing variety during August and September. As the earliest of the tall-growing section, to be followed by a splendid set of the same section, such as *guttata*, *granulosa*, *Schofieldiana*, and *Boweringiana*; the last named is of recent introduction from Central America, and of great beauty. They are all autumn-flowering, and will be gay until Christmas.

The last I have to mention is second only to the *gigas* group—the true old "C. labiata," Swainson's first discovery of eighty years ago, but which has been re-introduced, and written and talked so much about these last three or four years. It is undoubtedly the best winter-flowering Cattleya, and will keep the house gay from November to January, when *Percivaliana* will take up the strain, and commence the new circle again.

Just a word about the flowers. The atmosphere of the house in which the Cattleyas are grown is much too moist for the flowers to remain long in perfection; therefore, where there is a good collection of Orchids, there should be a house set apart into which they can be removed when in flower. By this arrangement you are not only able to make a better

cornuto radiosorum has been suggested. As spores are produced in myriads, sowings have been made by Mr. Wollaston and myself; but, singular to relate, purely normal plants have resulted. On the other hand, and this brings us to another of the facts I wish to record, this truncate character seems to be usually accompanied by added reproductive vigour, forming precisely the converse case to the plumose varieties, where excess of foliaceousness renders them more or less barren. In my fernery I find *S. v. paraferens* and *bicornutum* constantly springing up in the crevices as chance seedlings, and one of these has gone a step further and developed two pockets on the basal lobes as a constant feature. In a wild state, this form (*paraferens*) is recorded by Col. Jones as existing in quantities, being, indeed, the prevalent form in a wood near Portishead, Gloucestershire, which, of course, points to the same conclusion as the numerous chance seedlings in my fernery. This feature, furthermore, is so fixed in the strain, that some successful crosses have been effected, one conglomerate form raised by Mr. E. J. Lowe having little pockets and thorns on all the numerous ramifications of the other ramose parental variety. In the case of *L. montana truncata*, which belongs to a species difficult to raise from spores, there are no instances of chance seedlings under culture; on the other hand, a very large number of wild examples have been found in widely-separated localities. Mr. G. B. Wollaston has found it repeatedly in Kent and elsewhere, but I have recently found some examples in different parts of Scotland; and while hunting in the English lake districts, one of our party found a good example, and evoked the remark from an "old hand" that every beginner started there by finding *L. montana truncata*, the presumption being either that the normal form often sports independently, or that the spores of a few originals have produced widely-spread typical offspring, a supposition supported by the previously-cited cases in *Scolopendrium*. The Lady Fern has yielded one example, *A. f.-f. excurrens* and *Lastrea filix-mas* another; these, however, are rare.

In exotic Ferns, the curious little *Pteris serrulata Leyii* exemplifies the type; this originated under culture, and comes freely from chance-sown spores. Singularly variable as the Shield Ferns (*Polystichum*) are, I do not know of a distinct form of this type, the nearest approach being the various finds of *grandidens*, and some *truncatums*, properly so-called. None of these, however, have the abruptness or the pouch, and the thorn where present is only seen at the apex of the frond as a blunt projection. In brief, there are thus two species—*Lastrea montana* and *Scolopendrium vulgare*—of totally different habit and appearance, which are nevertheless subject to frequent sporting in this rare fashion, while in all the rest of the species the examples are very few. The same confined range of certain peculiar types is also exemplified in the "cruciate" varieties, in which the pinnae, or side-divisions of the fronds, are duplicated, or as Mr. E. F. Fox described it, the two basal pinnules of the pinnae are abnormally developed, the rest being aborted, the result being the formation of a series of crosses from bottom to top of the frond. This type is only seen in two species—*Athyrium filix-femina* and *Polystichum angulare*—as wild finds, though Mr. E. J. Lowe managed to transmit it by hybridisation to a form of *P. aculeatum*. In *Athyrium* we have first and foremost *A. f.-f. Victoriae*, where it is developed to the utmost. *A. f.-f. Fieldæ*, *Frizellæ*, and *proteum*, are modifications of it. These peculiar types of variation are, with few exceptions, such as the Tulip-tree and Crotons, confined to Ferns. This in itself is a curious fact, when it is considered that Ferns and their allies were certainly the progenitors of all other land-plants, that such marked tendencies in them should now so rarely crop up outside them. The tasselling of so many species of Ferns, and which has been found to characterise nearly all our British species, is still more markedly absent in other plants; the only instance to our knowledge of true cresting presenting itself curiously enough in *Asparagus plumosus*, popularly, though erroneously, called the

Asparagus Fern. The crested form of this has bunch tassels on all terminals in Fern fashion, the assumption of the Fern type being thus correlated with the power of varying still further on Fern lines. Fasciation, as seen in Lilac stems, *Celosias*, and many other cases, is probably akin to this phenomenon, but a study of Fern tassels shows the distinct difference that the multiplication of the special cell which leads to the formation of the tassel commences after the main and secondary, or even the tertiary rachides have made considerable growth as simple ones. It therefore represents an independent branching on their parts, and not as in cases of fasciation proper, a cohering together of originally numerous growths so as to form a fascies or bundle. In *Pteris serrulata* var. *Applebyana* the plant indeed apparently first perfects its fronds normally, no division at all appearing, but this done, the special cells commence to form dichotomous filaments, which finally produce large handsome tassels. One *Athyrium* in the writer's collection carries this cresting to the fifth degree in a perfectly symmetrical regular fashion, and it is certainly very wonderful to consider the subtlety and thoroughness of the influence therein which determines in every division a certain length of simple rachis and a multiplication of the apical cells at a precise and definite period of its extension. *Chas. T. Druery, F.L.S., V.M.H.*

FORESTRY.

DEGREES OF THINNING.

THE thinning of Fir woods, and those of Scots Fir in particular, becomes the more important the further north we go in the United Kingdom. Our Scotch brethren are particularly alive to the importance of keeping their woods sufficiently open to impart to individual trees that stoutness of stem which most effectually withstands the force of gales which sweep so frequently over the country; and if this condition were the only really important one, differences of opinion on the subject of thinning would be less frequent. But, as already mentioned, quality of timber ought to be of equal importance in the eyes of a good forester as the actual bulk of individual trees. While a great deal of home-grown Scots Fir may be converted into railway sleepers and other articles in which fine quality of timber is of little importance, there is still considerable scope for the utilisation of fine timber in buildings and other structures in rural districts. The majority of farmsteadings in Scotland are built and repaired with home-grown timber; but it is, nevertheless, a well-known fact, that the quality of a very large proportion of this timber falls far behind that of imported Canadian or Swedish timber. No doubt a great deal of the prejudice against the former arises from the unseasoned condition in which it is too often used; whereas, this fault is rarely if ever found in foreign timber.

But over and above this, it cannot be denied that the home-grown article is, generally speaking, of a far coarser and more knotty description than its foreign rival, although equally durable and resinous. The disadvantages of this knotty condition are familiar to every carpenter and builder, and owe their origin almost entirely to the system of thinning practised in the early life of the plantation in which the timber is grown. The Scotch method is based upon the principle of giving each tree in the plantation a sound constitution before it enters upon that struggle for existence which plays so important a part in biological history. The result of this method undoubtedly gives us a plantation with a large proportion of stout well-rooted trees, but the length of time which elapses before close order is arrived at enables the lower branches to attain a size which means ugly knots being left in the timber when they are finally killed off. The more scientific method employed by continental foresters avoids these knots by close planting at the outset, and leaving the trees to practically thin themselves, the forester simply removing what are no longer taking any active part in the growth of the wood.

Coarse knots on the lower part of the stem are thus impossible, as the branches are killed off when quite small, but a large number of trees become weak and spindly in the process, and great care must be exercised to prevent gaps being made in the plantation when weeding out suppressed trees, or the wind soon plays havoc with the crop.

In large and well-organised forests, young and middle-aged plantations are always sheltered from prevailing winds by older parts of the wood, and at the time any particular section has to bear in its turn the force of the wind unprotected, it is composed of matured trees which are shortly to fall before the axe. In the ordinary plantations of Great Britain, if an organised attempt is made to protect them from wind in this way, and the forester relies more upon the root-hold his trees have on the soil, than upon measures which seek to avoid the full force of the wind being exerted upon the young and immature plantations. Herein may be found the rock upon which Continental and British foresters are apt to split, for the latter know only too well that well-drawn-up woods, similar to those found in Germany and other parts, are apt to suffer greatly in severe gales, exposed as they frequently are to its full force. But while both systems have something to be said in their favour, the adoption of one in preference to the other should depend upon surrounding circumstances. In sheltered situations the Continental method can be safely adopted in this country, and with equally good results. In exposed sites, and thin soils, on the other hand, small plantations of Scots Fir are probably best thinned on the lines usually adopted by Scotch foresters, although the quality of the timber so produced may not be all that can be desired. *A. C. Forbes.*

(To be continued.)

MELTON CONSTABLE.

AT Fulmodestone Wood we saw what is probably the most magnificent collection of Coniferæ in England. Rain was then falling heavily, and the long grass was completely saturated; but the sight of such a succession of noble trees, perfect in shape and form, and some of them throwing out boughs of such length as to make an approach to the trunk a somewhat difficult operation, led us to forget any temporary discomfort resulting from the disagreeable weather. The planting of these trees was undertaken merely from love of arboriculture, and not with any idea of reaping profit. The wood is 211 acres in extent, and is well drained, and the Coniferæ are protected by a pre-existing crop of Larch and other timber trees, which have been felled from time to time to promote their growth without reducing their protection. Planting has been going on gradually ever since 1851, when the earliest of the Coniferæ were placed here. Some that were planted not more than twenty-two years ago have reached a good height already, and in almost every instance the growth has been very rapid. A blown Silver Fir, which we saw on entering the wood, was measured, and was computed to contain 462 cubic feet of timber. But that is only by way of parenthesis. Pursuing our way through the wood we come up to two specimens of *Abies Webbiana* planted in 1851, and one of which has a quarter girth of 18 inches; *A. nobilis*, 21 inches, over 70 feet high; *Sequoia gigantea*, planted in 1857, 26½ inches, over 100 feet high; *Thuja gigantea*, 9 inches, 50 feet high; do., 15½ inches; do., 15 inches, 70 feet high; *Picea canadensis* (Hemlock Spruce), 9 inches; *Pseudotsuga Douglasii* (American Red Fir), 16½ inches, about 80 feet high; do., 20 inches; do., 20½ inches (all planted in 1852); *Tsuga* (Californian Hemlock Spruce), 14 inches, 80 feet high; do., 14½ inches, 90 feet high (both planted in the early "fifties," and very fine specimens). There is a group of these majestic trees which we named the "Albert group." A fine avenue of *Abies nobilis* claims brief attention, and then an avenue of Douglas Firs (Rocky Mountain type), planted twenty-two years ago; but all the larger trees of this species were planted in 1852, as already suggested. A close belt of Coniferæ on an exposed side of the

wood has created some difficulty for Mr. Munro. Formerly it was a sort of copse, which had to be cut down periodically, and when that was done, it left the main part of the wood open to injury. So the Hazel was cleared out, and *nobilis*, *Douglasii*, *Lawsoniana*, and others were planted in pretty closely with the view of giving permanent shelter. Now, however, they have grown so well, that Mr. Munro does not wish to part with any of them, and does not know which to sacrifice. Some of the *A. nobilis* were bought in pots at £5 apiece, and planted in 1851 or 1852. One of these has at present a quarter girth of 19¾ inches, and is 95 feet high. As regards the *Pseudo-tsuga Douglasii*, one of them is known to have grown up 6 feet 2 inches in two years. The only specimen of *Pinus Lambertiana*, the tallest of Pines, has a quarter girth of 16¾ inches; it was planted in 1851. This species does not thrive here. Two very beautiful trees standing together, and both planted in 1861, engrossed attention for some minutes. The one is *Abies Lowi*, and the other *A. grandis*. The latter is 17½ inches quarter girth, and 90 feet high; and the former 18½ inches

creased by sowing the small offshoot-corms, which, when the plants are healthy, are produced in plenty, but are more safe left in the pots or open soil than lifted and stored, as they are apt to perish by dry-rot. Seeds also may be collected and sown at the same time as those of the *Gladiolus*, good flowering corms being formed in two years in most cases.

Since the energetic hybridist, Lemoine, has taken it in hand, the *Montbretia* [or *Tritonia*, ED.] has almost developed into a florist's flower, the resulting varieties being of all shades of colour, from the palest yellow, through amber and orange, to blood-red and vermilion, while the hardiness of the hybrids exceed that of the species, so that in favoured spots, and in light soils, they may be left in the borders the winter through, and only disturbed when the herbaceous borders are rearranged in the spring, when the clumps may be divided and replanted.

They are all useful for cutting, a matter of some moment in this age, and like the *Gladiolus* and other Irises, the flowers open successively from the base to the point of the spike when placed in fresh water. The most distinct and useful kinds are "Eldorado,"

We are equally independent of the Dutch growers for our supply of Snowdrops, both single and double, these being grown in great quantities in the Eastern counties, in addition to the lovely little Siberian Squill (*Scilla sibirica*), and the Glory of the Snow (*Chionodoxa*), all of which are increased easily by selecting the largest and strongest bulbs or corms for use, and planting up all the rest to grow on till they attain to a flowering strength or size.

The handsome group of bulbous flowering plants known as the Tigridias are quite hardy in the south and west counties, and should be allowed to flower and form their seed-vessels; then they may be taken up, cleaned, and the bulbs divided, reserving the largest and thickest for planting up or for potting and lining up the small side-pieces, which, with generous treatment in regard to mulching and watering with liquid-manure during the growing period, will make very good flowering bulbs the first year. I may here note that when bedding these out on stiff wet soil, it is advisable that the bed be raised above the level of the surrounding ground, as this prevents the soil becoming too wet in the winter, when a few degrees of frost will be fatal. Also a little dry rubbish or cocoa-refuse spread to the depth of 2 or 3 inches over the bed, is useful as a protection from frost. Experience.

(To be continued.)

TULIPA PULCHELLA.

THIS, another of the series of little known plants re-introduced to Europe by Mr. Siehe, German Consul at Mersina in Asia Minor, which we have been enabled to figure during the last few months. *Tulipa pulchella* is a plant of dwarf growth, indigenous to the alpine and sub-alpine regions of the Cilician Taurus, where it is found growing among loose stones. The flowers are of a deep rose colour, and possess a yellow spot of a star-like shape at the bottom. Our illustration shows the plant of half its natural size.

THE LOST ONION TRADE.

Is it possible that our market-growers and farmers are allowing the French farmers of Brittany to monopolise the sale of this famous esculent in England? This is a question that came to my mind when reading a very forcible article in the *Daily Mail* of February 12, with the heading, "In Search of Trade: A Lesson. 'Made in France' this time." It says, "The presence of the forty-seven Breton Onion hawkers on the *Channel Queen*, wrecked off Guernsey recently, draws attention to a business that is increasing by leaps and bounds, to the detriment of the British farmer." Among other particulars, it stated that from 15,000 to 20,000 French [?] peasants visit British annually with the object of selling Onions grown upon farms in the Departments of Finistère, Cotes du Nord and Ile et Vilaine." Originally these Onions were sent wholesale to Covent Garden, but the prices realised not being satisfactory to the growers, other means had to be resorted to, to make the trade remunerative. This took the form of chartering two sailing vessels about to return to North Wales, which they loaded with some of the best of their produce, about a dozen farm hands and two or three sons of the shippers accompanying the cargo, which was disposed of by hawking retail, at a clear profit of over 50 per cent. above that obtained previously at wholesale rates. In the ensuing summer shipments were made to Cardiff and Bristol, and similarly disposed of. This start was made some eight or ten years since. "Year after year other districts have been exploited, until to-day there are French Onion depôts in most of our ports and large inland towns. Lately the growers have formed several limited companies, under whose fostering care the industry is likely to be still further increased upon the same lines." Surely if Onions can be grown in the North of France and be brought here and sold by the growers at remunerative prices, our English farmers in the southern counties should be able to compete with them. C. Herrin, *Dropmore*.

FIG. 80.—TULIPA PULCHELLA.

(Colours of the flower deep rose, with a white star at the bottom of the cup.)

quarter girth, and 80 feet high. Probably the largest *nobilis*—at least, the largest noticed on our tour through the wood—is 26 inches quarter girth, and is about 75 feet high. This was one of the plants bought in pots at £5 each. An *A. Pinsapo* measured 11 inches quarter girth, and has a height of 42 feet. Only one specimen of *Libocedrus decurrens* was observed: its quarter girth is 14 inches. Amongst the other specimens noted were—*Sequoia* or *Taxodium sempervirens*, 14 inches, 65 feet high; *Cupressus Lawsoniana*, 15 inches, 75 feet high; a group of *Thuja Lobbi*, nearly 90 feet high, with a girth of from 15½ inches to 16 inches; *Cedrus Deodara*, 11½ inches, 75 feet high; *Thujopsis borealis*, a very fine specimen, very graceful and symmetrical; and *Cryptomeria japonica*, also very fine. All the underwood hereabouts was felled about ten years ago, and the younger *Coniferae* were planted wherever a suitable spot was found. *Transactions of the English Arboricultural Society*.

METHODS OF PROPAGATION.

(Continued from p. 165.)

BULBOUS FLOWERING PLANTS.—*Montbretias*, *Tritonias*, *Watsonias*, *Ixias*, and *Sparaxis*, as well as the brilliant little *Anomatheca*, may all be rapidly in-

Etoile de Feu, *Fantaisie*, *Feu d'Artifice*, and *Transcendant*; while in the variety named *crocsmiflora*, the delight of all florists, has been attained, namely, a double form, which its fortunate raiser foretells, is to become the progenitor of a new race of double flowers sure to come into fashion!

The *Crocus*, another well-known cormous plant, has for many decades been grown for the trade in the rich, light soil of Lincolnshire and the adjoining counties, where the favourite early-flowering yellow is cultivated and sold by the million; and the so-called Scotch, and a striped form named *C. versicolor*, in less quantities. The increase of these is a simple matter, each corm when it flowers dies off, and leaves a numerous progeny of small cormlets at the base of the leaves; some of these attain to flowering strength, but the majority are only serviceable to quarter up, and grow on for the next season.

The bulbous *Iris* tribe, commonly called English, Spanish, and Persian *Iris*, may all be propagated from the small side bulblets, which may be broken off at the time they are lifted and planted up in September or October. These should not be allowed to flower the first year, but by the second season they will have made full-sized bulbs which will be fit to sell, or plant up for flowering the following season.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Potato Planting.—The first three weeks of April afford the best period for planting the main crop of Potatoes, and in deeply-dug light soils the sets may be dibbled in 6 inches deep, affording a space of 30 inches between the rows, and 10 inches from set to set. [Or they may set in shallow basins excavated with a big draw-hoe just as quickly, and the tuber touching the soil everywhere, of course care being taken to cover them with soil with the same tool. Ed.] Wet heavy land should be manured, dug, and planted at the same time, the sets being laid on the manure at from 10 to 12 inches apart, and at 30 inches from row to row. If the sets are rather large, they may be cut in halves, each half having not less than three strong buds. Smaller sets should not be cut, and have only a few of the eyes removed. Any crowding of the shaws result in a loss of weight in the crop. A change of seed should be obtained every third year.

Kidney Beans.—A sowing may now be made on light soil on a south border, and means taken to protect the plants when above-ground, from injury by frost. Another sowing may be made about April 30. Beans should be sown in drills 2 inches deep, running north and south, and the drills may be 1½ foot apart for the dwarf varieties, to 2 or 2½ feet for Canadian Wonder. The new climbing French Bean and the white-podded Butter-beans may be sown at the end of the month, and both varieties should occupy a warm site.

Cabbage.—Early-sown Cabbage plants for summer use may now be planted, and the plantations of August-sown Cabbage moulded up with the hoe, drawing the soil up to the lower pair of leaves. A sowing may be now made for providing heads for cutting in early autumn. Couve Tronchuda may now be sown.

Carrots.—The seeds for the main crop should now be got into the ground without delay. The Carrot-quarter should have been plentifully dressed with decayed manure, lime, and, if wireworm be present, slightly with gas-lime. It should now be dug over half a spit deep and well tilled, and then roughly raked, to render it level, and take off the biggest stones, &c., and be trodden evenly all over, or rolled with a wooden roller. The surface should then be finely raked and made smooth, and drills drawn 1 inch deep and 9 inches apart. The seeds, if new, should be sown thinly, after mixing them with twice their bulk of damp sand, and be covered with the fine soil to the depth of half an inch. If wireworm and the Carrot-maggot infest the soil, the best method is to sow Carrot-seed frequently at the end of the spring and in the early summer months, choosing varieties with short roots, such as Dutch Horn, Carentan, &c. Late sowings of Carrots are not so subject to be infested as early sowings.

Vegetable Marrows.—Sow seeds singly in small flower-pots, and place in a warm frame, so as to have plants for placing under hard-lights or frames in May. These early sowings should always be provided with slight hot-beds of stable-dung, or dung and tree-leaves, placed beneath the plants.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Bulbs which have been Forced.—Instead of the gardener throwing these bulbs to the rubbish-heap, as is usually done, it is better to gradually harden them off, and afterwards plant them in spare ground till the foliage ripens naturally, and then clean, dry, and store them. Clumps of Lily of the Valley may be permanently planted on the north side of a wall. It will be three years before the buds that form on the roots that have flowered will themselves flower. Bulbs of Narcissus, Scillas, and Snowdrops should be stored till early autumn, and then planted wherever required in the garden or pleasure grounds.

Spiræas.—The varieties *astilboides*, *palmata*, and *japonica*, if they have been forced, should be similarly hardened off, and afterwards planted in the reserve garden in lines to recoup their energies, which they will do in two years, and be then again fit for being forced. A partially shady spot in moist loamy soil is best for them, and they will require frequent applications of water in hot weather. The same remarks apply to Solomon's Seal, *Dielytras*, and *Moutan* *Pæonies*, and many other subjects, both hardwooded and soft, which have been forced into flower.

Annuals for Bedding-out.—Seeds of Asters and Ten-week Stocks, and numerous species and varieties of

annuals, should be sown this month; the Asters and Stocks in boxes, or in frames, the seedlings to be pricked out when large enough. Slugs are very destructive amongst these plants, and every precaution must be taken against these creatures. The seed should be sown thinly, and pricking done, especially that of Stocks, when two true leaves are made, these plants being peculiarly liable to damp off when crowded together, and the air in the frame is close. Other annuals may be sown out-of-doors this month, due consideration being required in deciding upon their position in accordance with the heights of the various subjects, and the places they are intended to occupy. Choose a fine still day for the sowing operation, and when the ground is in good working order. If lines of plants are required, shallow drills should be drawn with a small hoe, and the seed sown thinly; and if broadcasted, let the ground be finely and evenly raked over, assuming that it has been manured and dug, scattering the seeds evenly over the surface, and raking them in, but do not leave the ground too fine on the surface, or it will become caked, and the young plants have a difficulty in coming through. Thin out as soon as the plants are large enough, if they are likely to become crowded. The chief secret in obtaining satisfactory results from annuals is to allow them space for full development.

Poppies.—For a brilliant display at a small cost the Poppy is the plant, par excellence, for the purpose, and the Shirley varieties, with their delicate shades of colour are very effective, and in consequence very popular. For brilliant colour the Danebrog Poppy is unsurpassed, the flowers being of a brilliant scarlet colour, and each petal has a white blotch which, when the flowers are fully expanded, forms a white cross on a scarlet ground, and from its similarity to the national colours of Denmark, it is usually known as the Danish Flag Poppy. *Papaver nudicaule*, the Iceland Poppy, belongs to a dwarfier class, and is very hardy, with flowers of white, yellow, and scarlet, excellent in the garden, and for table decoration in the cut state. Of other varieties, *P. Mephisto*, with fringed flowers; *P. glaucum* (the Tulip Poppy), flowers of a very deep scarlet; *P. bracteatum*, red with black blotches, very showy; *P. orientale*, deep scarlet with black blotches; *P. Snowdrift*, pure white with fringed petals; and *P. fimbriatum*, with, as its name implies, fringed flowers produced in great abundance, and in endless variety of colours, are among the finest. Never allow the Poppies to become crowded, or the flowering season will be short, and in case of a long spell of dry weather, the plants will entirely collapse.

General Work.—Continue the pricking-off of all kinds of bedding-plants. Propagate any plants of which the desired number is not yet obtained, such as *Lobelias*, *Coleus*, *Alternantheras*, *Iresines*, *Verbenas*, and *Mæmbranthemums*.

HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Pear-trees on Walls.—Before the flowers have time to expand, curtains of doubled fish-netting, canvas, frigi domo, or similar material should be hung in front of the trees; if fish-netting, it may remain in position day and night as long as protection from frost is needed, but the thicker materials must be withdrawn during daylight, which may easily be arranged by fastening the curtains to the top of the wall, with poles leaning against the wall under the coping at a distance of 10 feet apart, and at every second pole fastening a piece of stout string on the top of the wall, letting it come beneath the curtains to the bottom, and returning it on the other side to the top again, by means of which the coverings can be quickly drawn up or down.

Tomatos.—Provision should be made for filling vacant spaces on south walls with Tomato-plants, good returns in fruit being obtained from such plants in summers of average warmth. The Tomato may be grown successfully in the open quarters, training them on one to three stakes per plant. Plants for these purposes should be grown under glass until they are 2½ to 3 feet high with fruit set; and the plants will now require shifting into 6-inch pots, which will serve them till they are set out in the middle of May. Let them be afforded a rich light soil, such as light turfy-loam two-thirds, leaf-soil one-third; and keep each plant to one stem, the point of which should not be stopped, but all side-shoots as soon as they appear should be removed. Provide a minimum temperature of 55° by night, and let the day rise to 70° before air is afforded, and do not shade the plants at any time, but endeavour to keep them sturdy and short jointed. There is now a

great choice of varieties adapted for outside culture and only such as produce middling-sized fruit the ripens rapidly should be chosen, large or coarse growing varieties being almost worthless in ordinary summers.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

East Indian-house Temperatures.—April is an anxious month for the Orchid cultivator, as the changes in the weather are generally so numerous, it is next to impossible to keep constant the atmospheric conditions of the warm houer. Careful attention to shading, ventilation, and heating, however, will prevent very serious fluctuations. The hottest or East Indian-house needs the greatest care in these matters, because many of the plants are growing fast, and they must suffer no check. Little ventilation will be required in this house at present, except perhaps at noon, when the atmosphere is comparatively dry. On bright days, when the ventilators are open, and the sun becomes obscured by heavy clouds, close them at once. The blinds need not be worked up and down at every trifling change in the weather. Immediately the sun raises the temperature 6° or 7° drop the blinds, and keep them down on all very changeable days, but when there is no fear of the plants becoming scorched keep them up. At this season of the year scorching is very possible, and it is much safer to give too much shade rather than too little. It is difficult to shade properly the numerous species which grow in this house with special care to each group. Such species as the delicious *Calanthes*, *Thunias*, *Cycnoches*, *Catasetus*, *Mormodes*, *Cyrtopodiums*, *Dendrobium*, *Schomburgkia*, *Grammatophyllums*, *Epidendrum*, *Lælia rubescens*, *Vanda cærulescens*, *Brassavola venosa*, &c. should be placed at one end where they may receive the least shade, whilst *Phalænopsis*, *Aërides*, *Angræcums*, *Cypripediums*, *Bulbophyllums*, *Cirrhopetalums*, *Bolæas*, *Pecatoras*, *Zygopetalums*, *Vanda Sanderiana*, evergreen *Calanthes*, *Eulophiella*, &c. should be arranged at the opposite end where greater shade will prevent the foliage getting injured by sunshine.

The Cattleya-house.—The blinds on the Cattleya and intermediate-houses must be dropped whenever the leaves of the plants begin to feel warm to the hand, and they should remain down until the sun has passed off the roof, or in houses with a western aspect until it has lost most of its power. If lath blinds are in use in these two divisions, it is advisable to put extra shading under them for the protection of such plants as *Vandas* of the tricolor and *suavis* section, *Cypripediums*, *Oacidioms*, *Lycastes*, *Cymbidiums*, and the warmer section of *Masdevallias*. The bottom ventilators of these houses should be opened gradually when the outside temperature is above 45°, and wide open when 55°. In lofty houses, where the roof-ventilators are some distance from the plants, fresh air may be admitted freely without the use of the bottom ventilators.

Odontoglossum and Masdevallia-houses.—Drop the blinds on these houses immediately the sun touches the plants, and keep them down so long as the sun shines upon the roof. After several years of practical experience with the lattice-wood blinds, I find that for lean-to houses having a northern aspect the blinds are in every way satisfactory. For span-roof houses running north and south, with an east and west aspect, they are not quite so suitable; the extra light admitted through the blinds causes the foliage to become far more of a bronzy-red than is desirable, and I find the leaves so coloured do not last on the plants nearly so long. It is a good plan to lay some thin garden-mats upon the roof-glass under the lath blinds, the blinds being raised 6 or 8 inches above the roof, a cool current of air passes between them and the mats; by this means a very suitable temperature is maintained for the cool-growing *Odontoglossums* throughout the hot summer months. The blinds at the present time are let down immediately the sun begins to shine upon the roof, and as soon as it causes the inside temperature to ascend to 60° the mats are put on; they are taken off from the east side when the sun ceases to shine upon it, and from the west side about an hour before the sun goes down. Where the side lights allow the sun to shine upon the plants or their pots, they should be covered outside with thick tiffany or some other material. In giving air to these cool houses, the bottom ventilators should be slightly opened when the outside temperature is 40°, and widely opened when 50°. When the air is calm and mild, a little top air will be beneficial. Before damping down in the afternoon,

we close the top ventilators, leaving the bottom ones open in degree, according to the weather outside; by this means a suitable temperature is maintained throughout the night. In each division it is advisable to allow the atmosphere to fall 6° or 8° below saturation-point for several hours during the middle of the day; this will allow the plants to discharge all superfluous moisture, which, if retained, would prevent sound, durable growth.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Ivy-leaved Pelargoniums.—Young plants now rapidly growing, will be in need of close attention as regards shifting before they become root-bound. Let the points of the shoots be nipped occasionally to ensure bushy growth, as the plants are apt to run away thin if stopping be not resorted to. Spring-struck plants will require re-potting, and old plants, if growing in an intermediate-house, will now be coming into flower, and should be removed to a greenhouse or cool conservatory. These plants show to advantage when grown in baskets, three or more according to the size of the basket, being placed therein in good turfy loam, one sixth part decayed manure and some silver-sand. Such baskets should be lined with wood-moss, and when planted, they should be placed in an intermediate-house. The earlier-made shoots should be pegged-down, or otherwise secured to the sides of the basket, and have their points pinched out, the resulting shoots being allowed to hang unrestrained. These plants are valuable climbers, making a brilliant display if afforded a light, airy position.

Zonal Pelargoniums.—Plants, if strong and well-rooted in small pots, will soon begin to show flower if repotted in 5-inch pots, and stood close to the glass in a temperature of 50° to 55° by night, and 10° more than this by day, affording plenty of air on fine days. It is not too late to insert cuttings in order to raise plants for winter-flowering, but the shoots must be strong and sturdy. They can be placed in a warm house in a light position, where they will soon strike.

Caladiums.—Those that are growing freely may be finally repotted in light rich soil, which should not be made very firm; the plants requiring abundance of water when growing freely should have excellent drainage. They must be shaded from strong sunshine, otherwise all the light possible should be afforded to bring out the colours of the leaves.

Gloxinias.—Plants making free growth may be shifted into their flowering-pots in a compost of loam, dry cow-dung rubbed through a fine-meshed sieve, leaf mould, and a considerable proportion of silver-sand. Young seedlings may be pricked off directly they are fit to be handled into small pots or pans, and if late-flowering plants are desired seed may be sown.

Gesneras.—Shake the old soil from the earliest flowering species of these and start the tubers singly, or two or three of them together in one pot, in a Cucumber or Melon-pit. They will start quickly, but once the leaves commence to form the plants must have a position where the syringe cannot reach them, or the leaves will get rusty.

Tydeas.—Cuttings being now plentiful, they may be taken off and inserted in sandy peat, and the old plants thrown away. For large plants, insert the cuttings singly in small pots, and pinch the points from time to time; or place the cuttings thickly together in pans, and when they are growing strongly take off the tops and strike these, and throw the others away. These, if pinched once, make capital plants.

Thyracanthus rutilans, as it goes out of flower, may have the tops of the plants taken off and inserted in thumb-pots, placing them under a hand-glass in the propagating-house. The old plants may be cut back for the purpose of affording cuttings.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Figs in Glasshouses.—Fig-trees may be forthwith planted in new borders, and good all-round varieties for forcing are Brown Turkey and White Marselles, having middling-sized fruits, and Negro Largoas a large one; and of small-fruited varieties, of which there are many, Black Ischia, a good forcer, of a deep purple, and flesh of deep red; Brown Ischia, a free and excellent forcer; Pingo de Mel and Violette Sepor are among some of the best for house culture. Figs mostly grow to a large size, unless the root-runs are greatly circumscribed, and need a good deal trellis—10 feet in width and as much in height, is not too much per plant. In making a hole for the roots of

the plants, the soil should be taken out to a depth of 4 to 6 inches, and sufficiently wide for the roots to extend in all directions at full length. The trees to be planted should have been thoroughly cleaned with insecticide some time before. In planting, turn the roots out of the pots, take away the crocks, and remove by pricking and shaking the whole of the soil from the roots; slightly shorten the strongest of these, then place the plant in its place, lay out the roots straight, and work the soil between the roots, making all quite firm, the uppermost roots being then about 2 inches beneath the surface; afford a moderate amount of water, and fill in. The chief shoots may be temporarily fastened to the trellis in such a manner as to let the tree sink as the soil settles. The earliest fruits are often obtained from potted or tubbed trees; and any of these with ripening fruits will require a moderately dry, well-ventilated house, but in consideration of the second crop of fruits that will be taken from the trees, these points must not be carried to excess. In order to maintain a suitable atmosphere, the floor of the house, and other surfaces must be damped once, twice, or thrice a day, according to the aridity of the air. When all the ripe fruits have been gathered, a thorough syringing of the trees should take place, doing this in the early morning; and air should be afforded at that time by the top ventilators if weather permits. As Fig-trees absorb much moisture from the soil, liberal applications of water are required from time to time, and nothing favours the spread of red-spider so much as dryness at the root. When a second crop is set, afford weak manure occasionally, and alternate this with soot-water. If the bottom-heat materials are sinking, and likely to leave the pots above the surface in some measure, place fresh materials between the pots, not so much to afford heat at this date as to maintain equable conditions in the soil. To have fruits of the best flavour, they should be ripened on the tree; and indications of ripeness are the drooping of the fruit, exudation of honey from the eye, and the cracking of the skin. Gather the fruits when quite dry, and handle them tenderly, pinching the stalk off close to the wood, and at the same time bending the fruit slightly on one side. If to be sent to a distance, pack them like Strawberries.

Trees growing against Trellises, that were started in January, will need the removal of superfluous laterals, and the remaining shoots to be tied to the trellis, the points of these being pinched out in front of the fifth leaf. To bring two crops of Figs to perfection requires a long season of warmth; and the temperatures of the Fig-house from now onwards may range from 60° to 65° at night, 70° by day, with fire heat when it is dull, 85° with sun-heat, and 90° for a short time after closing the house in the afternoon. Afford air in the morning when 70° is reached, increasing the quantity at 75° and 80°, and leave on a little air all night when the weather is mild. Syringe the trees thoroughly once or twice a day. Should scale threaten to become troublesome, use soap-suds with a sponge; if soft-soap is used, it need not be stronger than 4 ozs. to the gallon. If mealy-bug be present, look for them diligently. Maintain the borders in a suitably moist condition.

THE APIARY.

By EXPERT.

Sections and Section-Racks.—These are likely to receive considerable attention this year, seeing that our brethren in America—where all the sections used are made—are just now exercising their judgment, and many of them advocating a new-style section without any "bee-way" cut in the wood, the said bee-way being provided by the divider or separator. One fortunate thing about the discussion is, that the outside measure of the section itself will remain the same. This is a comfort to all those who have a large number of racks made to take the ordinary-sized section. Some in America favour a section showing a larger surface of comb but less in thickness as being more attractive to purchasers. But in any alteration that may be introduced, the number of racks so in use here, made to take what may be called the standard size (4½ inches × 4½ inches) will have considerable weight with all who produce comb-honey in any quantity, before we alter sizes. The proposed new section will, it seems, be 4½ inches × 4½ inches without bee-ways cut in sides of wood. Those who have tried them say that the bee-wayless sections are better filled with honey to the edge of the wood all round. Think of that point, ye ambitious ones in our ranks, when working for the prize-taking sections another year! There is little doubt our pioneers in bee-supplies will have the new sections on hand ready for this season.

Handling Bees.—When the time comes for a thorough examination of hives again, it can be ascertained almost at a glance how matters stand within, and which combs contain brood, as well as making plain the presence of a queen, because the manner and behaviour of the bees are entirely different to those on frames, which are queenless and broodless. In examining frames of brood, be careful to first draw them an inch apart, and then steadily raise them but half out of the hive, just sufficient to ascertain the condition of affairs; this done, replace them at once for fear of chilling the brood. By so doing, the queen-bees will hardly be conscious of any disturbance at all. When combs are treated in this way, it is quite a common thing to see the queen carrying on her important work of egg-laying without any interruption at all during the handling, and she may be watched going from cell to cell depositing an egg in all the empty ones. The queen usually lays four or five eggs in rapid succession, and then rests a minute or two to be fed and stroked over or rubbed down (for this egg-laying business is an arduous task) by the adjacent bees, and the operation again repeated. In early spring, however, eggs are not laid nearly so rapidly as later on; the queen has not yet got into full working order. Be watchful now for old or worn-out queens, such are better destroyed without delay, and the bees united to a stock with a good queen. Then run for all they are worth such, strengthened stocks up to the end of harvest-time, and then divide into two again in the usual manner. On examining a cell just after an egg is laid, a small pearly speck is seen standing on end at the bottom, but slightly on one side of the cell-base. A semi-liquid substance covers the egg and attaches it in position, this is speedily laid down at the bottom of the cell by one of the nurse-bees, and in the course of the next two days is turned over by them so as to respectively assume the angles of 35 and 50 deg. before it hatches, which takes place early on the fourth day after it has been laid. Nearly all eggs laid thus early in the year will produce worker-bees; the time has not yet come for the drone, though towards the end of the month these gentry will be found on the way in all flourishing colonies, especially when the queen is over two years old. Many old-fashioned bee-keepers welcome the early drone, but although often a sign of prosperity, it is occasionally a sign of near exhaustion of the laying powers of the queen. This is a point not to be lost sight of, and to be guarded against, for a queen that is found producing an abnormal quantity of drones at this season is not worth keeping, if any regard is had for the ultimate harvest of honey.

Mead.—For making mead from honey-comb, I send a description of the way we make ours, viz.: Cut the comb up in small pieces about the size of a Walnut. Place in a clean washing-pan, cover with warm-water, no hotter than you can bear your hand in comfortably. Let it soak half-an-hour, add a little warm-water, and then squeeze the comb up with your hand. It will break all to pieces. Next tie a cheese-cloth over another pan, and pour the contents of the first pan on the cloth. When the liquid portion has run through, pour it back again into the empty pan, and add more warm-water, and squeeze the whole again well. Next add as much water as will make up the quantity of mead required. Strain again through the cloth, and when all has drained through the cloth, squeeze the latter to get the whole out, and pour into a clean boiler. It does not matter whether it is a galvanised boiler or not, just for the boiling, but the liquor must not stand in a galvanised-vessel for any length of time. While in the boiler, drop a fresh egg in, and if the egg shows itself nearly half its size above the top of the liquor, you will have some real strong mead by the time it has been kept about twelve months. If the egg goes to the bottom your liquor will be small beer. In the latter case, to make it the desired strength, more honey or sugar must be added till the egg will rise to the proper height. It is, however, no use adding honey or sugar unless you have the liquor warm enough to melt it. When made right let it boil half-an-hour steadily; while boiling put ½ lb. hard ginger tied up in thin rag, also ¼ lb. cloves, to each nine gallons. When taken from the fire put it outside to cool, but before quite cold toast a bit of bread, and put a small quantity of yeast on it to start it fermenting. Next day put it in your barrel, but do not cork it up tight for some time, and put the ginger and cloves in the barrel with the mead. This is how we have made our mead for the last forty years, and I do not remember ever having any spoiled. We have made it in iron-boilers and in galvanised ones, but never found any difference; there is no fear if it is done right.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, APRIL 9—Royal Botanic Society, meeting.
TUESDAY, APRIL 12—Royal Horticultural Society's Committees.
SATURDAY, APRIL 16—Ghent Quinquennial Horticultural Exhibition, open until 24th inst.

SALES.

WEDNESDAY, APRIL 13—Japanese Lilies, 1600 Roses, Herbaceous Plants, Gladioli, &c., at Protheroe & Morris' Rooms.
THURSDAY, APRIL 14—Border Plants, Lilliums, Bulbs, Palms, Roses, &c., at Mr. Stevens' Rooms.
FRIDAY, APRIL 15—Stove and Greenhouse Ferns, Japanese Iris, Begonias, Cannas, &c., at Protheroe & Morris' Rooms.
Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—47° 6'.

ACTUAL TEMPERATURES:—

LONDON.—April 5 (6 P.M.): Max., 51°; Min., 36°.

PROVINCES.—April 5 (6 P.M.): Max., 51°, Valentia Point; Min., 36°, Shetland.

Fair, rainy; frost at night.

Ghent Quinquennial Exhibition. IT is expected that the floral display at this exhibition, and the collections of plants remarkable for their cultivation, will exceed any hitherto seen on these occasions. Cape plants will be largely shown. Probably a collection of plants shown by the late JOHN LINDEN will also be exhibited. The different sections for nurserymen and amateurs will be judged by jurors unconnected with the city of Ghent, hence the position of a member of the jury of the exhibition will in itself be a distinction much appreciated in the horticultural world. The following list, taken from the *Semaine Horticole*, shows how varied are the nationalities of those who have accepted the invitation of the organising committee. So far, the jury is composed of 211 horticulturists of note, including 25 Germans, 30 English, 54 Belgians, 16 Dutchmen, 6 Italians, 4 Russians, 2 Swedes, 4 Swiss, 67 Frenchmen, 3 from Luxemburg, and delegates from Austria, Brazil, Spain, and even from Japan. The exhibition, which will remain open until Sunday, April 24, will be visited by H. M. King LEOPOLD at 8 A.M. on Saturday, April 16, for the purpose of viewing the exhibition, and meeting the members of the jury. His Majesty will also officially pronounce the opening of the exhibition at 10 A.M. on that day. We are also informed that it is probable that His Majesty will on Sunday, April 17, give a garden-party at Läckén, to which the diplomatic body and the members of the jury will be invited. The Veitch medals awarded to M. le Comte de KERCHOVE, the President of the Ghent Society, to M. ED. ANDRÉ, the Editor of the *Revue Horticole*, and to M. LATOUR-MARLIAC, the raiser of the beautiful hybrid Nymphaeas, will, it is expected, be presented at the luncheon to the jury on the 15th. On Saturday, the 16th an "International Raout" will be held at 8 P.M., at the Société Union; evening dress. On Sunday, a concert will be held in the Place d'Armes, at noon. The Banquet to the Jury

will be held on the 17th inst., in the Salon of the Great Theatre. It will be attended by some of the Ministers and other notabilities.

Free admission will be accorded to all the horticultural establishments, the Botanic Garden, Hotel de Ville, Belfry, Ruins of St. Bavon, and Museums of the city. Various Clubs, such as the "Union," the "Concorde," the "Société Royale des Mélomanes," will be accessible to the jurors.

Amateur Gardeners.

THE editor of the new issue of *Who's Who* invited a large number of celebrated people to confide to him details of their favourite recreations. Several thousands of them responded, and the total number of entries thus obtained, counting separately the various recreations given by each, is about 6000. Of these, 219 people professed an interest in their leisure moments in gardening, farming, forestry, and fruit-raising, while 30 more declared themselves to be plant-collectors. An analysis of the ordinary vocations of the men and women who find in the garden the best change of occupation will not be without its interest:—

Littérateurs	42	Civil Servants	7
Professors and school-masters	27	Actors	5
Artists	15	Soldiers	4
Lawyers	14	Landowners	4
Clergy	13	Doctors	3
Titled persons	11	Politicians	3
		Miscellaneous	7

Amongst authors one may particularise Miss Braddon and Mrs. Mona Caird, Mr. Manville Fenn and Mr. Rider Haggard, Mr. W. C. Hazlitt and Mrs. Lynn Linton, Mrs. Macquoid and Miss Helen Mathers, Mr. J. E. Muddock and Mrs. Beedell, Lady Verney and Mrs. Woods, Mrs. Amelia Barr and Mr. Harold Frederic, Mr. George Kennan and Miss Flo. Marryat, Lady Dorothy Nevill and Miss Beatrice Harraden, Mr. Thomas Hardy and Mr. G. W. Cable.

The professional element is also strong. It includes physiologists like Professor Michael Foster and Dr. Lionel Beale; physicians like Dr. Yeo and Dr. G. V. Poore, Sir William Gowers and Sir W. O. Priestley; librarians like Sir E. Maunde Thompson; botanists like Dr. Marshall Ward, Professor Oliver, and Mr. Pickering; zoologists like Professor Poulton and Miss E. Ormerod; schoolmasters like the Rev. W. G. Rutherford of Westminster and Mr. Bosworth Smith of Harrow; geologists like Professor Boyd Dawkins; chemists like Mr. W. H. Perkin and Dr. Liveing, mathematicians like Professor Allman and Mr. J. J. Walker, Biblical scholars like Dr. C. H. Wright, art critics like Sir John Robinson, educationists like Sir Philip Magnus, and archaeologists like Sir Herbert Maxwell. Amongst the artists are Mr. Francis Bate and Mr. Stanhope Forbes, Mr. G. D. Leslie and Mrs. Ernest Normand, Mr. Alfred Parsons and Mr. Hamo Thornycroft, Mr. Louis Wain and Mr. J. C. Hook, Mr. T. G. Jackson and Mr. Colcutt; the architects are also in the list.

The lawyers may be represented by names so various as Mr. Justice Wills and Mr. Horace Smith, the Solicitor to the Grenadier Guards, and the Chief Justice of Tasmania, Lord Kincairney and Mr. Maclaren, Mr. Alderman Rogers and Mr. Parker Reed, Q.C.

Nor should mention be omitted of the Governor-General of Canada and Lord Battersea, Lord Armstrong and Sir John Edwards-Moss, the Countess of Warwick and Sir Henry Bellingham; while amongst those who take an interest in forest-culture are Lord Bangor, the Earls of Southesk and Courtown, and Lord Charlemont, Lord Middleton, and Sir James Whitehead. It goes without saying that amateur gardeners

are very largely represented amongst the clergy; from Dean Hole to Dr. Jessopp, Canon Isaac Taylor to the Bishop of Worcester, Canon Eyton to the Rev. Thomas Hincks, the Sub-Dean of Manchester and Archdeacon Barber, Canon Bernard and the Prebendary of Wells, the Bishops of Thetford and Southwark, and the Rev. James Rankin. In another calling one should not omit the Secretary of the Education Department, Sir Ernest Satow, Sir Thomas Lister, the late Sir James Stansfeld, and Sir Richard Temple. The actors include Mr. George Giddens and Mr. Edward Terry, Mr. Lionel Brough, Miss Marion Terry, and Mr. Henry Neville; the soldiers, Sir Henry Colville and Lieut.-Colonel Ross of Bladensburg, Colonel Waring and Sir Brook Kay; the doctors, Sir George Birdwood, Mrs. Elizabeth Anderson, and Dr. Fleming, until recently the principal veterinary-surgeon to the Army.

Besides all these who find a delight in the practice of horticulture, there are others who seek relaxation in the pursuit of botanical study. These are men of affairs like Lord Battersea and Sir M. Grant-Duff, Sir Herbert Maxwell and the Secretary of the London Institution; scientists, like Prof. E. B. Cowell and P. A. Simpson; authors like Miss d'Esterre Keeling, and Miss Yonge; with Mr. Latimer Clark the engineer, Miss Olga Nethersole the actress, and Sir William Huggins the astronomer.

These examples will suffice to show that the oldest of all human avocations still holds men, however much the division of labour now-a-days may have carried them in their ordinary work away from the tillage of the soil.

LINNEAN SOCIETY.—The next meeting of the society will be held on Thursday, April 7, at 8 P.M. precisely, when the following papers will be read:—Dr. ELLIOTT SMITH, "On the Brain of the Edentata, including Chlamyphorus." (Communicated by Prof. HOWES, Sec.L.S.) Mr. H. FARQUHAR, "Preliminary Account of some New Zealand Actinaria." (Communicated by T. W. KIRK, F.L.S.) Exhibitions:—Mr. J. E. HARTING. (1) A specimen of the Asiatic Partridge, *Perdix daurica*, of which a large consignment has been lately received in London via St. Petersburg. (2) A skin and skull of the Wild Cat (*Felis catus*), recently obtained in Inverness shire.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, April 12, in the Drill Hall, James Street, Westminster, from 1 to 5 P.M. A lecture on "Blight and Blessing," illustrated by lantern slides, will be given by Mr. FRED ENOCK, F.L.S., at 3 o'clock.

CAPE FRUIT.—The *Scot* has arrived with 570 boxes of Grapes and Pears—of the latter, 22 is the number. Of the Grapes it is said "some of them turned out in excellent condition, and realised top prices, while others were very wet, and hardly worth selling. The few boxes of Pears were in first-class condition.

CUCUMBER "EVERYDAY."—We learn that this new Cucumber, raised by Mr. OWEN THOMAS, of the Royal Gardens, Windsor, and exhibited by him at the Royal Horticultural Society's meeting on December 14, February 4 (when it was recommended an Award of Merit), and on March 4, when it was awarded a First-class Certificate, will be distributed next year by Messrs. SUTTON & SONS, of Reading.

TASMANIAN FRUIT.—The P. and O. Steamship Company inform us that the ss. *Ormuz*, with 16,000 boxes, and the ss. *India*, with 18,000 boxes of Apples, are now en route. The *India* is expected about the 7th proximo. No date is given for the probable arrival of the *Ormuz*.

FIG. 81.—THE DOWNES HAYLE, THE RESIDENCE OF THE REV. T. JAMES. (SEE P. 219.)

Photo by R. H. Preston, P.

GARDENERS' ROYAL BENEVOLENT INSTITUTION VICTORIAN ERA FUND.—Your readers will doubtless remember that this Fund was established last year to commemorate the completion of the sixtieth year of Her Majesty's beneficent reign. They will also recollect that its object is to temporarily assist unsuccessful candidates whilst awaiting election who have been (or their husbands) subscribers to, or life members of, the Institution. The total amount received for this fund up to Dec. 31 last has been invested, and the committee are glad to be able to announce that the income derivable therefrom this year enables them to distribute the sum of £106 10s., the first half of which was sent on April 1 last to eighteen unsuccessful candidates as follows, and has been divided at the rate of 15s. for each year they (or their husbands) had subscribed:—

	Years self or husband subscribed.	Amount sent April 1, 1898.
Bryan, Andrew ...	13	£4 17 6
Nixon, Francis ...	13	4 17 6
Plevy, James ...	12	4 10 0
Staples, George ...	11	4 2 6
Wood, Caroline ...	11	4 2 6
Gibbons, John ...	10	3 15 0
Watt, James ...	10	3 15 0
Hackwell, Elizabeth ...	9	3 7 6
Wills, George ...	9	3 7 6
Barnfield, Alfred ...	8	3 0 0
Hatch, Annie ...	8	3 0 0
Mitchell, Lucy ...	7	2 12 6
Shearn, Joseph ...	7	2 12 6
Lee, Alexander ...	5	1 17 6
Evans, Thomas ...	4	1 10 0
Gould, William ...	2	0 15 0
Thomas, William ...	2	0 15 0
Woodward, Emma ...	1	0 7 6

From the above it will be seen that the aggregate number of years of subscriptions is 142, which at 15s. for each year gives a total of £106 10s., the first instalment of which, as already stated, was sent on April 1 last, and the remainder will be sent on October 1 next. The Committee are very anxious to bring up the total amount of this Fund to £5000, to do which they require a sum of £925, and I should like to draw attention to the generous offer made by N. N. SHERWOOD, Esq., Trustee, to contribute £50 provided the amount required be raised, in response to which the following gentlemen have each kindly promised a similar sum:—

ARTHUR W. SUTTON, Esq., Reading.

LEONARD SUTTON, Esq., Reading.

HARRY J. VEITCH, Esq., Treasurer.

and several smaller contributions have been already received. The Committee sincerely hope before the close of the year they may be able to announce that the balance to make up this £5000 has been received. They trust, therefore, that every well-wisher of the Institution will note that the "Victorian Era Fund" is still open, and that donations to it will be most gratefully received. The committee also desire again to emphasise the notice which has already appeared in your columns and elsewhere, that the benefits of this particular Fund are intended for those only who have been subscribers to the Institution. GEORGE J. INGRAM, Secretary.

THE NATIONAL CHRYSANTHEMUM SOCIETY.—The recent smoking concert held in connection with the National Chrysanthemum Society, resulted in a net balance of £8 9s. 5d., which has been contributed to the funds of the Society. The Hon. Stewards Committee, through whose efforts the function was promoted, desire to express their thanks to the many friends who assisted in making the Concert a success.

THE SAN JOSÉ SCALE.—We learn that Prof. J. RITZEMA Bos, Director of the Phytopathological Laboratory, "Willie Commelin Scholten," at Amsterdam, will shortly be despatched to America by the Dutch Government to study the San José Scale. The Dutch law does not prevent, as Germany has done, the introduction of fresh fruit from America, but it is of great importance to European countries to know if really this scale will thrive here, and we congratulate the Dutch Government on their foresight and enterprise.

INFLUENCE OF THE X-RAYS ON THE VEGETATION OF SEEDS.—MM. MALDINEY and THOUVENIN communicated to a recent issue of the *Comptes Rendus* the result of their experiments with certain seeds grown under the influence of the X-rays. The plants selected for experiment were *Convolvulus arvensis*, *Lepidium sativum*, and *Panicum miliaceum*; three seeds of each were submitted to the action of the rays, and a corresponding number grown under exactly the same conditions, but without being so exposed. In the result the seeds sown under normal conditions were behind the others in germinating. "It may perhaps be objected," says the experimenter, "that the X-rays produce an elevation of temperature in the ground submitted to their action, and that therefore it is quite natural that seeds sown in such soil should germinate before others not so treated. But such is not the case. The experiments were made by the aid of a pair of thermo-electric needles attached to a very sensitive Thomson galvanometer, and no appreciable difference in temperature could be ascertained between ground subjected for two hours to the X-rays and that which was not so exposed. We may therefore conclude that the rays hasten germination, at least of the seeds of *Convolvulus arvensis*, *Lepidium sativum*, and *Panicum miliaceum*. Further, as the young plants, on issuing from the seed, are habitually of a pale yellow colour, we may deduce the fact that the X-rays appear to be without influence to hasten the formation of chlorophyll in germinating plants."

ORCHARDS AND VINEYARDS AT THE CAPE.—For many there is always a charm in figures, especially when they have relation to horticulture. The pictures they often succeed in conjuring up are always beautiful, mentally; and in the matter of fruit-trees with the knowledge of surface necessary for their proper cultivation, the gross acreage of land devoted to fruit is readily set out. In the just-published "Agricultural and Live-Stock Returns for 1896-97, issued in connection with the Statistical Register of the Colony of the Cape of Good Hope," we find quite an army of figures, a few of which are selected for publication in these columns, and these relate to the fruits grown at the Cape, including the Vine to the whole colony, including Pondoland, but excluding Bechuanaland. We have space only for the "grand total" of all the divisions reported upon, and this in most cases by the police of the several districts and other officials. The array selected relates to "fruit trees planted" and "fruit trees standing":—

Name of Fruit.	No. Planted.	No. Standing.
Peach ...	102,303	1,638,560
Apricot ...	32,344	287,197
Apple ...	43,970	407,674
Pear ...	28,338	316,272
Plum ...	30,766	176,254
Fig ...	45,325	1,019,512
Orange... ..	29,980	215,016
Lemon... ..	2,850	30,510
Naartje ...	3,562	22,876

The figures relating to the Vine industry are few, and are as follows:—Vine stocks planted, 5,867,760; ditto destroyed, 6,817,303; ditto standing, 36,533,019. Certainly the total of the existing vineyards is a great one; the product ought to make a good show. Of raisins the product was 2,019,561 lb.; the wine supplied was 34,435 leaguers. This measure represents 128 gallons, so that the product was exactly 4,407,680 gallons. Brandy was produced to the extent of 1,410,624 gallons. It may be noted that the first horticultural census was made so recently as 1891, the first publication of the figures by the Agricultural Department dating 1893; and these, we trust, justifying the space occupied by them here.

PUBLICATIONS RECEIVED.—The *Agricultural Gazette of New South Wales*, January, 1898, includes papers on Wine-making, Fermentation; *Panicum*

pygmæum; Stringy Barks of New South Wales; Fruit-tree and Vine Pests; Comboyne Brush; Export of Oranges, &c.—*Tijdschrift over Plantenziekten* (Ghent), 1897.—*English Illustrated Magazine*, April, 1898.

THE DOWNES, HAYLE.

THIS garden was laid out in 1867 by the late Mr. Rawlings under the direction of John Sedding, the architect. As the ground was practically a *tabula rasa*, everything remained to be done, and every step was taken deliberately, and in furtherance of a preconceived scheme. Money was not spared, and the grounds contain no shoddy work.

The house itself is a beautiful one, semi-Gothic in general character, now well overgrown with evergreen and other creepers. It stands on the summit of a slope, at whose base is the town of Hayle and the sea-level. As an example of architect's gardening, The Downes may be considered a very favourable specimen, though, as the house has been long unoccupied, and the garden consequently neglected, it is a little difficult to discount the toning-down of formality which nature has meanwhile effected. One is spared the more dreadful puerilities of which Mr. Sedding has elsewhere expressed himself as capable: "In the formal part of my garden, my Yews should take the shape of pyramids, or peacocks, or cocked hats, or rampant lions in Lincoln green, or any other conceit I had a mind to."

Still, the architect's influence in the garden, even when the formalising is moderated as at The Downes, is seen to be essentially evil. The compasses and rulers of the office have little function in the garden. Mr. Rawlings took great pride in the considerable collection of choice Hollies he got together at much trouble and cost, but he caused nearly every one to be clipped as one clips a Privet-hedge, so that the leaves alone remain of the beauty and character of the trees. A double avenue of pyramidally-clipped Yews show up the natural beauty of a graceful Cedar hard by, which has escaped the topiarist.

The tiled edging of the beds is all that remains of a geometrical garden, which must in its glory have rivalled a child's sampler in artistic significance. In this department, Mr. Rawlings endeavoured to carry out the ideas and colour schemes formulated in Sir Gardiner Wilkinson's book "On Colour and Taste;" and all the patterns were annually submitted to Mr. Sedding for approval, the colours being actually laid in pigments in the beds before planting. Needless to say, the architect caused the garden, although but slightly inclined, to be laid out in a series of half-a-dozen terraces, each but a few feet below its neighbour.

Still, the formality of the garden is by no means its only feature, and even its formality will appeal to many. Once we get off the line of the formal steps and main walks, we come across beautiful little pieces of garden where herbaceous plants grow in pleasant natural groups, and all is retired and reposeful. A stretch of lawn extends on the western side of the house; and on the second terrace, within a row of clipped Yew, is a piece of grass, formerly a bowling-green. The clipped edges are mostly well-grown and kept, on the north of the upper terrace being a splendid Sweet Bay-hedge many feet in thickness.

On the east of the house, where is the main entrance, is a pleasant court-yard bounded by Ivy-covered walls, which is approached from the road by a short avenue of deciduous trees.

On the whole, then, we may say that, from the point of view of those who hold the opinion that a garden should be obviously a piece of architecture, The Downes is nearly perfect; whilst, even to those who feel that a great part of the art of gardening is the concealment of artifice, the place will appeal as a fine example of formal gardening, which has been pursued without altogether forgetting the beauty of hardy plants naturally grouped, and of unbroken greensward. It is now the residence of the Rev. T. James. The photograph was taken by R. H. Preston, of Penzance. *Harry Roberts.*

HOME CORRESPONDENCE.

CAROLINE TESTOUT, AND OTHER HYBRID TEAS.—I am much obliged to Mr. C. Bennet of Surbiton for his interesting and appreciative observations regarding my recent article in the *Gardeners' Chronicle*. I have often been somewhat sceptical myself regarding the generally-accepted derivation of Caroline Testout, and have frequently drawn the attention of intelligent visitors to my garden to the differences existing between this variety and La France, especially the perfume and the shape of the flowers. Caroline Testout here is of much stronger growth than its pink predecessor, and produces a much larger number of blooms, which, however, have not an equal number of central petals. My friend, Mr. Wilson, Minister of the Trossachs, beside Loch Katrine, who is a highly successful cultivator of Roses, writes me to say that Caroline Testout is the grandest and most reliable Rose in his garden. I can say almost as much regarding its merits, notwithstanding its lack of central compactness, when compared with La France. I have long been of opinion that the fragrance of the two Roses to which I have been referring is by no means the same; and if such is the case, the opinion of Mr. Bennet that Caroline Testout must have had another parent of a somewhat different character, and capable of hip-production, is thereby emphasised. Mrs. W. J. Grant was the result of cross-fertilisation between La France and Lady Mary Fitzwilliam. It is very attractive in bud-form, but not so impressive at any subsequent stage. *David R. Williamson.*

THEN AND NOW.—The writer of the note under above heading seems to have misunderstood the arrangement of Evelyn's *Kalendarium Hortense*. The two pages devoted to each month are divided into four sections. "To be done in the Parterre, &c.," being the third, and "Flowers in Prime or yet Lasting," the fourth. The two are necessarily quite distinct, the one from the other, the last containing the names of plants, whether trees, shrubs, or hardy or tender flowers in bloom; the other, work necessary to be performed in the garden, &c. The tender plants named Oriental Jacynth (*Hyacinths*), Levantine Narcissus (*Polyanthus Narcissus*), and *Præcox*, or early Tulips, required to be forwarded by means of a hot-bed, which till some time after 1664 was of a primitive character. It was constructed in the following manner. A spot was chosen, and the ground marked off to the size required. A hole was then dug out to a depth of 4 feet, and this was filled with heating material, about which there was some disagreement as to what was the best for the purpose. The covering was of mats supported on bent sticks, and the introduction of boxes instead of mats was considered a very progressive step. By means of these rude hotbeds, many tender plants were raised from seeds, and, as in the case under notice, plants forced into bloom. These plants, when in flower, appear to have been employed for decorating apartments in the dwelling-house. The greenhouse was merely a place for protecting plants during the winter season. Evelyn's is mentioned as being "a pretty little greenhouse, with an indifferent stock in it," also "his garden, not being walled, has little of the best fruits." Like "Sylva," "P. mona," &c., Evelyn takes credit only for presenting, in a readily accessible form these and this calendar of operations, which he is honest enough to declare was not the unaided labour of his own hands, but the work of the best gardeners he was acquainted with. On account of the pedantic employment of what were then "scientific" names, "Flowers in Prime" provides the most difficult reading that a gardener has to tackle; nor does the writer always employ the same designation as others; Levantine Narcissus, for instance, being commonly called Narcissus of Constantinople. *R. P. B.*

PINE-APPLE CULTURE.—"An Italian doctor has discovered that there is in the common Pine-apple a substance similar to pepsine, which has the most astonishing qualities. At all events, he declares that the juice of a single Pine-apple will digest 10 lb. of beef! And he has further found that its juice is a very active solvent of the growth or membrane formed in diphtheria. If all this be true, as I hear it is, Pine-apples will be dearer than ever; but we shall not begrudge our guineas for such pleasant remedies for dyspepsia and diphtheria, certainly." When reading the above extract in a recent issue of the *Leeds Mercury Weekly Supplement*, as an old Pine-grower one, seemed to see visions of acres of glass being

erected to grow Pine-apples to meet the public demand. Then came the more sober thought, "Oh! it is only a sort of gardening sea-serpent story." No doubt, if what is there mentioned had any foundation in fact, we should have had the subject "chronicled" before this. However, as history is said to repeat itself in certain cycles, perhaps some of your readers may live to see Pine-growing for market again an accomplished fact. Who would have thought it possible, say, twenty years ago, that the huge demand for Grapes and Tomatos would have been what it now is. Of course, I am well aware that Pines are much more expensive to produce than either Tomatos or Grapes. Still, should there grow up a large public demand for English-grown Pines, no doubt it could and would be met at a much less cost than was the case, say, thirty years since. In mentioning the matter, I do not infer it will be so, but thought I would forward you the above clipping. *H. J. C. Grimston, Tadcaster.*

MAGNOLIA STELLATA.—We find this species of Magnolia to be a useful plant for forcing into flower in the winter, the flowers appearing very freely from the tips of the previous year's growth. One of our plants produced nearly forty of its very characteristic white stellate flowers during the early part of March. This plant is growing in an 8-inch pot in a mixture of equal parts of fibrous loam and peat. The species is quite hardy, but plants that have been forced should not be turned out-of-doors before they have undergone a process of hardening off; the same kind of treatment as that afforded Azalea mollis suits it very well. Seeing that its flowers are produced before the foliage, it is scarcely adapted for the decoration of apartments; but for mixing with other flowers, making up wreaths, or other forms of floral decorations, I find it a very useful flower. I am surprised that the plant has not found favour with enterprising nurserymen, and offered in the autumn along with Lilacs, Azalea mollis, and others used for winter forcing. Perhaps there may be some difficulty in propagating it in quantity? *H. J. C.*

HIPPEASTRUMS.—It was stated in last week's *Gardeners' Chronicle* that a yellow or white self Amaryllis has still to be looked for. We beg to say that our variety, Aphrodite, has been in commerce for a good many years now, and is pure white in the petal, with no admixture of red in any shade; it is also of good shape. We notice at last two seedlings have flowered as white selfs this year with us, so that this new ground is now apparently broken up. *Kelway & Son.*

MORE ABOUT WATER-BOUQUETS.—These used to be common at flower-shows, and they were occasionally used for public and private decorations. The fashion, however, did not last very long. It was difficult to fix the bouquet in the right place, to choose material, to place the bell-glass over the bouquet, to fill with water, and to remove the bouquet from the water to the dry stand. Taking the last first, I had a rather serious accident some years since with a huge water-bouquet at a provincial show. This bell-glass was some 2 feet in diameter, and over 2 feet high. Neither a pail nor a tub could be found, nor water sufficiently clear near the show-tent to flood, or rather suspend, the bouquet in water; hence my resort, single-handed, to a lake in the park some distance off. It was difficult to find a solid standing-place. But the water was clear and deep; and after considerable difficulty in floating and submerging the bouquet, which looked lovely in the water, the huge bell-glass or globe was placed over, and every bubble of air drowned out, and a china-plate slipped under it before the crown of the bouquet reached the surface of the water. No sooner, however, did I attempt to lift the complete water-bouquet out of the water than it strove to drag me into the lake, and this weight of the flowers, the water, china-plate, and bell-glass, and the pressure of the atmosphere on the glass-globe were so great that they nearly succeeded. After a sharp short struggle the glass gave way, the plate sank to the bottom of the lake, and the bouquet which had been weighted with lead to preserve its position, gracefully disappeared. It need hardly be added that this was the last of my monster water-bouquets made for exhibitions. Water-bouquets of medium or small size are the most beautiful as a rule. One of the chief points is this filling of the glass quite full of water, another is the choice of globes with a level bottom as well as a base, dish or plate with a smooth or even base. The object of this is to enable the glass and the plate to form an impenetrable barrier between the water and the air. Hence the glass, whether large or small, pressed down by the weight of the air clings to

the base of the water-bouquet as the limpet to the rock, or the sucker of wet leather to the stone. Then no attempt must be made to remove the glass, or repair water-bouquets without first plunging them overhead in a pail or tub of water. As to steadying the bouquet in the water, it is a great mistake to use a lump of clay, as suggested by one of your correspondents, as this would soil the water, and prevent the flowers and leaves from being clearly seen. There is nothing to equal a bullet of lead, worked into the centre of the stem. The whole of the materials of water-bouquets must also be scrupulously clean. The bouquets should likewise be an artistic bunch of Ferns, flower-leaves, grasses, rather than a formal hand-dress or drooping bouquets of the usual forms. This change of front and form in water-bouquets gets rid of most of the difficulties of hiding unsightly stems or stalks. No mistake did more to lower or ruin the popularity of water-bouquets than overcrowding. Not a few seen by the writer conveyed the impression that the chief purpose of their makers was the crowding of as many leaves and flowers into their novel position as could be managed, no matter with what amount of crushing against the glass. Whereas the primary object of every water-bouquet should be to display, in the most artistic manner, every leaf and flower used, and preserve their freshness and beauty as long as possible, and magnify both through their limpid setting. This making and placing of water bouquets needs cultured taste. The setting, like the last touches of the artist on his canvas, not seldom makes or ruins the effect. In both cases, courage, firm handling, and skilful manipulation are needful at the finish. The water bouquet must have its last touches under water, and the artists who fear to take off their coats and tuck up their shirt-sleeves, will seldom succeed perfectly. A few touches of the leaves and flowers before the glass barrier separates us from them makes all the difference, often between the highest art and the common-place. *D. T. F.*

ALSTROEMERIAS.—I have read Mr. Ward's explanation concerning these plants, yet I cannot at all agree with the following piece of advice tendered by him. Mr. Ward says, "Even for early autumn planting, plants established in pots are preferable." It is the exact opposite in my opinion, and there is in truth no more occasion for purchasing such things as Alstroemerias in pots from the end of August to the end of January ensuing than there is to purchase Crocuses, Hyacinths, or Tulips in pots for a similar purpose. Mr. Ward does not appear to be aware that dozens of continental bulb-farmers, and also English growers of miscellaneous bulbous and tuberous-rooted plants have special methods in producing the right sort of saleable root, a matter only to be accomplished by, among other things, an annual lifting, a sorting, and a replanting of the group in question. In this way it is made possible for the flower-farmer to obtain from the wholesale bulb dealers 100, or even 200, by parcel-post (all prime flowering roots), for a few pence. Whereas purchasing such things in pots would mean a cost of several shillings incurred in carriage, apart from the cost of packing, &c. Therefore I must challenge Mr. Ward's recommendation from two standpoints, viz., the practical and the economical, the latter invariably a carefully guarded item by the flower-farmer. I note also that Mr. Ward recommends raising stock by means of seeds, which in some respects I agree with; yet, while giving "18 inches" between rows, and "1 foot apart" for the "patches of three or four seeds," which on his own showing require fifteen months to attain to flowering size, the same writer would cramp an already developed plant into a pot. Surely if the seeds of these Alstroemerias require so much freedom as 18 inches by 12 inches asunder in the rows, &c., a plant already past the seedling stage cannot be benefited by being confined in the small pots usually adopted by the trade. Nor is this potting usually done or intended for wholesale purchasers of such things, but rather for amateurs and others who purchase these things at varying seasons or at flowering time. The pot system is one of the necessary evils of the trade, as I know full well. Mr. Ward quotes two sources to support certain of his views, yet the very guarded reply attributed to Mr. Ward, viz., that "some are grown in large quantities," does not in the least support Mr. Ward's original statement, wherein all the reputedly hardy kinds were unconditionally recommended for field culture. So far as the hardness of these plants is concerned, my experience coincides with that of Mr. Divers, that at 6 inches deep the majority of the species are safe. At 3 or 4 inches deep I have known many hundreds to be killed outright by

frost. At 6 or 8 inches deep, the latter always preferred by myself in this district, I have grown many thousands of the best known kinds without the loss of any of them. Of this quantity a goodly proportion was reserved for annual lifting to supply customers, and only those directly engaged in the work can form any idea of the superior character of the roots which this system and good tillage furnish. *E. Jenkins, Hampton Hill.*

LONICERA FRAGRANTISSIMA.—On the south side of the house I live in there is a large plant of this winter and early spring flowering Honeysuckle, which for the past four months has not been without flowers. It is a sub-evergreen variety, that is, during mild winters, such as the present one has been (it has been snowing all day here), it does not lose its foliage. In good soils it is a rampant grower, and is especially suitable for mixing with other rapid-growing climbers for covering high walls facing south or west. The warmer the previous summer, and therefore the better ripened the wood, so will be the freedom of its flowering the following winter and spring. As will be known to many, its flowers are not of a showy nature. During the sunny days that always occur more or less each winter, their fragrance can be recognised at some distance away from the plant. It is increased by cuttings inserted in a cold frame in October or November. Small side shoots of the previous year's growth taken off with a heel will root fairly well. Though by no means a showy plant as to its flowers, it well deserves a place in any collection of hardy plants requiring a warm wall for their successful growth. *H. J. C., March 25.*

APPLE NEWTON WONDER.—This variety was raised by Mr. W. Taylor, at King's Newton, and is a cross between Blenheim Orange and Normanton Wonder, and both varieties can easily be traced in it. I have this morning seen the mother-tree, and it certainly is a grand specimen. The trunk is about 30 inches round, and the tree is literally covered with flower-buds. As to its cropping habit, I have seen small trees, about 3 feet high, with as many as thirty-six Apples on, and the fruits will keep till September the following year. The fruit-tree grafted from this mother-tree is now growing at Stanton-by-Bridge, and looks quite as well as its mother. Mr. Taylor has sent grafts to New Zealand, and also to America, where it is likely to be grown very largely, as it is a heavy, solid, and good-keeping variety. I saw Mr. Taylor weigh last week sixteen Apples, and they were 9 lb. good weight. It is a sterling Apple. *Thos. Salsbury, Market Gardener, King's Newton.*

WHAT IS COCOS WEDDELLIANA, HORT.?—Drude, in his monograph of Palms in the *Flora Brasiliensis*, says that this is the same as *Glaziova Martiana*, Glaziou, of which also *Glaziova elegantissima*, hort., is a synonym. I must confess that a closer examination of the *Cocos Weddelliana*, hort., shows such great differences from *Glaziova Martiana*, Glaziou, that it hardly can be united with it. Drude describes *Glaziova Martiana* as having segments, "e basi paulum reflexa angustissime lineari-lanceolata in acumen integrum elongata, in facie inferiore glaucescentia, media 12 cm. longa et 4 mm. lata, ad apicem sensim decrescentia, in plantis læte vigentibus autem multo longiora sed semper angusta." The leaf of this plant, of which Drude gives an illustration on tab. 86, shows very little resemblance to the leaves of *Cocos Weddelliana*, hort. The segments are elongate acuminate, very sharply pointed, and the apex is, as the description says, "integer." The *Cocos Weddelliana*, hort., in all those specimens which I have seen, has segments of which one half is half-an-inch and more longer than the other one. Besides this character, the fruits and seeds show differences of some importance, so that, till I have seen flowers of *Cocos Weddelliana*, hort., I must take it for a distinct species. But how to name it? There is already a *Cocos Weddelliana*, Drude (*Hort. Bras.*, p. 411, tab. 90), which is quite another plant. This was published in 1882, whilst *Cocos Weddelliana*, hort., was before mentioned by H. Wendland, without description in Comte Kerchove de Denterghem's *Les Palmiers*. It is true this is a *nomen nudum*, but, notwithstanding, if our plant should prove to be a true *Cocos* I should not hesitate to give it the name *Cocos Weddelliana*, Wendland, which is well known to every one. I think it is nonsense to give to a plant well known to everyone for twenty years or more another name, only because there exists no description, whilst another species, known only to some botanists by dried specimens, was baptised with the same name and equipped with a description. *Dr. Dummer.*

COCOS WEDDELLIANA.—H. Wendl. is not a *nomen nudum*, although no description is given in Kerchove's *Les Palmiers*, published in 1878, because a full diagnosis by Wendland is appended, as a footnote, to an article (with figure) on the species by T. Moore in the *Florist and Pomologist*, 1871, p. 114. In the latest monograph of *Cocos* by Beccari, the species is held to be good (see *Malpighia*, i., 1887, p. 443). Beccari agrees in synonymy with Drude. Van Houtte in *Fl. Serres* [1873], t. 2000, says "Introduite par nous, du Brésil, il y a une quinzaine d'années, elle trouve toujours preneurs et reste comparativement rare." The localities given by Beccari are:—Prov. of Rio Janeiro: Serra dos Orgãos, and Serra d'Estrella, alt. 800 mètres. The following is the synonymy given by Beccari:

COCOS WEDDELLIANA, H. Wendl. in *Flor. et Pom.*, 1871, p. 114, with fig.; *Fl. des Serres*, t. 2000; *Kerchove Les Palmiers* [1878], pp. 90, 94, 336, pl. 40; Beccari in *Malpighia*, i. [1887], p. 443.

Glaziova Martiana, Glaziou ex Drude in *Mart. Fl. Bras. III.*, pars. ii., p. 397, t. 86.

Glaziova (and *Cocos*) *elegantissima*, Hort.

Leopoldinia pulchra, Seemann, in *Gard. Chron.*, 1870, p. 494 [the earliest figure]. *C. H. Wright.*

FIG. 82.—TEMPERATURE INDICATOR.

FIG. 83.—TEMPERATURE INDICATOR IN POSITION.

NEW INVENTION.

THE SIMPLICITY HOLDER AND INDICATOR.

THIS is an invention for hanging thermometers so as to indicate the required temperature of glasshouses, living-rooms, &c., where temperature plays an important part. The holders are so constructed that they will receive any sized thermometer. It may be used in the following manner:—Take hold of the ladder and draw it out, turn the pointers back, and hang the thermometer on the projecting knob in the centre of the disc, and press the ladder to until the side-wires are level with the face of the thermometer, and turn the pointers to the face of the glass; they will then not only indicate the required temperature, but will help to keep the glass in position. For instance, in the forcing season, a vinery is started at a day temperature of 50°, and a night temperature of 45°, all one has to do is to

move the pointers on to the figures, so that the man who is in charge of the house or heating apparatus will know what temperature is required, thus doing away with the plan of writing tickets or labels. The disc at the top also has a pointer, which is moved by the projecting knob that the thermometer hangs on. This is to indicate the degree to which the warmth may run up by sun-heat. These holders can be obtained from Mr. A. Outram, 7, Moore Park Road, Fulham, London, S.W.

FRUIT REGISTER.

APPLE GASCOYNE SCARLET.

ALTHOUGH this is a showy fruit, and the tree a good grower, I have never met with one that bore a heavy crop. Grafted on an espalier tree, some branches fruited well in 1897 in the gardens at Northdown House, Margate, and the fruits were of large size and bright colour, keeping sound till the New Year.

LORD SUDELEY.

A half-standard was one of our heaviest cropped trees here last year, and if not so sweet as most dessert varieties, they were showy on the dessert-table, and in season at an early part of the autumn. By going over the trees at intervals of a week, and gathering those that were fit, its season was much prolonged. Another variety which bore well was Cockle Pippin, not A 1 to look at, but a variety most acceptable when choicer Apples are scarce. *H. Markham, Margate.*

CONTINENTAL NOVELTIES.

NECTARINE FELIX FAURE.

THE well-known raiser of new varieties of *Canna indica*, Crozy of Lyons, has been fortunate in raising a new Nectarine from seed, which, according to the verdict of French pomologists, deserves the widest distribution. The fruit is of a beautiful purplish-violet colour; the pulp very juicy, of a quite peculiar good flavour. It is ripe in the latter half of the month of July. When perfectly ripe, the pulp separates from the stone, but before this period it is more or less of a clingstone.

ARTICHOKE, CONSTANT BEARING OF LOMBARDY.

According to the *L'Horticulture Nouvelle de Lyon*, the firm of Leon Lille, of Lyons, is sending out a variety of Globe Artichoke, that for some years has been grown in the neighbourhood of Milan. This variety differs especially from all other known Artichokes in its comparatively dwarf growth, 2 feet—2½ feet.

The leafage is dark green, the heads long, oval, and quite regular, symmetrical, the bracts destitute of thorns, dark green in colour, excepting at the base, which is violet. It is said to be a great and an early cropper. Seed sown in February and March in heat, soon germinates, and develops under frame culture into robust plants, which transplanted where they are to stand in the month of May, begin to afford heads in August and September.

COLONIAL NOTES.

RUBBER CULTIVATION IN CEYLON.

MR. J. C. WILLIS, the Director of the Royal Botanic Gardens, Ceylon, has issued a circular relating to the cultivation of Rubber-plants, the mode of extracting the juice, and other matters. The chief kinds likely to be useful in cultivation are Ceara Rubber, produced by *Manihot Glaziovii*, Panama Rubber, yielded by *Castilloa elastica*; Para Rubber (*Hevea brasiliensis*), and perhaps African Rubber (*Kickxia africana*). Ceara Rubber grew well in Ceylon, but was found unprofitable. Indeed, the only one that, commercially speaking, can be grown in Ceylon is the Para Rubber (*Hevea brasiliensis*).

Cultural details are given, and the general conclusion arrived at, that after payment of all incidental expenses, there still remains a prospect of a good return on the capital expended.

JAMAICA.

The last issued part of the *Bulletin of the Botanical Department* is taken up with the annual report of the Director on the various gardens under his charge. No fewer than 264,000 plants of various kinds have been this year distributed from the Hope Gardens alone. Referring to Pine apples, it is found that if in the centre of the leaf of the Green Ripley there is a broad red stripe, the fruit will turn out good; in other cases, the fruit goes into holes at the bottom, and is attacked by ants.

SOLANUM WENDLANDI.

This species is one of the most striking of the collection of climbers cultivated by horticulturists in Cape Colony, and it is a new plant out here. I obtained a small plant from Kew about two years ago, from which a large batch of plants has been raised, cuttings of the plant rooting freely. Three of these young plants were planted against a wire-trellis in the open ground in November 1897, and they are now (February, 1898) about 5 feet high, and in full bloom, with about nine trusses on each, some of the trusses being 14 inches across. The plants on this trellis make a splendid sight. It is, I think, likely to become a market-plant at the Cape, being well adapted to the climate. *C. Howlett, Vitenhage, Cape Colony.*

STRAITS SETTLEMENTS BOTANICAL GARDEN.

The Report for 1897 of this garden, by Mr. H. N. Ridley, is now before us. The season seems to have been an average and unremarkable one, save for exceptionally heavy rainfall in certain districts. The Report is, on the whole, satisfactory, various experiments having been made to acclimatise economic and otherwise valuable plants, among them the African Tree-rubber, *Kickxia africana*, which is being carefully tried in the economic garden, Singapore.

AGRICULTURAL REPORTS FROM NEW ZEALAND.

We have received from the New Zealand Department of Agriculture the Reports of the biologist (Mr. T. W. Kirk) for 1893-94, 1894-95, 1895-96, and 1896-97. These four pamphlets have now an additional interest, in that previous to their receipt we had received the news of the death of the author. Mr. Kirk's work is widely known and appreciated, and his place as a biologist will not be easily filled.

MARKET GARDENING.

HARDY PERENNIALS FOR CUTTING.

(Continued from p. 195.)

HELIUM pumilum is another free-flowering plant, indeed, the most profuse of its race, though *H. autumnale* and *H. nudiflorum* (syn. *grandiflorum striatum*) are good. Among Columbines none can equal the well-known yellow-flowered *Aquilegia chrysantha*, its best companions being the hybrids of *A. coerulea* and *A. californica*. These are best raised from seeds, which may be sown in the open, or in prepared soil in beds. If the seeds be sown at once, the seedlings may be planted into permanent positions in the end of August, at which time another sowing may be made to furnish plants to be put out in spring.

A selection of varieties of the "bearded" Irises, *I. germanica*, and allied sections, should be grown, and the following are good kinds: Purple King, early; Princess of Wales, pure white, early; Innocentia, white, later flowering; and flavescens, yellow; Dr. Bernice, crimson and bronze; Pallida, and Pallida dalmatica, the most exquisite pale mauve colour. Gracchus, crimson and white, very fine; Madame Chereau, white, edges of petals pencilled violet, a beautiful form; and Queen of May, soft pink. These not only afford some variety of colour, but also a prolonged season of flowering. The plants may be divided and planted from now to the

end of May; indeed, after flowering is completed is now regarded the best time of the year to replant the whole group of tall Flag Irises.

Pyrethrums in both single and double kinds are useful to the florist and profitable to the grower. By a little extra trouble these may be flowered in spring and autumn, and, as long-stemmed flowers are so much in demand, this is worth doing.

Pæonies are most desirable, but it is now too late to plant these with any hope of success this year. Other useful plants include *Doronicums*, flowering in March and April, *D. Harpur-Crewe* and *D. austriacum* being the best; such species of *Trollius* as *asiaticus*, *europæus*, *Fortunei* fl.-pl., *napellifolius*, and the newer *Orange Globe*. These are best suited for a rather moist spot and retentive soil, and should be planted at once, as they flower in May; but the best time to move these plants is after they have flowered. I would not, however, commend the latter season in the case of field culture, as the plants so treated require attention in watering, and early autumn would be best. *Tritoma Uvaria* may be planted on a limited scale. *Rudbeckia Newmanii* and *R. purpurea* are both free flowering plants, so also is *Centaurea montana rubra*.

Carnations and Pinks need no recommendation from me, but the perennial Sunflowers cannot be thus disposed of, particularly *H. multiflorus* and *vars.*, *H. rigidus*, and *H. Miss Mellish*. Michaelmas Daisies form another important group; a few indispensable kinds are *A. amellus* and *A. bessarabicus*, perhaps jointly the best either for beds or for cutting. *A. acris*, producing a wonderful mass of starry flowers, is splendid for house decoration, but does not pack well. Other kinds are *Novæ Angliæ*, *roseus* and *pulchellus*, *Novi Belgii*, *densus*, *cordifolius elegans*, &c. A few specially good Campanulas are *C. persicifolia alba*, also *C. p. coronata alba*, and the large-flowered "grandiflora;" these, with *grandis alba*, are all good, and if planted on rather moist land may be kept vigorous, and probably free of Thrips that in dry seasons infest them. Unless stated to the contrary, the whole of the plants named are well suited to spring planting and field culture—plants, moreover, that quickly establish themselves, and in many instances provide an early return for the outlay. Many good things that take longer to establish, or are not suited to planting at the present time, have for obvious reasons been omitted. *E. Jenkins, Hampton Hill.*

NURSERY NOTES.

B. S. WILLIAMS & SON.

At the Victoria and Paradise Nurseries at Upper Holloway, a few days since, the collections of *Hippeastrums* and *Cliveias* were in full bloom, and in company with other spring-flowering plants, they made a fine display of colour.

In the house of *Hippeastrums* by far the most noteworthy varieties were some recent seedlings, at present unnamed. The greater number of the older varieties are very large flowered, strong-habited, and brightly-coloured, but they lack the variety that is so necessary in a group of such plants. In form and colour of the blooms the seedlings will afford this. Broadly speaking, the blooms are of less depth, the segments broader, therefore more imbricated, and in place of the self-colours, some are prettily striped in varying degree, and upon different coloured grounds. More than this, several of the newer ones, though not "starers," carry their flowers strictly horizontal, and are so much the more effective. One of them had scarlet flowers striped white, the segments being of more than usual substance, and in our opinion this was as desirable a plant as any we noticed. Another was dull crimson, very prettily veined with slightly deeper colour; whilst a third had large cerise-coloured flowers, veined white. The flowers of the last-named were slightly pendent, but the variety in other respects was a commendable one.

In the *Cliveia*-house were some fine large, profusely-flowered specimen-plants, any one of which was suffi-

cient to demonstrate what an effective plant a *Cliveia* is when in flower, providing liberal treatment has been given it. Each year a few additional seedlings flower, and some of them prove to possess points of quality that go to make them desirable in the collection.

Of the seedlings in bloom at the present time the best is undoubtedly one known as *O. Wrigley*. This plant is a fair-sized specimen, and would appear to be several seasons old; it is remarkably free flowered, and its spikes have umbels possessing eighteen or more large sized finely-coloured blooms. A decided advantage that may be claimed for the *Cliveias*, is the fact that though the plants be moved from room to room (with a reasonable amount of carefulness observed), they remain in flower comparatively for a long season.

In other houses, the stove and greenhouse plants, and Orchids the firm has long been noted for, are looking well, in spite of the building of dwelling-houses that has taken place in the district during recent years. It would appear though, that the fact is foreseen, that sooner or later a move must be made towards a purer air. A small part of the nursery has been ceded for building purposes, and concurrently land at North Finchley, something like 4 miles distant from Upper Holloway, has been obtained.

A few flowers only were to be seen in the Orchid-houses, including *Odontoglossum crispum* and other cool species, also the pretty hybrid *Phaius* × *Norman*. Among the *Cypripediums* were some good varieties of *C. Harrisianum superbum* in flower, and a batch of plants of *C. Mastersianum*. This latter species is very free flowering, and if the blooms are small they are equally distinct. The dorsal sepal is green and white, wider and less deep than in most *Cypripediums*; the petals are dull red, marked with dots of chocolate. Large batches of *Aralias* were about ready to lift from the propagating-case, and young *Crotons* were observed in quantity. Among several species of *Asparagus*, *A. retroflexus arboreus* was conspicuous. This *Asparagus* is destined to become a very popular one for various purposes, and is as distinct from the others as it is beautiful in appearance. *A. virgatus*, *A. sarmentosus*, *A. Sprengeri*, and *A. plumosa*, are all good garden plants. A new greenhouse *Rhododendron* is named *Madame Cuvelier*; it has large widely-expanding white flowers in the way of *R. Fosterianum*.

THE BULB GARDEN.

A YELLOW NARCISSUS DUBIUS.

I HAVE in flower, in a cool greenhouse, a yellow form of *Narcissus dubius*. It does not seem to me to differ in any way from the type, other than that the whole flower is of pure yellow colour. My friend Mr. P. Barr, found the plant in April, 1894, growing in loam a little south of Pont du Gard, and sent me in the following summer a bulb which flowered for the first time this year. The occurrence of the yellow form being apparently very rare, Mr. Barr wishes me to make a note of it. *M. Foster, Great Shelford, March 26.*

SCOTLAND.

THE EDINBURGH ROYAL BOTANIC GARDENS.

THE new conservatories which have been erected at the Royal Botanic Gardens, Edinburgh, were opened to the public for the first time recently. They occupy the site of the old greenhouses to the south of the herbarium and museum, and other ground in the vicinity; and into their construction all the latest improvements have been introduced. The range of glass buildings has a frontage of 340 feet, and the main building, which is on the west side, is open from end to end for that length. At right angles to it, on its east face, are four large conservatories, 64 feet in length by 24 feet in breadth; and rising over the central house is a dome with an annexe, around which the other

buildings group themselves in a pleasing manner. The first of these buildings on the south is devoted to the culture and exhibition of stove plants, the second to Orchids, the third to economic plants, and the fourth to succulents and plants from dry regions.

The entrance porch to the central house is devoted to the exposition of insectivorous plants, which have always an attraction for the public. They include the Sarracenias, different kinds of "fly-traps," and representatives of the numerous family of Sundews. Quite a new system has been adopted in the Botanic Garden conservatories for the last year or two, and that is to set the plant or shrub in the earth and not confine its roots within the limits of a pot or tub. The change has been of the most beneficial kind. Under the dome there are set out in this way large specimen Himalayan Rhododendrons, backed by a grove of Camellias and on each side are beds of Myrtles and Acacias; while on tables round the east wall are pots of hard-wooded flowering plants, such as Ericas, &c., which make an excellent show.

On the west side wall, and depending from the roof, are creeping and climbing plants, the foliage and flowers of which add greatly to the decorative aspect of the place. In the border along this wall there has been placed a fine collection of Cliveia, the dark green foliage and gaudy flowers of which have a striking effect. The collection of Orchids at the Botanic Gardens is of recent origin, and there are to be seen in the two houses at present over 1200 species, and a very beautiful display they make. The stove plants are all planted out, and the effect of this change upon their habit can readily be seen by even the most inexperienced eye. The plants in the economic house include many that are well known in connection with commerce.

One of the most interesting of the greenhouses is that devoted to the culture of plants from arid climes. These include several species of Aloe from America, representatives of the Cactus and Euphorbia genera. There are cool glass chambers provided for the cultivation of filmy Ferns; and on the north end of the range is an old house, which will be reconstructed by-and-by, where is lodged at present the large and fine collection of Masdevallia which was presented to the gardens by the Marquis of Lothian.

When the Palm-house was overhauled and reconstructed two years ago, the large specimen Palms and other trees were removed from the old pots in which they had grown for years, and were set in the earth. There has now been time to appreciate this change, which has quite revolutionised the character of the house. Without exception, the trees and shrubs have thriven marvellously, and are growing with something of the robustness and vigour which they display in their native habitats. Prof. Bayley Balfour's scheme for the improvement and popularising of the gardens and arboretum is not yet completed, but it will have to rest a little, as the money voted for this year has, in a way, been appropriated for the work of reconstructing the greenhouses. There will, however, be enough left for him to enter upon a renovation of the back gardens, where, unseen by the public, important cultural work is done, and to finish off in a suitable manner the ground now being levelled and improved to the south of the Palm-house. The cost of the erection of the new greenhouses has been over £2000. *Scotsman*, March 18, 1898.

SOCIETIES.

LINNEAN SOCIETY OF LONDON.

MARCH 17.—Dr. A. GÜNTHER, F.R.S., President, in the Chair.

Mr. J. Harting, F.L.S., exhibited an egg of the Great Auk (*Alca impennis*) which had just been discovered after having been lost sight of for more than twenty-five years. This, the Troughton egg, was reported to have been broken to pieces through the carelessness of a servant, but was merely cracked, and, having been put aside by the widowed Lady Garvagh, was lost sight of until the present week, when, on the death of her daughter, who was her residuary legatee, it became necessary for the executor, Mr. James Powell, to

make an inventory of the personal effects, and the egg exhibited was discovered by Mr. Harting when examining what remained of the collection, long forgotten and stowed away in a dusty attic.

Mr. Edward Bidwell exhibited photographs of the two eggs of the Great Auk acquired from T. H. Potts, and a water-colour sketch of the Troughton egg made in 1861 before it became the property of Lord Garvagh. This sketch placed its identity beyond doubt.

Mr. Howard Saunders, F.L.S., made some remarks on the N.W. limits of the area formerly inhabited by the Great Auk.

Mr. Carruthers, F.R.S., recalled his acquaintance with Dr. John Fleming of Edinburgh, who died in 1857, and who in 1821 was in temporary possession of a living Great Auk. This bird was allowed to swim in the sea with a cord attached to one leg, and owing to this indulgence eventually contrived to escape. Before another twenty-five years elapsed the species had become extinct.

Mr. Clement Reid, F.L.S., read a paper on "Limnecarpus," a new genus of fossil plants from the tertiary deposits of Hampshire. This new genus occurs in the Oligocene strata of the Isle of Wight and the Hampshire coast. It is closely allied to Potamogeton and to Ruppia.

Prof. E. B. Poulton, F.R.S., F.L.S., read a paper entitled "Natural Selection as the Cause of Mimetic Resemblance and Common Warning Colours." He remarked that the recent attacks upon the theory of natural selection as the explanation of the above-mentioned phenomena render it necessary to reconsider the whole of the evidence. Alternative hypotheses offered in explanation are—(1) the common result of common forces in a single region; (2) evolution producing the same result independently in different animals; (3) sexual selection. The main general aspects of mimicry, &c., their relation to kindred subjects, the most characteristic features which they present, are therefore to be considered in succession, and the attempt made to ascertain whether they best receive an explanation from natural selection or any one of the alternative suggestions.

The chief heads to be considered are:—(1) The relation of these resemblances to others which occur in Nature. (2) The relation of these resemblances between Classes and Orders to those within the limits of a single Order. (3) Resemblances within the Order entirely independent of Affinity. (4) Resemblances not accompanied by any changes in the direction of another species except such as assist in producing or strengthening a superficial likeness. (5) Essential nature of the resemblance: its analysis into the several kinds of effect produced. (6) The forces which act in any animal depend more upon its life-history than upon its locality. Different animals in the same locality are frequently subject to entirely different forces. (7) Resemblances more characteristic of female than male. (8) The space and time relationships of these resemblances. (9) Resemblances between various Orders, &c., produced in the most diverse ways. (10) Resemblance even within the limits of the Order also produced in the most diverse ways. (11) The unproved, improbable hypothesis of the hereditary transmission of acquired characters demanded by the theory of the direct action of external causes.

The discussion of cases under each of these main heads leads to the conclusion that no help is to be derived from any alternative hypothesis, while natural selection in every case offers an intelligible explanation of the known facts. The conclusion to be drawn is that the recent attacks upon natural selection are not warranted by the facts at present known.

MANCHESTER & NORTH OF ENGLAND ORCHID.

MARCH 24.—At this meeting there were present, Messrs. Thompson (Chairman), Ball (Vice-Chairman), Greenwood, Sidebotham, Leeman, Weathers, Backhouse, Stevens, Gent, and Warburton.

Mr. ED. HOLT, Prestwich (gr., Mr. Murphy), showed a most interesting plant, viz., *Cymbidium eburneum*-*Lowianum*, which flowered from an imported batch of *Lowianum*, thus being a natural hybrid. It seemed to have a more floriferous character than the garden hybrids of the same cross which are in cultivation (Award of Merit).

Mr. G. BUCKLEY, Greenfield (gr., Mr. Robinson), exhibited a yellow form of *Cypripedium insigne*, but which was not sufficiently distinct for award.

Mr. J. ROBSON, Altrincham, exhibited several good things, amongst which were a citron-coloured *Dendrobium fimbriatum* oculatum (Award of Merit), *D. nobile Amesiae* (Award of Merit), and *D. nobile nobilium* Cliff var., *D. nobile giganteum*, and *D. nobile nobilium* Weetman's var.

Mr. J. RICHARDSON, Hale, Altrincham, sent a splendidly grown plant of *Cattleya citrina*, with a varietal name of *giganteum*, bearing fine, well-developed flowers.

Mr. J. LEEMANN, Heaton-Mersey (gr., Mr. Edge), sent a nice collection of plants, including *Dendrobiums*, *Cattleyas*, *Cypripediums*, &c. The Committee awarded a First-class Certificate to *Cypripedium Selligerum* majus, undoubtedly one of the finest forms known; an Award of Merit for a pretty *Odonatoglossum Pescatorei*, also an Award of Merit for *Dendrobium* × *Cybele*, and a Cultural Certificate for a splendid plant of *Mesospinidium sanguineum* with about thirty fine spikes of flowers.

Mr. G. SHORLAND BALL (gr., Mr. Hay), sent a few very good things. Especially worthy of notice was his plant of *Dendrobium splendidissimum* Illustre, which received an unanimously awarded First-class Certificate. Showing the eccentricities of Orchid committees generally, this same

variety only received an award of Merit when previously exhibited; time, no doubt, does heal such little discrepancies. Other plants shown by Mr. BALL were *Dendrobium* × *Aspasia*, *D. × rubens grandiflora* (Award of Merit), and a *Cypripedium* seedling (*Veitchi* × *niveum*) (Award of Merit).

Mr. E. J. SIDEBOTHAM (gr., Mr. Shine) received an Award of Merit for *Cymbidium Lowianum* var. *viride*.

The next meeting will be held on Thursday, April 14. P. W.

THE NURSERYMEN, MARKET GARDENERS', AND GENERAL HAILSTORM INSURANCE CORPORATION, LIMITED.

MARCH 31.—The third ordinary general meeting of the shareholders of this Corporation was held on the above date at Simpsons', Limited, Strand, London. We give below a few extracts from the Report, which was read by Mr. Veitch. The figures serve to show not only the growth of insurance in this company, but also what a large quantity of glass devoted to horticulture there is now in the country.

"The hailstorms which occurred during the year 1897 will long be remembered for their extreme violence, for the large area over which they fell, and for the devastation and ruin which they wrought, more than eighty nurseries being very seriously damaged.

On April 16, 1897, severe storms caused considerable damage to glass and crops at Luton, Dunstable, and Bedford, as well as in Lincolnshire, Cambridgeshire, and North Herts.

On June 24, 1897, hailstorms of unprecedented violence occurred simultaneously in Essex, Hertfordshire, and Middlesex, the results being most disastrous at Chelmsford, Ingatstone, Ponder's End, Enfield Highway, Waltham Cross, Enfield, New Barnet, Heston, near Hounslow, and Harrow.

The glasshouses at over sixty nurseries were wrecked by these storms, and crops in several localities were completely destroyed.

Many of the nurserymen, market gardeners, and farmers were not insured, their losses amounting to many thousands of pounds. In Essex alone the damage to glass and crops was estimated at over £50,000.

On the other hand, the owners of thirty nurseries whose glasshouses were severely damaged, had insured with this corporation, who immediately surveyed the properties, assessed the damages, and paid the claims within six days of the storms occurring."

Extract from Chairman's Report:—Premium-income amounted in 1895-96, to £681 1s. 9d.; in 1896-97, to £889 11s. 6d.; in 1897-98, to £1360 17s. 0d. The premiums in 1897-98 are therefore 53 per cent. more than in 1896-97, and 100 per cent. more than in 1895-96.

GROWTH OF BUSINESS.

Period.	Policies in Force.	Square feet Insured.	Value.
End of 1895-96 ...	235	10,408,161	£ 132,215 16 0
„ 1896-97 ...	346	13,886,095	179,366 11 1
„ 1897-98 ...	550	20,098,104	263,590 19 1

CLAIMS PAID SINCE FORMATION.

In 1895-96, two claims, £283 17s. 4d.; in 1896-97, nil; in 1897-98, thirty claims, £1532 17s. 5d. (one claim amounting to £386 1s.). All these claims were settled within six days of the storms occurring.

Of the £399 4s. 4d., formation expenses, £239 4s. 4d. have been written-off, leaving £160 to be written-off in the next two years. The £500 reserve for unexpired portion of premiums is £200 more than the reserve of preceding year, owing to the increase in premium-income. The report was adopted with unanimity. Letters were then read from nurserymen and others, all of which testified to the usefulness of the Corporation, and to the good work already achieved by it.

The retiring directors and auditors were re-elected, and numerous votes of thanks passed, including one to Mr. H. J. Veitch, President of the Board of Directors; and one to Mr. Alex. Jas. Munro, General Manager and Secretary.

THE PEOPLE'S PALACE HORTICULTURAL.

MARCH 31; APRIL 1 and 2.—The usual spring show of this Society took place in the Queen's Hall of the People's Palace on the above date, and proved to be both the largest and best yet held; there being observable a marked advance in the quality of the Hyacinths, Tulips, and Narcissi especially. Everything staged was contributed by the members, for on this occasion there was not a single outside exhibit, and there are yet enough to fill three lengths of tables. It was really and truly an exhibition of East End-grown plants.

Groups of spring-flowering plants arranged on a certain table-space, were very good. Hyacinths, Tulips, Narcissi, Azaleas, and *Dielytras* predominating. Flowering plants in collections comprised *Richardias*, *Azaleas*, *Hotels*, and *Cytisus*; a collection of three foliage plants grown in windows in the City Road, consisted of a fine piece of *Araucaria excelsa*, about 4 feet in height, broad in proportion, and feathered with branches down to the pots;

a most admirable specimen of *Aspidistra lurida variegata*, and an equally fine example of *Ficus elastica*. *Hoteia japonica* and *Dielytra spectabilis* were good in their several classes, and a very fine *Cyclamen persicum giganteum* was also shown in its class. This had been well cared for in the window of a sitting-room. There were nine entries of six pots of Hyacinths, prominent among them King of the Blues, and Grand Maitre, blue; Alba maxima and Mont Blanc, white; Cardinal Wiseman, Fabiola, and Norma, red.

In the classes for a plant of several specified colours there were well-developed spikes. The popular East-end Hyacinth is undoubtedly King of the Blues. Tulips were also good, and such varieties as Kefzer's Kroon, Proserpine, Ophir d'Or, and Golden Prince. White Pottebakker, Vermilion, and Rosa Mundi did the cultivators great credit. Very few double or single Hyacinths were staged; the single forms are decidedly the greatest favourites.

With few exceptions, Crœuses were past their best, but a few very good pots were staged, and also of *Scilla sibirica*. Polyanthus Narcissi were very good, well grown and flowered, and not too much drawn; while Daffodils, single and double, were numerous and well bloomed. The Trumpet Narcissi comprised some of the best varieties, such as Emperor, Empress, Horsfieldi, Golden Spur, Barri, &c.

There were a similar set of classes for dwellers in the more crowded districts, and there were thirteen entries of three pots of Hyacinths, and fourteen of one pot of any colour. The children are also remembered, there being a series of classes for those who are members of the society. All the competitors must be under fourteen years of age. The society grows in membership, and great interest is shown in the monthly lectures. The next is on the 23rd inst., by Mr. R. Fife, of Orpington, Kent, on "Plant Culture." Once a month there is a social meeting of the members, to which they bring anything of interest relating to the work of the society.

ISLE OF WIGHT.

APRIL 2.—The second annual exhibition of Daffodils and spring flowers in connection with the Isle of Wight Horticultural Improvement Association was held at Shanklin.

Mrs. WHITE-POPHAM, who was introduced by the Chairman of the Association, Dr. J. GROVES, opened the exhibition, which was non-competitive, with a few very appropriate remarks. The exhibits were numerous and meritorious.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

APRIL 4.—Mr. W. H. LEES, of The Gardens, Trent Park, New Barnet, read a paper on "Profitable Orchids" before the members of the above Association on Monday evening last, Mr. C. B. Stevens presiding.

An interesting discussion ensued, in which Messrs. Martin, Stanton, Turton, Woolford, and Bound took part. A fine exhibit of Orchids was made, which helped to illustrate many of the remarks made by the speaker. Those who contributed the plants and cut flowers were Mr. Woolford, gr. to ALFRED PALMER, Esq., East Thorpe (Dendrobiums, Cypripediums, Cœlogyness, Odontoglossums, and Oncidium); Mr. J. Pound, gr. to Dr. MAY, Caversham (Dendrobium fimbriatum oculatum); Mr. G. A. PARSONS, Oxford Road (Dendrobiums); whilst Mr. STANTON, gr., Park Place, Henley, exhibited some racemes of Bougainvillea flowers.

TRADE NOTICES.

Mr. H. DUNKIN, who has been gardener for the past seven years at Warwick Castle, and was appointed lecturer on horticulture by the Warwickshire County Council, has taken a nurseryman and florist's business at West Humberstone, Leicester.

GARDENING APPOINTMENTS.

- Mr. THOS. KERR, late Gardener at Woodlawn, co. Galway, as Gardener to Miss FOWLER, St. Anne's, Broxbeth Drive, Sefton Park, Liverpool.
- Mr. A. E. SUTTON, late Gardener to the Earl of CARLISLE, at Naworth Castle, Carlisle, has succeeded Mr. J. Riddell as Gardener to his Lordship at Castle Howard, York.
- Mr. F. JOHNSON, for the past six years Foreman in the Gardens at Elvetham Park, as Head Gardener to VINCENT STUCKEY, Esq., Hill House, Langport, Somerset.
- Mr. JAMES WILLIAMS, Head Gardener for the past five years at Brandon Hall, Coventry, as Head Gardener to C. WADE, Esq., Middleton House, Longparish, Hants.
- Mr. CHAS. DAVENPORT, late of Strawberry Lodge Gardens, Carshalton, as Gardener to Mrs. MATTHEWS, Marshalls Park, Romford.
- Mr. WM. MACKENZIE, Foreman at Oxenford Castle, as Head Gardener to Mrs. MACRAE, Kames Castle, Bute.
- Mr. ALEX. HARDIE, from JAMES DICKSON & SONS' Nursery, Edinburgh, as Head Gardener to G. A. I. ECCLES, Esq., of Darwin, Lancashire.
- Mr. G. KENT, who had just resigned his position as Head Gardener to Earl of YARBOROUGH, Brocklesby Park, Lincolnshire, as Head Gardener to Lord MOUNT-STEPHEN, Bocket Hall, Hatfield, Hertfordshire; and enters upon his duties immediately.
- Mr. J. KEMP, as Gardener to Colonel TUFNELL-TYRELL, Boreham House, Chelmsford.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named: and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending April 2, is furnished from the Meteorological Office:—

"The weather continued cold and showery over the more eastern and southern districts during the earlier days of the week, but subsequently became fine and somewhat milder. In the north and north-west, however, where at first it was mostly fine and dry, the conditions became unsettled, and rain occurred almost daily until the end of the period.

"The temperature was again below the mean, the deficit ranging from 1° in 'Scotland, N.' to 4° in 'Ireland, S.' and nearly all the English districts. The highest of the maxima were registered, as a rule, on April 1, and ranged from 62° in 'Scotland, E.' and 59° in 'England, S.' to 52° in 'England, N.W.' The lowest of the minima were recorded between March 30 and April 1, they ranged from 23° in 'Scotland, E. and W.' and from 25° in 'England, N.E.' and in several of the western districts to 29° in 'England, N.W.' and to 33° in the 'Channel Islands.'

"The rainfall was slightly more than the mean in 'Scotland, E.' and just equal to it in 'England, N.E.'; but in all other parts of the kingdom it was less than the normal, the fall being especially slight over southern and central England and in the 'Channel Islands.'

"The bright sunshine was deficient in all districts excepting 'Scotland, N.' The percentage of the possible duration ranged from 38 in the 'Channel Islands,' and 37 in 'Scotland, N.' to 26 in 'Ireland, N.' 25 in 'Scotland, E.' and 'England, N.W.' and to 23 in the 'Midland Counties.'

"Note.—Two distinct shocks of earthquake were felt at Falmouth at 11.50 p.m. on April 1.

BOOKS: Miss F. B. *The Amateur Orchid Cultivator's Guide Book*, 2nd edition. By H. A. Burberry, published by Blake and MacKenzie, Printers, &c., Liverpool. Price 5s.—B. A. *Fertilisers and Feeding Stuffs*, by Bernard Dyer, D.Sc., published by Crosby Lockwood & Son, 7, Stationers' Hall Court, Ludgate Hill, E.C.; *A Treatise on Manures*, by

A. B. Griffiths, F.R.S., &c., published by Whittaker & Co., White Hart Street, Paternoster Square, E.C.

CAMELLIAS AND AZALEA INDICA: B. China is the native country in both cases.

CARNATIONS INJURED: *Smilax*. The grubs (which had become pupæ when received) appear to be those of the Carnation-fly (*Hylemyia*), so often mentioned in these columns. It is quite possible that spraying the plants with paraffin emulsion might deter the female flies from depositing eggs; at any rate, it is worth trying. Keep some of the pupæ (such as those now sent) in a box, and watch carefully for the appearance of the flies therefrom. When they appear will be the time to spray at once. R. McL.

CINERARIAS: W. H. Excessive use of manures, with the resulting loss of roots, and of healthy colour in the foliage.

CUCUMBERS DISFIGURED AND CHECKED IN GROWTH: W. J. S. Similar to the rust in Grapes, produced by cold air impinging on the moist warm berries. It is not a disease.

FERN PRESSING, &c.: L. Earle. You should enquire of Mr. Upcott Gill, Bazaar Office, 170, Strand, London, W.C.

FIGS: J. H. P. It is very common for forced Figs to cast some of their fruits, but by very careful attention to watering, and in the regulation of the temperature and ventilation, it is possible to prevent them doing so.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—J. Fulton. *Tritonia* (*Ixia*) *crocata* variety.—N. M. We cannot undertake to name your florists' varieties of *Azalea indica*. Send them to some large grower of the plants.—B. A., *Ormskirk*. *Panicum maximum*.—H. B. *Anemone blanda*.—D. J., *Argentine*. 1, *Cereus candicans*; 2, *Opuntia papyracantha*; 3, *Cereus corulescens*. The plants have been handed over to the authorities at Kew.—W. J. 1, *Cupressus macrocarpa*; 2, *Cedrus Deodara*; 3, *Cedrus Libani* probably, but without seeing the trees it is impossible to be certain.—G. D. L. 1, next week; 2, *Rhipsalis cassytha*; 3, *Polypodium aureum*.—M. W., *Grimsby*. 1, *Diosma ericoides*; 2, *Hibbertia dentata*; 3, *Odontoglossum luteopurpureum*; 4, *Polygala Dalmatense*; 5, *Masdevallia caudata* (*Shuttleworthii*); 6, *Dendrobium Pierardi*.—R. A., *Cornwall*. 1, *Epidendrum cochleatum*; 2, *Azara microphylla*; 3, *Podocarpus neriifolia*; 4, *Epidendrum radicans*; 5, *Acacia*, send flowers; 6, *Senecio*, send flowers; 7, *Eranthemum pulchellum*, probably; 8, *Cestrum* (*Habrothamnus fasciculatus*).

PEAS 18 INCHES HIGH IN MARCH: Banks. Very unusual.

PHALÉNOPSIS LEAF: H. G. The injury to the leaf seems due to slugs, the epidermis being absent in parts. You should put the plant under close observation for a time.

TOMATOS: W. C. The leaves are attacked by a fungus (*Cladosporium*). If the Bordeaux Mixture has not been effectual, try sulphide of potassium, 1 oz. in 2 gallons of water. Spray the under as well as the upper sides of the leaves. Burn all affected plants at once.

VINES AND CASTOR-OIL: A. H. Dressings of an oily nature are decidedly injurious to plants when applied to parts of the bark that are not of a corky nature. Your Vine-shoots have doubtless been killed by the dressing, which penetrated and choked the pores of the tender rind and wood. Oils, if saponified, have not this effect. You will get a break, probably, from the older wood.

YOUNG GARDENER: J. W. P. You should be able to obtain a new start in a garden with the testimonial you possess, notwithstanding the lapse of a year or two, the occasion for that being easy to explain; only you must be content to commence low down in the scale, and accept rather low wages for a time. Why not advertise in the *Gardeners' Chronicle*?

Gardeners' Chronicle.

SATURDAY, APRIL 16, 1898.

THE FRENCH ASPARAGUS INDUSTRY.

FEW plants have been more perfected by good culture than Asparagus, and of the twenty known species, the most important one is *A. officinalis*. Wild Asparagus is widespread in France, in the sandy meadow-lands, near the Ocean and the Mediterranean-sea. It has been cultivated from time immemorial, because it is one of the most refreshing of vegetables, from its aroma, savouriness, and its digestible qualities. To succeed in its culture demands only care as to soil, manuring, and preservation from insects. There are not many varieties from which to select; two are preferred in France, that of Argenteuil and the Dutch; the former especially from its succulence, abundant production of heads, and appetising qualities; while commercially it is unequalled. Asparagus-beds may be planted with one-year-old roots, with seedlings, or seed may be sown where it is to remain. When raised as a kitchen-garden crop, the land so cropped is called in France an *aspergerie*. In the southern districts, these areas are sometimes cultivated by the plough; but spade-culture is the commoner method. Perpignan and Toulouse send their Asparagus to Paris as early as in the middle of March; followed by that from Chatellerault and Romarantin, and which contribute in all 670 tons annually. The supply from the suburbs of Paris, of which Argenteuil forms the centre, amounts to about 10,000 tons in the season, that is, from the middle of the month of April till the middle of June—when new Peas appear in the market. One authority calculates that the total yearly consumption of Asparagus in Paris, that of those conserved in tins and bottles included, amounts to 13,000 tons, or about 13 lb. per head of the population.

The seed of the Asparagus, when freed from its pulp by washing, is dried for a fortnight on sheets of paper in a shady situation free from humidity. Then it is placed in paper bags, and if carefully stored it will retain its vitality for three years, but the one-year-old seed is more certain of germination. The seed may be sown in sunny nursery plots of sandy or light soil, well tilled, and from which all large stones and rubbish are removed; manure being heavily applied, the plant being a gross feeder. About one cubic yard of horse-dung or sheep's manure, or less of night-soil, may be used on four perches of land. Others employ pigeon's dung, the so-called Peruvian-guano, and wood-ashes, mixed well together, and applied so as to have a layer of fertile soil 6 to 8 inches thick. Sowings are made in the month of April, placing, just as in a field-trench, the

seeds one by one, covering lightly with the earth, and then with straw. In the course of a month the plants will appear as thin green spikes, but they will soon branch out, and in the course of a month it is time to thin them to 4 inches apart, removing those that are sickly or crowding too close. It is well to water the soil before thinning the plants, as so doing facilitates the operation. During the summer weeds must be kept down, and in the autumn when the stems are yellow and 2 feet high, cut these down and remove them. In the winter nothing can be done, and the plant is not injured by frost. To raise Asparagus plants for setting out in beds, is an important industry in itself; and the roots, called *griffes*, are sold at 80 francs per 1000. One of the leading Argenteuil nurserymen has also on hand some 400 varieties of Strawberries, 100 of Figs, and 1000 kinds of Vines; this is merely to give an idea of the trade in these special cultures.

The permanent Asparagus plantation requires a light soil free of stones, and well drained, naturally or artificially. In January, plough down 24 tons of farmyard, or proportionally water-closet manure known as *gadone*, per acre, and apply manure heavily the first six years, and afterwards every alternate year. In March, make a trench, either with spade or plough, 20 inches wide and 6 inches deep; and at a distance of 28 inches from the back of this trench open another, so that the plant-rows will have a total of 48 inches apart. The intervening space will be occupied by the earth from the trench. In the bottom of the trench, upon some night-soil compost, woollen rags, hair, or bits of old leather, place in April the young roots or *griffes* 40 inches apart, and cover with 2 inches of the friable soil or mould, and be careful not to lay the shaggy roots upside down. In due course, plenty of branches will be thrown out, and then keep the plants clear of weeds. In autumn, cut down the yellow stalks, make them into a bonfire in a reserved spot, and cover the plant with farmyard manure, not as protection, but for fertilising purposes. In the next year, hoe down more of the earth between the rows, so as to mound-up the plant. Many growers at this period stake the stems in June, or tie them to a galvanised iron-wire running above the trench. All this is done to prevent the breaking of the stem at the junction with the root. To eradicate the weeds is all that is required till the autumn; then cut down the yellow stems and cover the plant spot with farmyard manure. The Germans employ 140 lb. of common salt per 1000 plants, the moiety in March and October, and by this greater productiveness in the plants, and more delicacy of flavour is imparted to the heads.

It is during the third spring that the first cutting commences. In March, earth-up by plough or hoe to 8 inches, so as to force the stems to become blanched, and arrive just at the surface white and tender. If allowed to come through the earth, the ends will turn green, and be harder, and less delicate. At Argenteuil, the cutting of Asparagus-shoots is far too delicate a matter to entrust to strange hands, so the whole family of the cultivator performs that skilful task. It is now the middle of April, and at four in the morning the gatherers are in the fields. They have a small hand-basket, and a larger one strapped to their back, containing a cavity at the bottom in which their breakfast is stored. Some workers carefully remove with the hand the earth from about the plant, snap off the desired shoot, and replace the soil in position; others have a

special instrument, a large fork, with two prongs at one end to remove the earth, and at the other is a knife with a thin blade to cut off the "*turion*." The small basket when filled is carefully emptied into the larger one; the latter is to carry home the produce. The cutting must be over ere the dew disappears. On arriving at the shed, the work commences of sampling the Asparagus into three categories, which are passed respectively through as many different-sized moulds on a bench; then the bundles are tied with two Osier-twigs, and the root-ends of the stalks made even with a hook-knife. Next, the bundles are placed in a trough to wash off any earth that may remain attached; when taken out, they are allowed two hours to drain and dry. Ultimately, they are brushed. Later, a cart arrives to take the produce to the Halles Centrales, or Central Market of Paris, where it arrives at midnight; the owner has preceded the Asparagus, and selected his few yards of space whereon to sell his produce (between 4 and 7 o'clock), in lots of three bundles at once, but all must be cleared away before 9 o'clock in the morning. The circumference of a bundle of white Asparagus is 20 inches, its weight 6½ lb. The weight of a green-top bundle one half less. Price per bundle 1½ to 7 francs.

To estimate the profit per acre of Asparagus culture, a few accessories must be remembered. The season—two months—extends from the middle of April till the middle of June. The first crop of a new plantation is cut in the third year; only two or three stalks are removed, so as not to weaken the plant.

From the fifth and sixth years, the *aspergerie* will be in full productive power, and can so continue for ten or twelve years. When then broken up, the ground cannot be again occupied with Asparagus till after the lapse of ten years. When in full bearing capacity, one clump of roots yields one bundle of shoots in the two months. The number of plants per acre ranges from 1200 to 4000; the expenses of culture amount to 400 francs, and the sales to 2000 francs. If early Potatoes, Cabbages, Haricots, Gooseberries, &c., be raised in the spaces between the rows of Asparagus, their sale must count. At Argenteuil the Asparagus-rows alternate with Vines, but the latter do not like the union. The wine, a small brand, may realise 400 to 600 francs per acre, and the Asparagus from 800 to 1600 francs, or a combined minimum yield of 1,200 francs to 2200 francs per acre. Within the last half-century, the Asparagus trade of Argenteuil has risen from 30,000 francs to 2,000,000 francs.

Not much attention is given to forcing Asparagus, which was first made known in 1735 by La Quintinye, raising it at Versailles for the Royal table, on hot-beds and under glass. It is very dear—30 francs the bundle—but lacks the aroma and the delicacy of the open-air Asparagus. Its duration, too, is short in the market.

The success of Asparagus-culture at Argenteuil, a city suburb, is attributed by best judges to the manure employed—the *vidange* or night-soil of Paris. Asparagus is eaten in France cold as well as hot: the latter with white sauce; if cold, with oil and vinegar. It is a favourite dish with convalescents, enabling them to pass from a liquid to a more substantial régime. In cardiac affections it is said to act as a sedative, and reduces the heart palpitations, like digitalis, without irritating the stomach. Asparagus is said to be bad for patients recovering from articular rheumatism, as it tends to

bring on a relapse. It is very diuretic. The cause of the foetid odour that *Asparagus* imparts to urine, within less than an hour after eating, and continuing for seven or eight hours, has never been explained by science. A little essence of turpentine poured on the foetid urine produces an odour analogous to that of Violets. The roots of *Asparagus* have always made a popular soothing drink for the sick, while the green tops are utilised to make syrups, and to do duty as green Peas. The immediate principle of the plant, known as "asparagine," is not peculiar to *Asparagus*, as it is to be found also in several other vegetables. *Edward Conner.*

ORCHID NOTES AND GLEANINGS.

THE number of *Lindenia* for February and March of this year contains figures and descriptions of the following Orchids:—

CATTLEYA MENDELI, EMPRESS QUEEN.

A very handsome variety, with pale or deep rose-coloured segments, very broad petals; a lip, white at the base, with yellow lines in the throat, and a broad undulate anterior lobe of a rich magenta. Lucien Linden & Co.; t. DC.

VANDA × MISS JOAQUIM.

A hybrid, raised at Singapore by Miss Joaquim. See *Gardeners' Chronicle*, 1893, vol. xiii., p. 740; 1897, vol. xxi., p. 410; t. DCII.

ONCIDIUM BATEMANNIANUM.

Sepals and petals shining brown, crest of the yellow lip richly spotted with purple spots; t. DCIII.

ODONTOGLOSSUM THIBAUTIANUM, L. Linden.

A reputed natural hybrid between *O. crispum* and *O. odoratum*; t. DCIV.

SACCOLABIUM GIGANTEUM VAR. PETOTIANA.

A pure white form of this species, remarkable also for the large size of its flowers; t. DCV.

CATTLEYA HARDYANA × VAR. REGINÆ, L. Lind.

Cattleya Hardyana, one of the most brilliant of the genus, is a natural hybrid between *C. aurea* and *C. gigas*. The segments are straw-coloured, the lip reddish-crimson, throat with two yellow blotches. Messrs. L. Linden et Cie.; t. DCVI.

CYMBIDIUM PENDULUM, Swartz.

This is the plant long known in British gardens as *C. aloifolium*; t. DCVII.

LÆLIO-CATTLEYA "PALLAS" VAR. INVERSA.

The original Pallas was the result of a cross between *Lælia crispa* and *Cattleya Dowiana* effected by Messrs. Veitch. The present variety raised by M. Mantin, is stated to be the inverse cross; t. DCVIII.

HYBRID NOMENCLATURE.

A writer in the *Lindenia* protests, and not without reason, at the inconvenience of the present system of naming hybrids. Cattleya and *Lælia*, most people think, form one genus, and therefore there is no need for *Lælio-Cattleya*, and no necessity for adding "Brass" to it. It is very difficult to persuade people that it is wisest not to attempt to make the name more than a name. The universal tendency is to make the name descriptive—to make the name play a double part. The result is that one part is generally badly done. Secondary crosses should, in our opinion, always receive vernacular names; and moreover, we think it would be better if primary artificial crosses were similarly named.

"DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDÉES."

The following species are figured in the January number, which has just reached us:—*Bifrenaria Harrisoniæ*, Rehb. f.; *B. tyrianthina*, Rehb. f.; *Cattleya Patrocini*, St. Léger; *C. Mantini*, G. Mantin; *Cymbidium Tracyanum*, Hort.; *Cypripedium Arthur-*

ianum, Rehb. f.; *Dendrobium fimbriatum*, Hook.; *Lælia purpurata aurea*, Rehb. f.; *L. anceps Schroderiana*, Rehb. f.; *Miltonia Peetersiana*, Rehb. f.; *Odontoglossum Rossii* albena, H. Will.; *O. nevadense*, Rehb. f.; *Warszewiczella cochlearis marginata*, Cogn.; *W. c. Peetersii*, Cogn.

LÆLIO-CATTLEYA × SIR WILLIAM INGRAM.

This hybrid form appears to be one of the handsomest of spring-flowering Orchids. It flowered for the first time in the month of April, 1896, and it is again in flower in the garden of the raiser, C. L. N. Ingram, Esq., Elstead House, Godalming. It is the result of a cross of a fine form of *Lælia purpurata* with *Cattleya Dowiana aurea*, and the bloom is very charming and brightly coloured, showing distinct traces of *C. D. aurea* in the lip, but scarcely any in the sepals and petals, which are of a clear rosy-lilac hue. The lip is orange-coloured at the base, and heavily marked with reddish-purple bands. The front lobe is of a bright purple colour, that merges into claret colour in the centre, the whole having a lavender coloured margin.

CATTLEYA × CECILIA.

This pretty hybrid between *Cattleya Lawrenceana* ♀ and *C. Trianaei*, raised by Mr. T. W. Bond, gr. to C. L. N. Ingram, Esq., Elstead House, Godalming, was first shown at the meeting of the Royal Horticultural Society on November 12, 1895, and another variety of it named "elata," was shown on March 9, 1897, the latter being much better in form than the one previously shown. A grand flower of it has been received from Mr. Bond that serves to show the amount of progress that is due to cultivation. The sepals and petals are of a bright rosy lilac; the lip, which partakes in form of that of *C. Lawrenceana*, is of a light rosy-tint at the base on the exterior, and cream-white in the interior. From the base some dark red lines radiate, which in the middle area change to yellow and again to white as the front is approached. The front lobe, and edges of the side lobes, have a rich amethyst-purple tint, and the spaces between the veining are lighter in colour. As in the varieties formerly shown, there is a distinct resemblance to *Cattleya labiata* Luddemanniana, or speciosissima as it is often called.

WOOD-ASHES.

WE learn from a report by R. Harcourt, B.S.A., Assistant Chemist, O.A.C. Guelph, that there is a growing interest in the subject of wood-ashes, and their use as a fertiliser. This is largely owing to the fact that long cultivated lands are beginning to show a lack of fertilising constituents that are supplied by ashes, and to a desire on the part of the cultivator of the soil to increase and improve his crops.

The growing plant gathers all its mineral constituents from the soil in which it lives, and these, not being combustible, are left as ash when the plant is burned; consequently, the ash must contain all the mineral constituents that are essential to growth. These are potash, phosphoric acid, lime, magnesia, iron, and sulphur. These substances form a very small part of a plant, yet without them no plant could grow and produce seed; in fact, they are indispensable to life. Of the six essential plant-food substances named, potash and phosphoric acid are the most important, not only because they are taken up by the plant in large quantities, but also from the fact that our average soils do not contain them any too abundantly. Wood ashes, therefore, are usually valued according to the amount of those two constituents which they contain. Although potash and phosphoric acid are the most valuable plant-food substances in ashes, yet ashes also contain large quantities of lime, which is of considerable value to the growing plant. Lime is usually present in most garden soils in sufficient quantities to supply the wants of plant-growth, yet its application may produce marked effects. By acting chemically on certain constituents in the soil, plant-food, especially potash, is brought into an available form. It neutralises the free acid of the soil, and thus helps along the process by which vegetable matter is changed

into a form in which the plant may make use of nitrogen. It also tends to improve the mechanical condition of both clayey and sandy soils.

The amount of these fertilising constituents contained in an ash will vary according to the source from which it is derived. The ash from young branches will be richer in potash than that from the older parts of the tree. Different soils will supply varying quantities of potash, phosphoric acid, and lime. The following table gives the composition of a few of the more common ashes analysed by M. Harcourt. The figures given express the percentage of the various constituents in the dry ash:—

Constituents in Wood-ashes per Cent.

Ashes from—	Potash.	Phosphoric Acid.	Lime.	Magnesia.	Iron.	Sulphuric Acid.
Maple ...	9.31	2.03	45.24	1.14

The figures show clearly why ash buyers are so anxious to get black ash or swamp Elm ashes, but at the same time, it must not be forgotten that these ashes are very light and bulky; consequently, there may be more potash in one measured bushel of hard Maple-ash than in the same bulk of swamp Elm-ash. The hard woods contain a larger quantity of phosphoric acid than the soft woods. Cedar, as would be expected, is poor in both potash and phosphoric acid. The best way to ascertain the true value of ashes is to note the increased yield when they are applied to crops requiring potash, such as Potatoes, Carrots, Grape-Vines, and fruit-trees generally.

The caring for and application of ashes must receive special attention. If not properly stored while accumulating, much of the soluble plant-food will be lost by leaching. If not applied to those plants which are in special need of potash, no noticeable results may be obtained. Further, if mixed with farmyard or stable-manure they may do more harm than good, because they tend to liberate, as ammonia, the nitrogen of the manure. If we may judge by the amount used by fruit-growers in the best fruit districts of the United States and Canada, they are fully aware of the value of wood-ashes in the orchard. *J. J. Willis, Harpenden.*

KEW NOTES.

CYTOSPERMA AFZELII.—This is a new Aroid from Old Calabar, which is now flowering for the first time in a stove at Kew. It has a fleshy rootstock, and numerous dark green glossy leaves from 2 to 3 feet high, the petiole angular, and clothed with short spines; the blade sagittate, 1 foot long and 6 inches wide, the basal lobes 6 inches long; scape erect, 3 feet high, spiny, like the leaf-stalks; spathe erect, ovate lanceolate, half folded at the base, 8 inches long, 3 inches wide, coloured greenish-yellow with broad irregular streaks of purple; spadix, thick, 2 inches long, erect, black-purple, bearing male and female flowers mixed as in *Anthurium*. Kew is indebted for plants of it to Mr. Holland, Curator of the Botanical Station at Old Calabar, who wrote that it grows abundantly in swamps there. He also sent a photograph which shows the leaves and scapes about 7 feet high, and the spathes correspondingly large. For tropical aquaria this ought to prove a striking plant. A figure of it has been prepared for the *Botanical Magazine*. The genus is composed of about ten species, distributed over the tropics of Asia, Africa, and America. *C. lasioides* is an old inmate of the Aroid-house at Kew.

ALOE CONCINNA.

Several plants of this prettily variegated little Aloe are now flowering in the Kew collection. It was

named and described by Mr. Baker in the *Kew Bulletin* in 1895, from a plant received in 1884 from Sir John Kirk, when at Zanzibar. The stem is a quarter of an inch in diameter, about 1 foot high, clothed nearly to the base with leaves which are 5 inches long, 1 inch wide, and one-third inch thick, recurved at the apex, the margins armed with white deltoid teeth, the whole surface glaucous green, copiously

It has tall, leafless, flattened pseudo-bulbs, 3 to 4 feet long, $\frac{3}{4}$ -inch wide at the top. The young stems bear dark crimson leaves, which change to green with age, when they measure 6 inches in length by $2\frac{1}{2}$ in width. The flowers are on slender pedicels 4 inches long; sepals and petals linear, spreading, $2\frac{1}{2}$ inches long, coloured greenish-white; lip white, three-lobed, the central lobe narrow and horn-like, the laterals ovate.

Oregon, where this plant is common in Pine-swamps; they were planted in pans of leaf-mould and sphagnum, placed in a greenhouse, and watered often. Each tuber produces a single leaf, which has a stalk an inch long, an ovate-cordate, ribbed, dark green blade 2 inches long, and an erect scape 3 inches long bearing the daintiest of rose-pink flowers with the pose of a *Cypripedium*, the lip being curiously pouched, with an apron-like front-lobe spread over a pair of projecting horn-like spurs. A pan of about a dozen plants in flower is charming. It is not easily kept from year to year under cultivation, but it appears to be abundant in the United States, and is offered cheap by some of the nurserymen there.

SOLANUM WENDLANDI.

The value of this as a decorative climbing stove-plant is being gradually recognised. It is quite at home on the roof of the Water-Lily house at Kew, where its merits were first revealed, and where it flowers freely during the summer. The following note from Mr. C. Howlett, Uitenhage, S. Africa, shows its behaviour there:—"Two years ago you sent me a small plant of this, from which I have propagated a large batch, as it roots very freely here from cuttings of the green wood. Of these young plants I planted three in the open ground against a wire trellis last November, and in three months they have covered the trellis 5 feet high, and are in full bloom, averaging ten trusses to a plant. Some of the trusses measure 14 inches across. It is a splendid sight, and is admired by all who see it. I think this plant is likely to become a great favourite out here, especially as it proves to be so well adapted to the climate. Everybody wants to know where I got it, and of course I tell them the Royal Gardens, Kew, where all the good things come from."

THE MELON-PEAR.

Fruits of this are now being sent to the English markets from the Canary Islands, where it appears to grow and fruit freely, the fruits being as large as turkey's eggs, very fleshy and juicy, seedless, sweet, and palatable, having the flavour of a Melon with a slight acidity. They are smooth, amber-yellow, with irregular purple streaks about the base. Attention was called to this plant in the *Gardeners' Chronicle* for March 10, 1888, where it is figured under the name of *Solanum guatemalense*. Plants were obtained and grown at Kew, where it proved to be the *S. muricatum* of Aiton, a Peruvian species. At Kew it did not grow well either against a wall, in the open, or under glass, nor have I heard of its proving a success anywhere in England. It is said to be cultivated extensively in the highlands of Guatemala and in California, plants 4 feet in diameter producing 100 to 150 fruits. It has been described as one of the best of fruits when properly grown. Directions for its cultivation were given in the *Gardeners' Chronicle*, April 21, 1888. I lately received a fine fruit from a correspondent in Liverpool, where it was offered for sale in the market. W. W.

FURCRÆA GIGANTEA VAR.

I SEND by same post photographs of two plants growing in the Natal Botanic Gardens, which were received here in 1882 from Mr. Louis de Smet, and were planted out-of-doors early in 1884. They were received under the name *F. Lindeni*, and on referring to Mr. Baker's monograph of *Amaryllidæ*, I find that this plant is said to be a variety of *F. cubensis* with variegated leaves, but a comparison of the measurements of *F. cubensis* given in that work, with those taken by myself of our plants, will show that our plants are certainly not *F. cubensis*; the measurements are as follows:—

<i>F. cubensis</i> .	Our plants.
Trunk, 2 to 4 inches thick.	2 feet 5 inches.
Leaves about 30 in rosette.	140 to 150
" 2 to $2\frac{1}{2}$ feet long.	8 feet 6 inches.
" 3 to 4 inches wide in middle.	6 to $7\frac{1}{2}$ inches.
" $1\frac{1}{2}$ inches wide above base.	3 to $4\frac{1}{2}$ inches.

I have therefore come to the conclusion that our plants are not *F. Lindeni*, but a variegated form of *F. gigantea*, with the description of which plant they

FIG. 84.—FURCRÆA GIGANTEA : VARIEGATED FORM.

spotted with milk-white spots. Scape slender, erect, 6 inches long, bearing a dozen or so flowers on short pedicels, the tube nearly 1 inch long, and coloured red, white, and green. The plant is decidedly ornamental, and it differs from all other variegated Aloes in the loose arrangement of its leaves, their form, and the distinctness of the spots.

EPIDENDRUM NOCTURNUM.

A plant of this, received last year from Demerara, is now in flower in the tropical Orchid-house at Kew.

The flowers are fragrant, especially at night, hence the name. This species is said to have been one of the first Orchids introduced into European gardens. It is widely distributed in central and South America and the West Indies. A small form of it is represented in the *Botanical Magazine*, t. 3298.

CALYPSO BOREALIS.

Several panfuls of this pretty little terrestrial Orchid are now in flower in a cool-house at Kew. The tubers were imported a few weeks ago from

more nearly agree. The reason, however, for my having the photographs taken is the peculiar way in which both these plants have produced their flowers and seeds. Instead of "poling," as it is called by the growers of the plant for its fibre, i.e. throwing up a peduncle of 20 to 40 feet in length from the centre of the rosette of leaves, and thus preventing their further production, our plants about two years ago commenced to throw off from the axils of the lower leaves a number of slender peduncles, which reach from 4 to 7 feet in length, and bear numerous flowers and seeds; and in addition to this, a few suckers are produced on the bare stem of the plants. I do not know whether this mode of inflorescence is common in the genus or not, but should be pleased if this short notice may be the means of eliciting information on the subject. As will be seen by fig. 84, the plant is a striking object, and the variegation of the leaves is very conspicuous; but it is somewhat unfortunate that both plants will most likely have to be removed to make room for our new Jubilee Conservatory. I shall, however, if at all possible, have one at least of them left, as it will be interesting to myself, and doubtless to others also, to know how long they will continue to grow without throwing out the central peduncle, which would notify their approaching end.

J. Medley Wood, Natal Botanic Garden.

THE HORSE-CHESTNUT.

M. E. ROZE recently contributed to the Société Nationale d'Horticulture de France a paper on the Horse-Chestnut and its second flowering, the substance of which is here reproduced. M. Roze remarks that:—"This ornamental tree does not appear to have been known to the ancient Greek and Latin authors; it is mentioned for the first time in the Commentaries of Matthioli, who received from Constantinople, about 1550, a branch bearing fruit.

Matthioli gives a description and illustration showing fanciful flowers, and this design was reproduced by other botanists for more than a century. The flower, in fact, was not really known until much later. Charles de l'Escluse, who gives interesting facts about the Chestnut (*Rariorum Plantarum Historia*, 1601), and who had planted one in Vienna, Austria, the development of which he watched, expresses his regrets at having been obliged to quit this capital in 1588, when his tree, then twelve years old, had not yet bloomed. He said that he had vainly besought his friends, who accompanied the ambassadors of the Emperor of Austria to Constantinople, to send him some flowers; he had only received one Chestnut without its spiny husk, and it was only in 1587 that the learned Wexius brought him a perfect fruit from Byzantium.

De l'Escluse, in his description of the Chestnut, does not then speak of the flowers; but he presumes that it must be a very large tree, and remarks that it bears frost very well, and bears shade and damp as does the Plane. "In autumn," says he, "when the tree has lost its leaves, all the branches are seen to terminate in turgid buds, ready to open, covered with gum, to which gnats and other insects become attached; these buds open at the beginning of spring, so that the leaves appear early." Thus the Chestnut was cultivated first in Italy, where Matthioli resided, and was certainly found also in Austria, later on, by De l'Escluse.

In 1650, Jean Bauhin (*Historia Plantarum Universalis*, Yverdon, 1650) also laments his ignorance of the flower of the Chestnut. But he mentions having seen in the Grand Ducal Garden, Florence, a Chestnut from which he gathered a fruit with its prickles. He adds, that it was a rather large tree, very bushy, and that Zwinger had observed it between Padua and Verona. This clearly proves that the Chestnut was grown in Italy as early as the middle of the seventeenth century.

In France it was already known. Duhamel du Monceau (*Traité des Arbres et Arbustes*, 1755) says:—"It is considered certain that this tree was brought from the East in 1615 by a Parisian collector named Bachelier. What is yet more certain is, that the Chestnut, under its first name of Castanea

equina (Horse-Chestnut) figures in 1636 among the plants cultivated in the Jardin Royal des Plantes Médicinales (now the Natural History Museum), according to the Catalogue published at that date by Guy de la Brosse. It is to be believed that the fruits of this Chestnut-tree served, consequently, for its multiplication in France.

As to the first name of Horse Chestnut (*Châtaigne de Cheval*), given to the fruit, Charles de l'Escluse tells us that it originated with the Turks, who find it of use for broken-winded horses or those with a cough. Tournefort gives a good figure of the flower of this tree (*Institutiones Rei Herbariæ*, 1719), which he names *Hippocastanum vulgare*; he calls it in French *Marronnier d'Inde*. Linnæus, later, gave it in his turn the name of *Æsculus Hippocastanum*, the scientific name actually in use.

THE SECOND FLOWERING OF THE HORSE-CHESTNUT.

So far, there has been no mention of the second flowering of the Chestnut. Duhamel du Monceau, in his above-mentioned *Traité* (1755), speaks thus of it—"The *Marronnier d'Inde* has much increased in the parks, but is not found in the forests; we have planted it in clumps in the woods, where it perished. Nevertheless, it succeeds quite well planted in quincunx in fresh earth, and without being cultivated. It is a very large tree, which is very acceptable in gardens during the month of May. . . . It is lopped and cut with the pruning-hook. Thus are found those beautiful walks which we can but admire in the gardens of the Château des Thuilleries et du Palais-Royal." This author continues: "this tree is only pleasing in spring; the heat of the month of June causes the leaves to turn yellow, some of which fall with the fruit after the month of July."

Now one botanist, Fabregeon, had fifteen years earlier already said: "The *Marronnier des Indes* flowers and fruits in April and May, and sometimes in September and October; these fruits are only ripe in autumn—fruits forming in autumn are always abortive. Nothing is more common in all the environs of Paris, it multiplies from seed and grows without cultivation" (*Description des plantes qui naissent ou se renouvellent aux environs de Paris*, 1740).

It is evident from these two extracts how widely spread the planting of the Chestnut had become in Paris and the environs in the first half of the 18th century. But Fabregeon tells us that this second flowering had already been noticed, although it seems not to have yet attracted the attention of the Parisian florists.

The predominant idea respecting the premature fall of the Chestnut leaves seems to be the result of the allegations of Duhamel du Monceau—that it is the heats of June which are the cause. There would thus be a sort of burning-off of the foliage. But why should the Chestnuts of the boulevards and squares of Paris be more subject to this than those in the country, the leaves of which are hardly browned at the edge when those in Paris are already fallen?

It must be remembered that the Parisian Chestnuts are usually earlier than those outside the city. It must always be considered, too, that Chestnut leaves, as I am assured, are very liable to the disease of browning. The slime fungus, which is the exciting cause, is increased by the plasmodia or microscopic cysts which the wind carries among the trees with the dust of the soil, and which penetrate little by little into the leaflets on which it produces brown spots, ultimately affecting all the blade as well as the veins; it even attacks the petiole, on which it forms brownish marks. The affected petioles wither in turn, and owing to the mortification of the tissues at their point of insertion, fall one after another; soon followed by the petiole, which is detached from the tree by the same cause. The Chestnut is thus stripped after July or August, being yet full of elaborated sap for which there is no use. It is then that the buds are stimulated to premature energy, they open and put forth young leaf-shoots, terminated by racemes of flowers, which surprise us by opening at a season other than that of spring.

This phenomenon of the second flowering is not rare in Paris, as many Chestnuts re-bloom in

September on the boulevards. It is credible that the leaves of these Parisian trees are more easily and sooner affected than those of suburban Chestnuts. This may be partly due also to the precocity of the first foliage, and then to the fact that currents of air are more frequent in the streets of the capital than in the open country. In any case this leaf-destruction is not the result of sun-burn in June, as Duhamel du Monceau believed; but must be attributed to the vigour of the browning disease, which, under certain circumstances favourable to it, is sometimes capable of wide extension.

FLOWERING PLANTS FOR EASTER DECORATION.

EASTER is a season in which there is much demand upon private gardening establishments, by reason of the extra furnishing of mansions generally practised, and the decoration of churches. Easter has now passed, and my object in writing is to mention briefly a few of the many plants which, if forced mildly, are useful at this period, and which I may say were in flower in these gardens on Easter Day. Our well-known friend, the white Arum, must be mentioned, although it is so well known, and is popular everywhere. We do not plant out our stock, as is so frequently done where large quantities are grown, but at the end of August or early in September we pot-up the strongest crowns into 7, 8, and 9-inch pots.

I should be lacking in discrimination if I omitted to mention next the *Azalea indica* Deutsche Perle, which, introduced some years since, has established a reputation for itself which is seldom accorded a plant so unanimously. In regard to this plant, the difficulty is, not how to get it into flower, but how to prevent it flowering. We have quite a number of plants of this choice variety, and have been cutting flowers from them since the end of October last. This Azalea, like all others, is seen at its best when associated with Palms, Bamboos, or other graceful plants.

Viburnum Opulus (Gueldres Rose), and the more compact-growing species, *V. plicatum*, are two subjects of shrubby character, that are eminently adapted for church decoration. The plants are easily forced, and the flowers last a long time in a good state if kept in a cool, well ventilated structure.

Another flowering shrub which is invaluable, and at present is in full beauty, is *Spiræa confusa*. This is wonderfully free flowering, and though it does not last so long in a useful state as the former, it possesses a charm which is unsurpassed.

Writing of this genus, I must not overlook other well-known species, and I have no hesitation in placing the older form at the top of the list, viz., *Spiræa japonica*, as this for general purposes is all that is required. When well-grown, every plant forms a picture, which requires no bolstering up to make it perfect. *S. astilboides* is a stronger-growing variety, and certainly useful; as also is *S. multiflora compacta*; and the latter, especially in a cut state, is very pretty, but as yet they have not displaced the old *Hoteia*, or *Astilbe japonica*. *Staphylea colchica*, though somewhat less known, should be included in every collection of spring-flowering shrubs. The individual flowers closely resemble those of the Mock Orange (*Philadelphus coronarius*), and the plant has to be recommended more as a means of supplying flowers for cutting than as a decorative-plant; for, unless in exceptional instances, the general appearance is stiff. Lilac Charles X., and *L. virginalis*, preferably the latter for this season, are two handsome shrubs, useful alike as decorative plants, and for cutting from.

The sweet-scented Lily of the Valley, and the *Deutzia gracilis*, are probably included in every collection of spring-flowering plants. They readily associate with most other plants; to whatever purpose they are used they never seem out of place. The same remarks apply to Cyclamen, Freesias, Primulas, Hyacinths, Narcissus, &c., all of which are at present in flower. Many of the softer shades of colour in the Indian Azaleas, when a little tone is required, can be used with considerable effect, as also can *Azalea mollis*; while, if yellow is appreciated,

nothing can replace *Cytisus racemosus* and *C. r. elegans*.

In preparing plants for any system of decoration it is of the utmost importance to have the pots washed scrupulously clean. Any sticks to be used should be neatly pointed and painted, all soil surfaces covered with fresh green moss, and the plants freed from any bits which might detract from their appearance. *J. F. McLeod, Rochester.*

"LA MAISON RUSTIQUE."

CAROLUS STEPHANOS, the author, or at least the compiler of the *Book on Gardening in France*, reviewed by Rev. George Henslow, is doubtless the same person with Dr. Charles Stevens, the originator and part author of *La Maison Rustique*, a work devoted to the elucidation of everything connected with French country life in the sixteenth century. Stevens did not live to see his work completed, and it was left to his son-in-law, Dr. John Liebault, to carry forward to a conclusion his labours. It would appear that the book was first published about the year 1564, and up to 1582 it had passed through several editions.

The one with which I am acquainted is that of 1586, a large octavo of nearly 1000 pages, to which is appended a pamphlet on *Wolf Hunting*. The work was early translated into several languages, but Liebault was so disgusted with the imperfections of these that in this edition he mentions his purposing to undertake a translation of the work into Latin in order that people of other countries might be able to peruse his writings free from mistakes. As a complete work it did not appear in England until the year 1600, when, by the title of *The COUNTRY FARMER*, a complete edition, translated by Richard Surfleet, was issued. On comparing this with the original, it is found to be so full of mistranslations, that one cannot be surprised at the mild anger of its part author. Markham's edition of 1615, with some additions, is the same as the above.

In France, the popularity of this book seems to have continued for a long time, and when at length it became antiquated and out of date, it was in last century replaced by a work of a kindred nature called *La Nouvelle Maison Rustique*, a three-volume quarto of 2500 pages, and many engravings, and which, like the work under discussion, treats of urban matters of every kind.

It will be most convenient to take *La Maison Rustique* and *The COUNTRY FARMER* together, and I shall only refer to the French edition in cases where the sense of the original is lost in the English.

The work is in seven books, of which the three first occupy 630 pages, and the last four 270. The second book is devoted to gardens, but the third, treating of orchards, Vines, &c., is also of interest to horticulturists. It is, of course, impossible to apportion to each writer that part of the work for which he was responsible; but I imagine the first three and perhaps the fourth books may be attributed to Dr. Stevens. The French edition, I ought to have said, is pagged on one side only, the right hand one facing the reader. Like all works on gardening at that early date, Pliny, Dioscorides, and others, were freely copied, but apart from such matter, there remains much that was novel and interesting. It is indeed impossible to read some of the chapters on gardening without coming to the conclusion that it must have exerted a not inconsiderable influence in forming the style of gardening among a people so fond of the pursuit as the English. So early indeed as 1577 *The Gardeners' Labyrinth* contains an engraving of one of the flower-beds portrayed in *La Maison Rustique*; and in Surfleet's as well as that of Markham, all the engravings are reproduced. The work, strange to say, is passed over in silence by many modern writers, as for instance by the author of *In Praise of Gardens*. The situation of the garden was to be towards the north rather than the south of the house, whence it was entered directly. The proprietor, as "Lord of the farm," had a private doorway from his apartments, and from the windows of these he was able to overlook the whole of the ground devoted to flowers, vegetables, herbs, and fruits; whither also the smell of flowers and the humming of bees was conveyed to his senses. There were two chief gardens, and if it could be afforded, these were surrounded by a wall, though a quick-set hedge (*haie vive*) composed of Briars, Whitethorn, and Sloes; or plants of the Spindle-tree mixed with Briars was considered equally good and much cheaper. Dead hedges made of osiers, reeds, and thorns, are condemned as costly on account of requiring

annual renewal, and also because they became inefficient through quickly getting out of repair.

The kitchen garden was divided from the garden of pleasure by means of a walk 18 feet wide, and a hedge planted with wild Apples, Paradise Apples, Gooseberries, "Hasells," Medlars, Eglantine, &c. These were trimmed, and seem to have been formed into a wide wall of vegetation, in which arbours, &c., were formed. The original has "berceaux," "chappelles," and "oratoires." The English work has "contrived into arbours, or as it were into small chappels or oratories," and places to make a speech out of, that many standing about and below may hear, all of the latter part of which Surfleet must have imagined, as it does not occur in the French work. Elms are strongly recommended to be planted for shelter. Inside the kitchen garden-fence, but separated from it by a 3½-foot alley, a lattice-work trellis, over-arching at the top towards the garden, ran the whole length of the latter, and was planted with Vines for the provision of verjuice. Dwarf-growing herbs were planted in lines, one on each side at the base of the trellis, but so as not to interfere with the well-doing of the Vines.

The best kinds of wood for trellis-poles were those of Juniper, and Willows and Broom twigs were employed to tie the shoots to their positions. An alley, corresponding to that already mentioned, extended along the garden-side of this trellis, and right along the other side of this alley was a border devoted to Cucumbers, Melons, Gourds, Pompons, &c. Bacon's proposal of an arched hedge on pillars sounds grander than this, but is not so practical. In the disposal of the rest of the space, Stevens was severely utilitarian. The ground was subdivided into sections, separated by means of 3-foot alleys. Turnips filled one such section, and Coleworts another; and the others were further divided into long beds or "floores," just wide enough to reach across, and weed comfortably from the 2-foot alleys that separated the one from the other; and each was planted or sown with a particular crop.

In addition to vegetables, certain herbs found here a place. These included Sage, Hyssop, Lavender, Rosemarie, &c. "Cammomil" required a section to itself in which to grow plants "for to make seats and a labyrinth." A space set apart for physic herbs is also advised.

Several chapters discuss sowing, planting, weeding, gathering, and preserving crops and seeds; and a discussion of the length of time the latter may be kept without losing their germinating power.

Following this is a number of chapters on particular crops, the first being a lengthy one on Coleworts. Mention is made of the common Colewort, the "Choux cabus," which is called in the English edition "the white or Apple Colewort." Curled and Romaine Coles are also noted, and red Coleworts, about the existence of which the writer seems to have experienced some doubt, because he proceeds to say they are procured by watering with the lees of red wine! The unpractised reader is also warned that seed more than three years old will produce Radishes, and if not Radishes, then he may look for Turnips!

Passing over a lengthy chapter on Lettuces, the one following treats of Endive, Sow-thistle, and Succorie. Sow-thistle (*la laceron* ou *Cicerbita*) had at this time fallen into disrepute except among the Italians. It was, however, still cultivated as a garden crop, but used to feed conies and hares, the fondness of the latter animal for it procuring it the designation of *Palais de Lievre*, or Hare-taste. English names of the Sow-thistle include Hare's-lettuce, Hare's-thistle, Hare-wort, and Herb-wat, wat being an old name for that timid creature, as in *Venus and Adonis*:—

"Poor wat far off upon a hill
Stands on his hinder legs with list'n'g ear,
To hearken if his foes pursue him still."

Concerning wild Succorie (*Cichorée sauvage*), it is stated the plants were covered with sand and earth—a rough-and-ready method of blanching. This plant was also called *Morsus diaboli* and yellow Devil's Bit, from its pramorse root. *Corne-de-Cerf*, or Hart's-horne, is another common weed that has in France long held a place in gardens. It is noted in *La Nouvelle Maison Rustique* as a "salladé" plant. It is *Senebiera Coronopus*, and is a very old garden herb, called in England "Herb Ivy" or "Herb Ive," and is the "Erbe Ive" that growth in our yerd that merry is" of Dame Pertelot. "Triguemadam," called also Trickmadam and Prickmadam, was employed in spring salads, and appears in many early English works on gardening. It is *Sedum reflexum*, in Scotland called "Daunerin' Kate."

Marigolds procure a chapter to themselves. They

were employed in pottage, in salads, and were preserved boiled with sugar, and conserved in a dry condition. *R. P. Brotherton.*

(To be continued.)

PLANT NOTES.

ABUTILON INSIGNE.

GROWN as a climber, this little-known plant is quite effective, and flowers freely. The growths are slender, and need supporting by stakes if grown otherwise, while the pendulous side-growths, about a foot long, which bear the flowers are better seen. A plant planted under the stage, and trained upon the roof in the cool-house here, is now in bloom. These are marked with heavy rich purple lines, interlaced with a few blotches of white ground colour, and are about 1½ inches in diameter. The foliage, which is heart-shaped, is large upon the main stems, and covered by short brown hairs. An open compost of good peat and loam are essential for the cultivation of this New Grenadan species, which was introduced by Linden in 1851. *R. L. Harrow, Royal Botanic Garden, Edinburgh.*

KENNEDYA AND HARDENBERGIA.

What can our cultivators tell us about *Kennedya Marriatæ*, a form of *K. prostrata*, a cool greenhouse climber, with soft velvety foliage? It is an introduction of Baron Carl von Hügel from Australia, and was once much admired. There are others nearly as pretty, but they are fast becoming scarce in gardens. *Hardenbergia monophylla*, named in honour of Baron C. v. Hügel's sister, the Countess Hardenberg, is likewise a greenhouse climber, whose chief season of flowering is the month of April, but which shows a few blossoms in almost every month in the year. The pretty blossoms are axillary, short racemes of a purplish-violet colour. *P. M.*

A FRINGED HOLLYHOCK.

The fringed Hollyhock "*Allegheny*," which is being introduced this year, has very little in common with its parent, the old-style double Hollyhock; and a flower separated from the stock would hardly be recognised as that of a Hollyhock at all, on account of the novel arrangement of the petals, which are deeply fringed or cut, rather transparent, and of a silky texture. The veins throughout the petals give the appearance of crumpled or crushed silk, and this to such a degree that a florist of long experience refused to believe that a flower of the *Allegheny*, which a lady wore pinned on her coat, was real. *American Gardening.*

TREES AND SHRUBS.

VARIETIES OF CEDRUS DEODARA.

Of this beautiful Indian Conifer there have been introduced within recent years several varieties, which will rank as valuable trees for garden decoration, although at the present time they are comparatively unknown. *Cedrus Deodara*, the type, has been figured and described in the pages of the *Gardeners' Chronicle* more than once, and of this we now have *C. D. var. aureo-variegata*, its yellow colour being very marked. In style of growth and foliage it is exactly like the ordinary form, although the young plants exhibit more vigour. It is a sport that appeared, it is said, in a nursery in France a few years ago.

C. D. var. verticillata glauca is an older but beautiful variety that is worthy of more extensive planting. In appearance it affords a marked contrast to the type; the leaves, of a glaucous green colour, are arranged in whorls, and its growth is also more vigorous than that of *Cedrus Deodara*. *E. S., Woking.*

PRUNUS CERASIFERA.

Not one of the *Prunus* family flowers in greater profusion or with greater regularity than this species, commonly known as the Myrobalan. It is generally about the beginning of April that it is in full bloom, and it is then, perhaps, the most beautiful of all trees

and shrubs in flower, the whole tree being one complete mass of white. The flowers are each about three-quarters of an inch in diameter, and they clothe every twig profusely. The tree itself grows to about 20 feet in height, and being of rounded, rather spreading habit, is often wider than it is high. The leaves, which are only just in evidence at the time the tree is in bloom, are ultimately about 2 inches long, and ovate. The native country of the Myrobalan has not been definitely ascertained, but in view of its close relationship to, or more likely its identity with, *P. divaricata*, it is almost certainly from the Caucasian region.

The tree, now widely distributed in gardens, and known as *Prunus Pissardi*, is nothing more than a variety of *P. cerasifera* with reddish-purple foliage. Its proper name is *P. c. var. atropurpurea*. It is a pretty plant, either in flower, in young leaf, or in autumn before the leaves fall. But there is just a possibility that we may come to see too much of it. The overplanting of trees with abnormal characters either in habit or in colour of leaf (but more especially the latter), is a thing to be avoided. *P. cerasifera* is no less beautiful a tree than its coloured variety and (although there is room for both), I should prefer to see it planted the more freely of the two.

PRUNUS SIMONI.

This is one of the latest additions made to the Almond section of the genus *Prunus*, and is at present one of the rarest in gardens. It was, however, described by Carrière, and figured in the *Revue Horticole* as far back as 1872. In the section to which it belongs it is distinct because of its erect mode of growth. In the United States, this fastigate character is so marked as to give the species much the same general aspect as a small Lombardy Poplar. It is now in flower, its blossoms being pure white, and $1\frac{1}{2}$ inch across. The leaves are about the same as those of the common Almond, only broader at the base. There is a specimen in the Kew Arboretum about 7 feet high. Under the bright skies of California this *Prunus* bears its deep red-purple fruits freely, and promises to be of economic value on their account. It is said to be originally from China, but I do not see any mention of it in Mr. Hemsley's *Index Floræ Sinensis*. W. J. B.

FLORISTS' FLOWERS.

THE HOLLYHOCK.

THERE is reason to believe that the disease once so destructive to the stately Hollyhock is less harmful than formerly, and there is a promise that this fine flower may dominate in gardens. Whatever might have been the cause of the outbreak of the disease in the first instance, which proved so destructive to many of the old-named varieties, its ravages have been stayed to a considerable extent by raising seedlings of robust constitution, and, to some extent, disease-proof. If something has been lost in the direction of size and quality of bloom by the destruction of some of the old-named varieties, there is an inducement for raisers to seek to reproduce them by improving upon what remains, and at the same time without loss of constitutional vigour.

When the Hollyhock was at the height of its popularity, excessive propagation had to be resorted to to obtain a supply, and experience teaches that this tends to physical deterioration. We may then look forward hopefully to a new race of Hollyhocks, that shall not be so disfigured by the fungus as were the varieties of a past generation.

A line of Hollyhocks along the fringe of a shrubbery-border suggests one of the most suitable positions for them. They can be dotted here and there, while some who aim at perfecting the flower prefer to have a small plantation where they can readily get among the plants; and this method is all the more desirable in cases where some blooms are grown for exhibition purposes. Classes for cut blooms still find a place in some schedules of prizes, and floricultural societies which had discarded the Hollyhock are found to be placing it among their competitive exhibits once more.

Hollyhocks should have good cultivation, as it is sometimes found that well-grown plants offer greater

resistance to the progress of the disease than do those less generously treated. The plants flourish in a good garden soil, trenched to the depth of 2 feet, with plenty of thoroughly decomposed manure mixed in with it. They will stand a strong manure; even night-soil has been employed—as a matter of course mixed with garden soil. The plants do well in a wet subsoil during summer, but in the winter, with such a condition of moisture, losses occur. Two measures have been resorted to to carry old stools of fine varieties safely through the winter. One is to lift the roots, place them in large pots, and winter them in a cold frame, but this can be done only in the case of a select and limited collection; or to secure the safety of certain varieties, an old method adopted by the late Mr. William Chater was to draw the soil away from the old stools, and fill in with some porous material, such as coarse sand, through which water would rapidly pass.

It is always best, in the case of seedlings from a fine strain obtained from seeds sown in April or May, to put them in fair-sized pots in October, wintering them in a cold frame, and planting out in April. If seeds be sown in warmth early in March, and grown on strong enough to put out in May, they will flower the same season, which is a decided gain in point of size.

The liking of the Hollyhock for water during summer is great. It is gross feeding and plentiful watering which produce large and handsome blossoms; liquid-manure or dressings of guano are very helpful; in applying these it is well not to place or pour them too near the stem, but to take care that they can find their way down to the roots, and give them that support they need. R. D.

THE WEEK'S WORK.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

The Peach house.—After the fruit is stoned, the warmth may range from 60° to 65° by night, 70° on sunless days, and 80° to 85° with bright sunshine beyond this; and when closed, and the trees are syringed, it may rise to 90° without injurious effects. The most should be made of the hours of sunshine, and ventilation should be abundant or stinted in accordance with the state of the weather. By allowing warmth in the hotwater-pipes to rise at an early hour in the morning, a temperature of 70° may be attained by 9 A.M., or earlier; and then on mild days it will be possible to afford some amount of air at that time, or soon afterwards. As the sunheat increases, the pipes should be allowed to cool till closing-time, when an increase may again take place. Be careful to avoid the aridity caused by highly-heated hotwater-pipes, and a higher night temperature than that given above. Let the trees be syringed with tepid water twice a day, and damp down as well if the air of the house feels dry. There must be no lack of moisture at the roots; all the same, the practice of affording dribbles and keeping the borders saturated should be avoided, but wait till the soil actually wants water, then afford it copiously. If the border is an old one, and the soil poor light loam, manure-water may be occasionally afforded during the final swelling of the fruit. As colouring begins to take place, put aside or remove wholly or in part those leaves that shade the fruit from the sun. Let the shoots be secured to the trellis at short intervals of time, and endeavour to bring this kind of work to an end before the fruit ripens, so as not to have to carry it on whilst the latter is on the trees. When colouring begins, afford more air and less water to the soil, and stop the syringing of the trees. After stoning, the final thinning should be done, healthy vigorous trees may be allowed to carry one fruit for every 9 inches square for middle-sized varieties, and 1 foot square for large ones. Weak or very aged trees should not carry so many fruits. Nectarines may be left at one fruit for every 9 inches square, unless weak or aged. Whilst Peaches are stoning, a warmth of 5° less will suffice than that given above. Former directions as to disbudding, training, &c., should be carried out.

Late Houses.—When the leaves begin to expand, disbudding must receive attention as in the case of the early forced trees. Some varieties set their fruits at this season very freely, and even those which do not usually fruit abundantly; and in cases where two fruits set at about one point the smaller should be removed, as well as all fruits found between or behind the shoots. When of about the size of a Hazel-nut, thin them down to about twice the number that will at last be

left to ripen, going over the trees several times at intervals of a week, and thin out the smallest and worst placed. The degree of warmth to be maintained after setting will depend upon the date at which fruit is required, that is, whether it is to come on in the ordinary course, or it is desired to retard them by free ventilation, but still without unduly checking progress.

Peach and Nectarine trees in Pots.—The usual shape of these trees is somewhat columnar, and disbudding will require to be carefully done, the method being much the same as that adopted for fan-shaped wall trees. On each side branch near to the base, one young shoot or even two may be left, and one beyond the fruit. Some of the superfluous shoots may be taken off, and some left to be taken off a few days later. Where there is fruit and a young shoot from the same joint, pinch out the point from the shoot when it is an inch long. The number of young shoots to be left at the base of the leader depends on the increase of height required, and further on, one should be left as a leader. The trees should stand on a cool moist bottom, and the application of water at the root must be carefully guarded against, giving them an examination every day, and in very hot weather twice. In other respects the treatment of the Peach and Nectarine in pots, is the same as for plants in borders.

HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Strawberry Beds.—Hoe the beds through during dry weather, for the purpose of destroying small weeds, so that the land may be thoroughly cleaned before it is time to put on a mulch. Such perennial weeds as Couch-grass, Docks, Dandelions, &c., should be removed by extracting the roots before they have time to establish themselves; at the same time, care must be exercised not to injure the roots of the Strawberries, which are more than usually susceptible to injury by root disturbance. When Strawberry plants have become established in the beds all the cultivating that is required may be done with the hoe and rake. Owing to dry weather and the absence of frost, the manure that was put on as a top-dressing during the autumn has not decayed, and will need to be stirred about with the rake until it is broken up. To obtain extra strong runners for early planting, a number of strong and healthy plants should be reserved exclusively for this purpose, and the flower-stems pinched off as soon as they can be seen, which will cause the whole of the plant's strength to be diverted to the production of runners.

Peach and Nectarine trees have made little progress in the Midlands during the recent cold weather, but attention to the means of protection previously advised has preserved the flowers from injury, and the fruits have set well. In warmer districts the trees are probably ready to be again disbudded, and all shoots necessary to be retained for the building up or extension of the tree will have now to be selected. It is well to leave two of the best placed at the base of each branch until one of them gets a good lead, and can be tied in; and let these spring from the upper sides of the branches nearest to the centre of the tree. If the trees are trained on this principle they will be the more uniform in growth, cover the walls better, and be much easier to regulate should a branch die. The remaining shoots on the branches should be further reduced to 3 inches apart for the present, preserving at the same time all the best-placed and strongest fruits. The work of disbudding requires much judgment, for if too many buds be removed at one time, a check will result, and many of the fruits will turn yellow and fall off. Let means be taken to prevent aphides from increasing among the young leaves, or much damage will be done. Tobacco-powder is the safest remedy, and may be effectually applied when the foliage has been previously sprayed by means of a syringe.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Liliums.—The early batch of *L. longiflorum* var. *Harrisii* being now at the point of flowering, should be removed to the intermediate-house for three or four days before taking the plants to the cool conservatory or greenhouse; the stamens should be cut off at the earliest opportunity, and before the pollen has fallen on the petals and spoilt their purity. To remove the stamens, moreover, prolongs the life of a blossom. Some more bulbs may be placed in heat, in order to keep up the succession, should the late potted bulbs not be sufficiently forward. *L. auratum*, and *L. spe-*

cosum, which were potted early will now be growing, and in need therefore of a light position to prevent etiolation. They should be stood on coal ashes, and afforded water very carefully, and plenty of air in fine weather. Lilies for late-flowering may still be potted, placing them behind a north wall or similar cool spot, covering the pots with moss, or inverting other pots over them till such time as growth commences.

Gladiolus.—The early-flowering varieties, or those that were potted early, may be gently forced into flower. The *Gladiolus* will not stand much forcing, the flower buds turning yellow and dropping off if it be attempted. The general stock should be grown on steadily for the present in a cool house or pit.

Iris sibirica, when grown in pots, is valuable for supplying flowers for cutting, for filling vases, &c., and for dinner-table decoration. It cannot be forced, and cool treatment must be afforded always, potting the bulbs early in the autumn, and growing them on steadily throughout the winter, a kind of treatment that brings the plants into flower three weeks or a month before those out of doors.

Genistas (Cytisus).—Any of these plants that are about to go out of flower, may have all the weak shoots removed, and the chief ones shortened sufficiently to make shapely plants, and those plants which are in need of more rooting space may be repotted forthwith. To start the plants into growth, place them in an intermediate-house, and syringe them daily. If infested with scale, let the plants be cleansed before growth ensues. Do not crowd the plants together, but afford them full light or they will not flower satisfactorily. Cuttings should now be made and put in, selecting for this purpose shoots that have no flowers and have not flowered, and insert these to the number of five or six round the rim in pots filled with light sandy soil and coated with fine clean sand. Strike the cuttings in moderate heat; some few plants should be raised every year, and those that have been cut back for two or three years thrown away.

Abutilons placed against walls or pillars in conservatories should be pruned hard, as by doing this and judiciously thinning the weaker shoots when growing ensures a lengthened period of flowering. When planted in severely restricted borders, a portion of the surface soil should be removed annually and replaced with rich pasture-loam and decayed manure. Cuttings of the dwarf, free-flowering varieties may be struck in heat at this season, and those which were struck some time ago may be put into the pots in which they are to flower.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Dendrobiums have formed a prominent feature in the houses for several months past. Owing to the ease wherewith the majority of them may be cultivated, and the large number of distinct varieties now obtainable, no group of Orchids is more valuable to the amateur than this one. Little space is sufficient to accommodate them, and when well grown the plants produce an abundance of blossoms of great value for decorative purposes. The following very select sorts are worthy of every attention:—*D. Wardianum*, *D. crassinode*, *D. Findleyanum*, *D. Falconerigiganteum*, *D. albo-sanguineum*, *D. crepidatum*, *D. cretaceum*, *D. primulinum*, *D. tortile*, *D. superbum*, *D. lituiflorum*, the numerous forms of *D. nobile*, and the following hybrids: *D. micans*, *D. Clio*, *D. Enterpe*, *D. Venus*, *D. Dominii*, *D. endocharis*, *D. Sybil*, *D. Apollo grandiflorum*, *D. melanodiscus*, *D. Juno*, *D. Burfordiense*, *D. Wiganæ*, *D. euosmum leucopterum*, *D. e. virginale*, *D. Aspasia*, *D. Rainbow*, *D. Cordelia*, *D. Ainsworthi*, and all its congeneric crosses, of which may be mentioned *D. splendidissimum grandiflorum*, and the new Woodhatch variety. The majority of these plants having now flowered, are making new growths, which when only a few inches high, emit roots that delight to run into fresh compost, and no time must be lost in satisfying this requirement. Plants that have already sufficient root-space, and are in a strong, healthy condition, will need only to be re-surfaced. Before commencing this work, allow the old material to become dry, as it can be more easily removed when in that condition, then pick out as much of it as possible, even to the crocks, and if necessary the drainage may be improved. In all such operations the greatest care is necessary to prevent injury to the roots. Let the compost consist of equal parts peat and sphagnum-moss, with a free addition of clean crocks. In most collections there will be some plants that have deteriorated

and such should be turned out of their pots, and all decayed roots cut away, afterwards cleansing the remaining ones in tepid rain-water. It will be best to put such plants into very small pots, affording plenty of drainage, and using sphagnum-moss only for them to root into. In the case of established plants, remove no more of the old material than is really necessary, and thus avoid unnecessary root-disturbance. At Burford we carefully break the old pot, and take away as much of it as is practicable; and if the drainage be encircled with living roots, it is not disturbed, but a little of the old compost on the surface is removed, and that around the sides carefully loosened. The plant is then placed into a pot one size larger, which is filled up with clean crocks to within an inch of the rim. The new compost is then made moderately firm around the plants. For a few weeks succeeding such work keep the plants rather on the dry side, and as the young growths lengthen and send forth roots, the amount of water given may be gradually increased. Prevent water lodging in the young growths, as they are liable to rot from this cause. Sponge the under-sides of the leaves often enough to keep them free from red-spider and Thrips. When the plants are thoroughly re-established, and the roots are clinging around the sides of the pots, the foliage may be finely sprayed with tepid rain-water at closing-time on warm, sunny afternoons. All the *Dendrobiums* mentioned require a hot, moist atmosphere, and an abundance of light. The Australian *D. superbiens* will now be starting into growth, and will also require to be repotted. Such strong erect-growing plants as *D. nobile*, *D. Linawianum*, *D. Dominii*, *D. Burfordiense*, and the *melanodiscus* and *chrysodiscus* crosses grow well enough in ordinary flower-pots, while those with pendulous stems should be given shallow hanging-pans with perforations around their sides. I use these pans in preference to teak baskets, because the plants are more readily managed when they require a shift. Propagation of the *Dendrobiums* already enumerated may be effected by taking off any of the pseudo-bulbs which have not flowered, cutting them up in lengths, and laying them on sphagnum-moss in a hot propagating-case. Where no such convenience exists, the troughs on the hotwater-pipes may be made use of by half filling them with damp sphagnum-moss, and placing over them pieces of glass to prevent evaporation. After a few weeks young shoots will appear upon the stems, and immediately they commence to emit roots they should be severed and potted in sphagnum-moss only, and afterwards given the same kind of treatment as older specimens. The present is a suitable time to pot off young seedling *Dendrobiums*. They grow vigorously when potted in sphagnum-moss, well mixed with small crocks; but when they arrive at the flowering stage, fibrous peat should be added to the moss.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Sowing Grass Seeds.—The present is a very suitable time for sowing seeds of lawn grasses, and for renovating old lawns by turfing or sowing. In the formation of a new lawn, level the ground evenly in the first place, then rake it well, and afterwards afford it a good rolling, and finally go over every bit of it to make sure it is perfectly level, making up all uneven places firmly, employing for this purpose loamy soil. When this is done, the ground will be ready for the seed; and now comes the most important factor, viz., good seed. Never sow seed which has been obtained from mangers and cow-cribs, as in all probability there will be many weed-seeds and unsuitable species of grasses. Rather procure seed from a nurseryman of repute, and have mixed with it Clovers of low growth, namely, *Trifolium repens* or *T. minus*. Some cultivators sow Clover separately, and hack it in before sowing the grasses. Lawn mixtures may be sown at the rate of 50 lbs. to the acre, and it is always better to sow too thickly than too thinly. [In order to make sure that the grasses are of the right species and in the desired proportions, the following formula, which may be accepted as being of utility in average soils, is given in the *Gardeners' Assistant*, p. 692, as being the quantities required for sowing an acre:—*Lolium perenne tenue* (Rye-grass), 20 lb.; *Cynosurus cristatus*, 5 lb.; *Festuca duriuscula*, 3 lb.; *F. ovina tenuifolia*, 2 lb.; *Poa nemoralis*, 2 lb.; *P. semper-virens*, 2 lb.; *P. trivialis*, 2 lb.; *Trisetum flavescens*, 1 lb.; *Trifolium repens*, 6 lb.; *T. minus*, 2 lb.; total, 45 lb. Ed.] Choose a fine, still day, and distribute the seed evenly over the surface of the ground, hack and rake it in with a wooden rake having

close-set teeth, and afford the ground a thorough rolling. If the weather is favourable to seed-germination, in about two months from sowing the whole will have become green. The roller should then be passed over it again, in order to make the soil firm about the roots of the grasses, &c. Do not allow any one to tread on the land, and take care to scare away the seed-eating birds. For the first year, the scythe only should be used in cutting the grass, and during the heat of summer, once a fortnight will be often enough to mow. The roller should be passed over a new lawn before each mowing. In very dry weather, applications of water may be necessary if the soil is of a light character. It is the usual practice to place strips of fine green turf, 6 inches wide, round the margin of a lawn that is to be sown, the edges of dug ground being of too loose a nature to afford the necessary protection to walks and beds. If an old lawn is overrun with moss, the latter should be scratched off with iron rakes having sharp teeth, and the land slightly loosened with a digging-fork, and some good loam spread over the bared parts, and beaten down hard with the spade, or rolled. Grass-seeds and Clovers being then sown, and raked in, and again beaten with the spade. Under trees and in shady places, where the grass habitually dies, the ground should be slightly loosened, and some finely-sifted loamy soil spread over it, and be sown as in the former case, not rolling it very much. The drip from the trees makes the ground uncommonly hard, and difficult for the grasses to establish themselves, and special mixtures of grasses should be employed for sowing shady lawns and the land under trees. Old lawns, if not in a very bad state, may be renovated by means of special artificial manures, or by spreading wood-ashes, sifted loam, leaf-mould, and decayed stable-manure; light land being afforded stiff loamy soil, and heavy land soil that is rather lighter. Fish-manure has a lasting and beneficial effect on lawns, but it has an objectionable odour for some time after use. Lime has a good effect on soil having an excess of humus; and nitrate of soda is good for soils deficient in nitrogen, but this substance has a better effect when afforded in conjunction with farmyard-manure, the latter being laid on the lawn in the winter and the nitrate in spring and early summer.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Large Onions.—Onions that have been pricked out into frames and boxes should be given as much air as possible during mild weather, and thus be slowly hardened-off before transplanting them into the open garden. When this is about to be done, choose a piece of land that has been deeply dug and well manured, and prepare the surface of the ground as in the case of sowing spring Onions. Put the plants out in rows 16 inches apart, allowing 9 inches between each plant. A mild showery day is most suitable for the work.

Beetroot.—To prevent the roots from becoming forked or otherwise ill-shapen, the ground for this crop should be trenched not manured, and be thoroughly well worked with the digging-fork. Sow the seed thinly in drills 12 inches apart and 1 inch deep. Varieties that produce even-sized roots of good colour are Blood-red, Pineapple, Cheltenham Green Top, and Pragnell's Exhibition.

Broccoli for the Main Crop.—Seeds should now be sown in drills half an inch deep, and 9 inches apart, on a warm, open border. Label each variety to prevent mistakes, and protect the seeds from the birds. To provide a regular supply I have found the following sorts excellent:—For autumn and early winter, Veitch's Self-protecting and Michaelmas White; for winter supply, Sutton's Superb Early White and Snow's Winter White; for spring use, Veitch's Maincrop, Leamington, Sutton's Snow White, and Knight's Protecting; for late spring and early summer use, Veitch's Model, Sutton's Continuity, Late Queen, and Methven's June. Make another sowing towards the end of this month of seeds of the Early and Late Purple-sprouting Broccoli.

Brussels Sprouts.—Make another sowing of Sprouts on the open border. Plants that have been raised under glass should be pricked out into rows 6 inches apart on a sheltered border. Occasional waterings in dry weather will do much to strengthen the young plants.

Curled Kale.—Sow seeds of Exquisite Curled, Dwarf Late Curled, and Cottager's Kale, in drills or beds, proceeding the same as when raising Cauliflowers or Cabbages.

Celery.—Make another sowing of seeds for a successional crop, as recommended on p. 182.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, APRIL 16 { Ghent Quinquennial Horticultural Exhibition (open until 24th inst.).

WEDNESDAY, APRIL 20 { York Florists' Spring Exhibition.
Durham, Northumberland, and
Newcastle Horticultural Society's
Spring Exhibition (2 days).

THURSDAY, APRIL 21—Linnean Society Meeting.

SALES.

TUESDAY, APRIL 19 { Roses, Greenhouse Plants, Hardy
Perennials, &c., at Protheroe
& Morris' Rooms.

WEDNESDAY, APRIL 20 { Japanese Lilies, Roses, Tube-
roses, Palms, &c., at Protheroe
& Morris' Rooms.
Border Plants, Lilliums, Bulbs,
Palms, &c., at Stevens' Rooms.

FRIDAY, APRIL 22 { Imported and Established Or-
chids, at Protheroe & Morris'
Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—48° 8°.

ACTUAL TEMPERATURES:—

LONDON.—April 13 (6 P.M.): Max., 58°; Min., 44°.

PROVINCES.—April 13 (6 P.M.): Max., 54°, York; Min., 43°, Shetland.

Soudanese
Cereal.

M. DYBOWSKI contributed a paper on this subject to the Academy of Sciences, from which we take the following particulars:—The natives of the Soudan have not, hitherto, included cultivated European cereals in their diet. These are replaced by Maize, Sorghum, and mountain Rice. To these cereals, the use of which has long been known, must be added another, in wide-spread use. It is a plant with slender branches, thin ears, and producing a grain much in request with the Soudanese, to whom it furnishes an important proportion of their regular fare.

This cereal is known, botanically, as *Digitaria longiflora* of Persoon, or *Paspalum longiflorum*, Retz.

It grows wild in all the tropical and sub-tropical regions of the old world, where it sometimes covers vast plains. But it is nowhere used as food save in the western Soudan. Capt. BINGER, in the account of his remarkable journey, says that it is included in the diet of the natives of the central Soudan.

In French Guinea, in Fouta-Djalou, where it is known under the native name of *foundounié*, it is systematically cultivated.

The cultivated plant differs from the wild type in having thicker and more ovoid seeds; it is also entirely glabrous, while in the wild state it is hispid. Further, the glumes do not adhere firmly, and the seed can be ground very easily.

In French Guinea the method of cultivation is to scatter the seed on the soil after freeing it from the "brush" by burning. In three months the plant develops and bears seed. These are easily separated by threshing. They are ground by pounding them in a wooden

mortar. The semolina thus obtained constitutes a fare of high nutritive value.

Chemical analysis shows that the composition of these seeds closely resembles that of Rice, though distinguished by a greater proportion of fatty matters, which are found in an appreciable quantity, equal to that discoverable in Millet.

CHEMICAL COMPOSITION OF SEEDS OF PASPALUM LONGIFLORUM COMPARED WITH OTHER CEREALS.

	Buck- wheat.	Rice.	Maize.	Barley.	Rye.	Wheat.	Millet.	Pas- palum.	Components.
	11.93	13.11	13.12	13.77	15.06	13.65	11.66	9.20	Water
	10.30	7.85	9.85	11.14	11.52	12.35	9.25	7.67	Protein
	2.81	0.88	4.62	2.16	1.79	1.75	3.50	5.34	Fatty matters
	55.81	76.52	68.41	66.93	67.81	67.91	65.95	77.33	Starch and dextrine
	16.43	0.63	2.49	3.31	2.01	2.53	7.29	2.56	Woody matter
	2.72	1.01	1.51	2.69	1.81	1.81	2.35	3.90	—

The bran is proportionately but little abundant. It represents 9.75 per 100 of the weight of the seed. Microscopical examination shows that starch-grains of *Paspalum longiflorum* have a great analogy to those of Maize, from which, however, they are easily distinguished by their smaller size, as they never measure more than 19 thousandths of a millimetre. All the starch-grains have an appreciable uniform bulk, and few are met with measuring less than 12 thousandths of a millimetre. The form of the hilum also presents a quite distinct visible character; it is, in fact, broad and wrinkled. Owing to its nutritive qualities and the facility with which it can be cultivated, this grass deserves to be reckoned among the most useful cereals; it is perhaps worth while to encourage the growth of it in the colonies.

The Mildews of
Cereals.

AN interesting paper by M. JAKOB ERIKSSON has just appeared in the *Revue Générale de Botanique*, February, 1893, p. 33, entitled "Principaux résultats des recherches sur la rouille des céréales exécutées en Suède." An English version may be found in the *Botanical Gazette* (Chicago), January. The author gives a table showing that in 1890 only three species of Puccinia were known, viz., (1) *P. graminis*, (*Æcidium Berberidis*); (2) *P. rubigovera*, (*Æc. Asperifolii*); (3) *P. coronata*, Corda (*Æc. Rhamni*); and one variety of the second, simplex. The first had been found on the four cereals, Wheat, Rye, Oat, and Barley; the second on Wheat and Rye; the third on the Oat, while the variety simplex occurs on Barley.

The first species has been subdivided into two, viz., *P. graminis* (black mildew), and *P. Phlei-pratensis* (no *Æcidium*); simplex has

been raised to a species, and three new ones have been discovered; *P. glumarum* (a yellow mildew, no *Æcidium*); *P. dispersa* (a brown mildew, *Æc. Anchusæ*), and *P. coronifera*, (*Æcidium Rhamni Cathartice*).

Of these species *P. graminis*, which is known to attack above a hundred different species of grass, has six distinctly "specialised" forms; and the remarkable discovery about them is, that certain of these "forms" present no morphological differences whatever, neither externally nor microscopically. One cannot distinguish them either by size, colour, or distribution of the pustules, nor by size or structure of the spores. Nevertheless, there are real differences in their natures, inasmuch as each "form" of the same species is invariably linked with the special kind of cereal it attacks. Hence, though the author uses the word "form," he applies the word "specialised." A rare exception occurs, in that one of the black mildews can attack both Barley and Rye.

Including all the wild grasses attacked, there are thirty different forms of mildew, which are correlated with the seven different species of the genus Puccinia. Hence, a much greater restriction exists than was thought to be the case, in indiscriminate propagation of *P. graminis* among various members of the grasses. Omitting exceptions, there are eight forms of mildew which attack cereals, and eleven other forms are absolutely localised upon single species of grasses respectively. Hence, one cannot regard wild grasses as furnishing a source of contamination to cereals.

A question might arise whether one and the same *Æcidium berberidis* could supply all the forms of *P. graminis*. Experiments have demonstrated the contrary, for the form of *Æcidium* which produces the black mildew of the Oat can only communicate it to the Oat, similarly for the Rye, Barley, &c. Hence, such is an additional restriction to indiscriminate contamination.

The first form of *P. graminis*, called *Secalis*, can attack Rye, Barley, three wild species of Triticum, Elymus and Bromus; now *T. repens* is more abundantly attacked than all the other grasses in central and southern Sweden; but still Barley and Rye, when growing close by, are but slightly touched. Experiments corroborate this, for Barley sown side by side with badly-affected Couch-grass remained unaffected. It is well known that different varieties of cereals have different resisting powers, and even separate clumps of the same species of grass vary in this respect. The general conclusion, therefore, is, that the spread of the mildew from plant to plant is often very slight, whether it be between different species, which can be affected by the same form of fungus, or between the *æcidio*- and the *uredo*- and the *teleuto*-spore-bearing plants; or, again, between different sorts of one and the same species of cereal, or between different plants of the one and the same species of wild grass.

The next point observed was the remarkably feeble and capricious powers of germination possessed by the mildew. The author mentions the fact, that the ancient Romans remarked that an alternation of cold nights and hot days is favourable to the development of mildew. M. ERIKSSON has taken this from PLINY, who thus writes:—"Mildew attacks corn most frequently in localities exposed to dews and in valleys, which have not a thorough draught for wind: windy elevated spots are totally exempt from it (*Nat. Hist.*, Bk. xviii., c. 44). In the 68th chapter, he adds:—"Most writers say it is

FIG. 85.—A VIEW IN MR. ARDERNE'S GARDEN, CAPE TOWN : *EUCALYPTUS GLOBULUS* IN THE FOREGROUND. (SEE P. 233)

dew, scorched by a burning sun, which is the cause of mildew; but incorrectly in my opinion, which is, that all blights are caused by cold;" but as he goes on to attribute it to the moon at night, we need not follow him further! Our author now proceeds to say that the difficulty or capriciousness in the germination, partly accounts for the feeble propagation, but not altogether; for even with these kinds, the spores of which propagate easily, the spread of the disease is limited. With regard to the distances, it was previously thought that spores could travel very far, even 300 miles in the regions of the Himalayas; but in 1875, M. J. KÜHN came to the conclusion that 100 mètres distance would prevent contamination between the Barbery blight and Wheat. The author made many experiments, and found that 10 to 25 mètres even, was the greatest distance for infection. Hence he concludes:—"The propagation of mildew depends upon the distance between the plants affected, and those which are healthy. This distance is never considerable."

With regard to the conditions of germination, he found that teleutospores could only germinate when they had been exposed to the air and natural states of cold, to snow or rain, &c. Hence, affected chaff mixed with grain in the barn affords but little fear of propagation of the disease; moreover, teleutospores of the previous year are the only ones which can germinate in spring.

Besides the preceding negations, it remained to discover the positive cause or source of the transmission of the disease. Two observations led the author to a subsequent discovery of great interest. He noticed (1) that the yellow mildew, *P. glumarum*, appeared regularly and in abundance upon certain varieties of Wheat and Barley, four or five weeks after sowing; (2) that the intensity of the disease was more particularly noticeable in the more sunny parts of the field than in the shady places. He then proved by experiments, excluding all chances of external contamination, that the yellow mildew appeared after six to eight weeks, notwithstanding. Hence the disease was in the grain itself, transmitted from the mother-plant. The author discovered how the germs of the disease existed in the grain; he thus writes: "In the immediate neighbourhood of the first spots of yellow mildew the chlorophyll-cells enclose special plasmatic corpuscles, of an oblong form, more often slightly curved, solitary, or united within each cell." "I am led to regard these plasmatic corpuscles, floating freely in the cell, as being the primordial form under which the plasma of the fungus exists. It is a 'myco-plasmatic' state within the protoplasm of the host-plant, and mixed with it, constituting a sort of symbiosis. At a certain moment, and under the influence of external agencies, the two beings thus intimately blended, separate. One sees first some corpuscles of a definite form appear, then a mycelium; and lastly, the spores are not slow to follow."

Hence, the origin of the mildew in cereals can proceed either from an internal germ of the disease in the grain of the cereal itself, or it can arise by contamination from highly-infected plants. The intensity of the disease depends first, upon the energy with which external circumstances (weather, soil, manure, &c.) are capable of developing the fungus from the myco-plasmatic state to that of a mycelium; and secondly, from the intervention of new contagious matter from without.

A VIEW IN MR. ARDERNE'S GARDEN, CAPE TOWN (*Supplementary Illustration*).—We have during recent years afforded our readers several views taken in Mr. ARDERNE'S charming, unconventional garden. These views will have served to indicate a style of planting and of arrangement of trees, shrubs, and herbaceous perennial plants that is rich in pleasing effects, and as far removed as possible from the still too prevalent formality of gardens at home. Certainly, it is only in the warmer parts of England, Ireland, and South-western Scotland that we can with safety plant *Eucalyptus globulus*—the noble tree in the foreground of our illustration—or other species in the open air; but we possess many hardier species of trees as noble in port, and quite as distinct and telling in appearance; and much of the decorative vegetation of low growth observed in the view is available in gardens almost everywhere in these islands, with or without protection in the winter. Our illustration shows a part of the garden adjacent to Mr. ARDERNE'S house, the upper story of which is seen in the middle distance. The scene was photographed by Mr. A. JARMAN, of Claremont, Cape Colony.

BOTANICAL MAGAZINE.—The April number contains descriptions and coloured plates relating to the following plants:—

Allium Schuberti, Zuccarini, t. 7587.—The spreading leaves of this extraordinary species are 1 foot long by 2 inches in breadth; the numerous flowers are borne in simple umbels placed at the top of a scape, the pedicels from 2 to 10 inches in length; the spreading perianth is $\frac{3}{4}$ inch across, 6-parted, and of a pale red colour. Native of Western Asia. Kew.

Myosotis dissitiflora var. *Dyeræ*, t. 7589.—The original *M. dissitiflora* was described in our columns by Mr. BAKER, in 1868, vol. i., p. 599. The present figure represents a variety with taller stature and larger flowers than the average, and which has been dedicated to Mrs. DYER, to whom the Royal Gardens at Kew are indebted for many rare and interesting plants collected in Switzerland.

Crocus Malgi, Visiani, t. 7590.—A white-flowered species with a golden-yellow throat. Native of Dalmatia.

Rhacoma Ribes, Linnæus, t. 7591.—An Armenian species, remarkable for its puckered leaves and handsome panicles of red-winged fruits.

EARLIER OPENING OF KEW GARDENS.—In the House of Commons on the 4th inst., Mr. YOXALL asked the First Commissioner of Works if he could now arrange for the Royal Gardens at Kew to be opened to the public at an earlier hour than noon, and on what date the grounds surrounding the QUEEN'S Cottage were to be formally added to the Kew Gardens? Mr. AKERS-DOUGLAS said he had decided to admit the public to Kew Gardens, not including the plant-houses, at an earlier hour than noon on week-days in the ensuing months of June, July, August, and September. He should be in a better position later on to judge of the extent of the demand by the public for this earlier opening. There were details involved in this proposal into which he was having an enquiry made, and he hoped to give further information in a few weeks' time. He hoped that the QUEEN'S Cottage-grounds might be formally added to the grounds about June 1, but he could not absolutely bind himself to the date. Mr. YOXALL: "Can the right hon. gentleman state at what hour in the morning the gardens will be opened?" Mr. AKERS-DOUGLAS: "That is really a question with which the committee now sitting is dealing, and perhaps the hon. member will allow me to answer this question in a few weeks' time, when I will give fuller details." With reference to the earlier opening of the Gardens, it must be remembered that admission is already freely granted on application to gardeners and students. The demand now made comes from what we may term the local nursemaid element, already well provided for in the neighbourhood. If they can be admitted without interfering with the legitimate work of the garden, well and good; if not, their claims are the last to be considered.

ROSE SHOW FIXTURES IN 1898.—The following fixtures have been made since the list appeared in our issue for March 19:—July 5 (Tuesday), Hereford; July 6 (Wednesday), Tunbridge Wells; July 7 (Thursday), Woodbridge; July 9 (Saturday), Manchester; July 13 (Wednesday), Ipswich; July 21 (Thursday), Sidcup. The next list of fixtures will appear early next month. In the meantime, Mr. EDWARD MAWLEY, Rosebank, Berkhamsted, Herts, will be glad to receive the dates of any Rose-shows, or other horticultural exhibitions where Roses form a leading feature, for insertion in that list.

SPRAYING TO PREVENT THE GOOSEBERRY-MILDEW.—Mr. C. P. CLOSE, of the New York Agricultural Experiment Station, publishes the following summary of his experiments:—"For ten years this station has advocated potassium sulphide as the best remedy for Gooseberry-mildew. In the season of 1897, potassium sulphide, Bordeaux Mixture, lysol, and formalin were tested side by side. The plantation was divided into six sections. In two of these the spraying was begun very early, just as buds were breaking; in two others eleven days later; and in the remaining two sections twelve days after the preceding two sections. The first mildew appeared May 26. By June 7 portions of the plantation were badly mildewed. At this date the lysol and formalin seemed to have done no good. Bordeaux Mixture was more effective, but not so good as potassium sulphide where the treatments were begun very early and medium early. All of the fruit was picked July 6 and 7 so as to market it green. Bushes sprayed very early with potassium sulphide at the rate of 1 oz. to 3 gallons of water gave only 5 per cent. of mildewed fruit; those sprayed very early with it at the rate of 1 oz. to 2 gallons of water gave 6.6 per cent. Bushes sprayed very early with lysol, 1 oz. to 1 gallon of water, gave 24.5 per cent., and those sprayed very early with Bordeaux Mixture gave 37.4 per cent. of mildewed fruit, while the untreated bushes gave 57.7 per cent. to 78.7 per cent. The foliage was not injured by any of the fungicides. At 18 cents per pound for potassium sulphide, the cost of the solution which gave the best results is about one-fifth of one cent per bush for the seven sprayings. The station recommends potassium sulphide, 1 oz. to 3 gallons, or 1 oz. to 2 gallons of water, as the most effective fungicide for Gooseberry-mildew. As a rule, only the English varieties and their seedlings are attacked by mildew, although the American varieties are not always exempt."

THE SOVRAN LETTER-CARDS.—The Sovran Card Co., of King Street, Covent Garden, have recently brought out some new varieties of letter-cards. These novelties are of four forms or patterns—A., which is intended for all communications admitted at the halfpenny rate of postage; B., for closed correspondence at a penny postage, with a reply-card attached; C., similar to B., but including two reply-cards; and D., like C., but intended for transmission at a halfpenny. Patterns A. and D. have an ingenious contrivance for closing by means of tongues of card fitting into corresponding slots; the penny postage patterns close with gum. These letter-cards are ingenious, and especially suitable for business correspondence, whether written or printed (circulars, for instance), as they are quicker to fold and close than note-paper and an envelope. The prices are extremely moderate.

"THE COUNTRY GENTLEMEN'S CATALOGUE."—Published by EDEN FISHER & Co., of Clement's Lane, Lombard Street, E.C., is a publication likely to be very useful in the study of the squire or in the estate office. A full index greatly adds to the utility of the work, which is devoted to the enumeration of requisites for the house, field, garden, &c. At p. 65, in the last paragraph, on the "Future of Wheat-growing," there is an ambiguity, owing, we suppose, to some accident in the printing-office.

MONUMENT TO JEAN LINDEN.—It is proposed to erect, probably at Brussels, a monument to the memory of the botanical traveller who enriched our gardens with so many choice plants. The President

of the committee is Comte KERCHOVE DE DENTERGHEM; the treasurer, M. KEGELJAN of Namur; and the Secretary, M. LUBBERS, the Curator of the Brussels Botanic Garden.

PALMS OF MATTOGROSSO.—The Director of the Botanic Garden at Rio Janeiro, Senr. J. BARBOSA RODRIGUES, has lately published a monograph of the Palms of this district, accompanied by twenty-seven lithographic illustrations. The species and varieties number nearly sixty. Among other things, we note a synopsis of the species of *Cocos* native to Brazil, and therein, under the section *Glaziova*, is included the *Cocos Weddelliana*, Wendland, which has been the subject of enquiry lately. This Palm is stated to be known at Rio by the vernacular name of *Iká*.

A BRANCH OF THE NATIONAL CACTUS SOCIETY.—A society is being formed to be called the Bath and West of England Cactus Society, affiliated with the National Cactus Society. The secretary is Mr. O. G. McLAREN, Oldfield Road, Bath. A show of Cacti in bloom will be held in connection with the Bath Flower Show on June 23.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We desire to draw special attention to the letter of Mr. INGRAM, in our last issue, relating to the Victorian Era Fund. It will be remembered that some dissatisfaction was expressed at the result of the ballot, according to which a non-subscriber came out at the head of the poll. By the agency of the Victorian Era Fund, the unsuccessful candidates at any election, and who have been subscribers in past years, receive gratuities at the rate of 15s. for each year they or their husbands had subscribed. This is an excellent scheme; and we earnestly hope that additions to the Fund will be made, so that increased help may be given to those who need it.

LECTURE ON FRUIT GROWING FOR PROFIT.—A lecture on the above subject was delivered by Mr. D. BUCHANAN, Forth Vineyard, Kippen, in the Canrick Street Hall, Ayr, on the evenings of Thursday and Friday last, under the auspices of the Ayrshire Gardeners' Mutual Improvement Association. Mr. JAMES BOYD, Stewartlea, Vice-President of the Association, presided, and there was a large attendance both evenings. The lecture was of considerable length, and Mr. BUCHANAN laid most stress on the profits likely to arise from fruit-growing as it can be carried out in Scotland, touching upon the cultivation of Apples, Strawberries, and Gooseberries out of doors, and of Grapes and Tomatos under glass, going pretty fully into the economical side of the question.

ROSA GIGANTEA.—We were informed some days ago that a plant of this species in the garden of Lord Brougham, at Cannes, had some thirty flower-buds upon it, most of which have probably by this time expanded.

CAPE FRUIT.—The Union Steamship Company's steamer *Guelph* has arrived with 594 boxes of Grapes. Unfortunately, all arrived in very wet condition, and realised poor prices.

STOCKTAKING: MARCH.—It is worth noting here that the authorities at the Board of Trade are endeavouring, month by month, to get at the seat of the production of all goods imported into this country from whatsoever quarter shipped. It has been the habit to class as German, or otherwise, all goods sent for shipment to German ports; this has been found to be very misleading, and the seat of origin is now in many cases found in the Board of Trade returns, which, for the month of March, are more satisfactory than those for the two preceding months. The imports for the month amount to £43,412,829, against £40,655,114, or an increase of £2,757,715. The bulk of this increase is found under the heading of "articles of food and drink, duty free," and the figures here are £2,347,085. As we had previously noted, there was a large amount of cereals "on sight" in the United States, and they have sent for the greater part of this increase—Wheat, flour, Indian-corn, bacon, and lard; Russia, the Argentine, India, and other countries, making up the difference. Australia sent an additional £149,000's

worth of mutton. There was also an increase in the imports of timber, amounting to £114,777. The only decrease of articles other than food and drinkables are to be found in—(1), metals, £6,105; (2), chemicals, &c., £260,653; (3), miscellaneous, £14,582. The following are our usual excerpts from the "Summary" Table:—

IMPORTS.	1897.	1898.	Difference.
Total value ...	£ 40,655,114	£ 43,412,829	+ 2,757,715
(A.) Articles of food and drink—duty free ...	12,547,692	14,894,777	+2,347,085
(B.) Articles of food and drink—dutiable	2,353,448	2,242,124	—111,324
Raw materials for textile manufactures ...	7,587,037	7,737,056	+150,019
Raw materials for sundry industries and manufactures	3,381,380	3,635,334	+ 253,954
(A.) Miscellaneous articles ...	1,412,210	1,397,628	—14,582
(B.) Parcel Post ...	74,896	141,117	+66,251

The next point of interest is the supply of fruits, roots, and vegetables, concerning which we give the following figures:—

IMPORTS.	1897.	1898.	Difference.
Fruits, raw:—			
Applesbush.	618,219	160,779	—457,440
Cherries
Plums	6	90	+84
Pears	1,796	3,153	+1,357
Grapes	3,205	1,649	—1,556
Unenumerated	58,065	68,701	+10,636
Onions	301,052	272,059	—28,993
Potatoescwt.	45,203	635,872	+590,669
Vegetables, raw, unenumeratedvalue	£168,432	£109,289	+£857

The countries whence Potatoes are derived are Germany (321,310 cwt.), France, Channel Islands, and "other countries." Respecting France, a recent return states that the consular district of Cherbourg sent us 24,173 tons last year; of fresh vegetables, 3209 tons; of fruit, 2129 tons. The imports for the three months reached the total of £119,099,209, against £117,633,863 in the same period of 1897—or an increase of £1,465,346.

EXPORTS.

In the matter of exports we have still to deal with the late strike of engineers, and at a later period the coal dispute in South Wales will have to be reckoned with. The exports for March amount to £20,833,865, as against £21,647,269 in March, 1897—a decrease of £813,404. The only items showing an increase are in "animals living," £9,208; and "raw materials," £12,582. The greatest decrease is found in "metals and articles manufactured therefrom, except machinery, £248,924; yarns and textile fabrics, £208,766; machinery and millwork, £134,198; articles of food and drink, £91,776; chemicals, &c., £74,561; apparel and articles of personal use, £69,672; by the way, there was a large increase in the supply of cotton goods to India, but the falling off in woollen and linen manufactures far outbalanced it; the demand from the United States has decreased considerably. There was a rise in coal, but the decrease in wool wiped that out of the reckoning. A large increase in the trade with China may, we are assured, be expected to follow the recent arrangements with the Court of Peking; already inquiries for ships have been made here by agents from Russia and Germany, to be freighted with British products, principally iron and steel manufactures. But we will soon see. Meanwhile, there is little doubt as to seeing the British flag on the far inland waters of the Celestial Empire. The export for the three months foot up at £57,707,118, as against £59,298,187, or a decrease of £1,591,069, or 2·7 per cent.

NATIONAL AURICULA AND PRIMULA SOCIETY (SOUTHERN SECTION).—The twenty-second annual

exhibition of the above Society will be held at the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, April 26. Notice of entry, and of the classes proposed to be shown in, must be given to Mr. T. E. HENWOOD, Auricula Villa, 16, Hamilton Road, Reading, at least four clear days before the day of the show.

LINNEAN SOCIETY.—On the occasion of the evening meeting on Thursday, April 21, at 8 P.M., the following papers will be read, viz.:—1. "On the Structure of *Dendroceros*," by Prof. DOUGLAS CAMPBELL, F.M.L.S.; and 2. "On the Pterylosis of the Owls," by Mr. W. P. PYCRAFT.

PUBLICATIONS RECEIVED.—*Journal of the Board of Agriculture*, March, 1898, treating, among other subjects of: The Potato and Hay Crops of 1897; Imports of Agricultural Produce, 1897; Agricultural Trade of Australasia, and Injurious Insects.—*The Canadian Horticulturist*, March, 1898, includes papers on: Orchards and Gardens of Orillia; Pruning Grape Vines; Tomatos for English Market, &c.—*Dictionnaire Pratique d'Horticulture*: This work now reaches the letters T A I L, and the last livraison published includes a coloured plate of *Tacca cristata*.—*European Mail*.—*Nature Notes*, April.—*Palmae Mattogrossenses*, J. Barbosa Rodrigues, Rio de Janeiro.—*Müller's Deutsche Gärtner-Zeitung*, April 2.—*The Florist's Exchange*, March 26.—*Royal Society of Canada*, Vol. II.—*Generic Characters of the North American Taxaceæ and Conifereæ*, by P. D. Penhallow.—Vol. III. *Review of Canadian Botany*, by D. P. Penhallow.—*English Mechanic and World of Science*.

GERMANY.

SOME NOVELTIES.

AMONG the many novelties of the last few years, emanating either from Stuttgart, or which have been tried here, the following are deserving of notice:—

Anemone japonica Queen Charlotte (of Wurtemberg).—A grand hybrid of Mr. Pfützer's, which flowered for the first time last autumn. It is a beautiful, extra large-flowering, semi-double variety, of a delicate silky flesh-rose, and with a somewhat darker reverse. In colour it is very similar to *Anemone japonica elegans*, but has flowers almost twice its size, combined with a neat and compact habit.

Ageratum Princess Pauline.—A very pretty dwarf variety, about 5 inches high. The body of the flower is white, with a delicate outer border of sky-blue, making same peculiarly effective.

Cobaea scandens foliis marmoratis (Pf.).—A very pretty climber, with light green leaves, which are blotched and speckled and sometimes even bordered regularly with white. Grown in pots or planted out in a temperate-house it is very decorative.

Cactus Dahlia, Charlotte Deegen, raised by Mr. Max Deegen in Köstritz, has rather a tall habit, but flowers very freely, and continues to do so until late in the autumn. The flowers are of a delicate lemon colour, and well incurved. It has long and stout stems, and is a very desirable flower for cutting purposes.

Lobelia "Klothilde Pfützer."—This variety deserves to be better known. It is the darkest we possess here. Flowers are indigo-blue, with a clear white eye.

Giant Fringed (or Frilled) Tuberous Begonias.—This is undoubtedly the best strain that has as yet appeared in single tuberous-rooted Begonias. They occur as yet in purple, scarlet, vermilion, and various fine shades of salmon and orange, and apart from the clearness and beauty of their large flowers, they are all more or less delicately fringed, adding greatly to their charm.

Pelargonium "Wilh. Langguth," belonging to the Mrs. Parker class, which it resembles. The flowers are dark rose, slightly flushed, having a robust and compact habit.

P. Meteor (Goeschke).—A fine single variety, both for pots and groups. The flowers are of an intense dark cinnabar red, forming very large umbels.

P. Alphonse Martin.—Also a very fine single variety, one of the best, is rose-coloured with a white eye, similar to the old favourite variety, "Queen Olga," which is still much planted here. It is very large-flowering.

Nicotiana collosca variegata.—If this variety has not fully realised what was expected of it, it can still be recommended for a number of purposes. As a pot-plant it is very effective, whilst in the open it succeeds best when planted in batches of three or five in a snug sheltered position, as can be seen at the Palmengarten, Frankfurt-on-the-Maine, during the summer months. We also use same as the centre-

ARTHROPODIUM CIRRHATUM.

FOR the past three years, I had among the collection of plants recently under my charge a number of nice specimens of this little-known New Zealand plant. Originally a small packet of seed was handed to me labelled "Lily, Mabel Island, S. Pacific. These were sown, and came up pretty freely, and some fifteen plants were grown on. When they flowered, the spikes were quite unknown to me, and to several others to whom they were shown.

I was afterwards successful in getting the name from Kew (that happy storehouse, that has been a friend to so many like myself). Since then I have

were mostly secured by Messrs. R. Veitch & Sons, of Exeter, who doubtless will assist in their being further spread abroad.

When the seed germinated, I grew the plants at first in an intermediate house, where the leaves grew rather lengthily. I then, for the summer, stood them in a cold frame, and the lessening of the temperature with greater humidity had a most marked effect. The foliage became stouter, deeper in colour, and a vigour was developed of which first appearances gave no indication.

Towards October or November, the plants were brought into the warm greenhouse and continued growing, so that during February and March the

FIG. 86.—ARTHROPODIUM CIRRHATUM: FLOWERS WHITE, $\frac{3}{4}$ TO 1 INCH ACROSS, WITH A PERIANTH OF SIX PERSISTENT SEGMENTS.

piece in groups. The lower part of the plant is thus hidden, and as it is very liable to lose its lower leaves, this is an advantage.

Pennisetum Rüppelianum.—An introduction of Messrs. Dammann, Naples, which is really good. It has been very aptly compared with a dwarf Gynarium. It grows about 1 foot high, and with its exceptionally fine and gracefully-drooping leaves and dark brown flower-spikes, is very suitable as a border to groups of foliage plants, such as Canna, &c. We had a large group of Cannas last year, centre R. P. Ker, dark red, enclosed with Fürst Hohenlohe, yellow, the whole finished off with Pennisetum Rupp., which was very fine. H. R. W., Stuttgart, March, 1898.

found it in *Nicholson's Dictionary*, and now I have before me vol. i. of the *Gardeners' Chronicle* for 1874, and on page 661 is a plate representing a well-grown flowering plant, with on another page numerous other wood-cuts of flowers, pollen, stamens, &c., all remarkably true to the specimens I have flowered.

Regarding that figure [which is here reproduced. Ed.], I should like to say that a plant with me of such a size and vigour would have had six to eight spikes, and when these come up well above the foliage, their purity and attractiveness always made them objects of interest. I much regret having to be severed from these and many other interesting subjects, but it is a pleasure to know they

spikes appeared, no any laterals being produced on the spikes. I certainly recommend it to be grown in gardens where a conservatory must be kept continually gay, since its bright flowers coming freely above the foliage, give a novel, attractive, and pleasing interest to the collection.

It is a plant of free growth, and makes very fleshy roots; if grown so that pots of 6 or 8 inches are used, these will be plenty large enough; then after flowering, the plants may be divided, and the stock easily increased. If care is exercised, the flowers will produce a quantity of black-looking seed; this should be carefully sown and tended, as it will quickly germinate, and nice plants soon be formed.

Though much like one or two of the greenhouse Anthericums, it must not be confounded with them, as it is in every respect a much better thing. *W. Swan, Bystock.*

HOME CORRESPONDENCE.

THUNBERGIA LAURIFOLIA.—What a very handsome stove climbing plant we have in the above-named variety of Thunbergia! For flowering at this time of year I know of no other to equal it. In the stove here there is a good sized specimen, which has been in flower for some time past, and is yet almost smothered over with its long racemes of beautiful pale blue flowers. It is of very easy culture. Our plant is growing in a square wooden box, fixed some little distance above the four hot-water pipes that run round the house underneath the side stages. The growths are trained up the roof on a wire trellis fixed about 8 inches from the glass. The house in question is a span-roofed one. The plant is growing in a compost consisting originally of equal parts of turfy loam and good peat, with an admixture of clean river sand and small bits of charcoal. The whole is now a mass of roots, requiring a plentiful supply of water at all times, but especially during the summer months, when the plant is making its annual growths. About the end of April we thin-out the worn-out shoots, leaving a thin covering of the younger ones to form a base for the supply of flowering growths another season. A top-dressing of fresh compost, with an occasional sprinkling of some good artificial manure during the summer, is all the attention required. Unfortunately, the flowers are not useful in a cut state, which to some may be a drawback. I am forwarding a few racemes of flowers for your inspection. When looking through the houses at Messrs. Backhouse's York Nurseries, recently, my attention was drawn to a very large specimen full of flowers in the stove. The foreman told me it had been in the same condition for some weeks past. *H. J. C. Grimston, Tudecaster.*

HARDY PLANTS FOR FURNISHING FLOWERS FOR CUTTING.—I cannot allow to pass unchallenged the recommendations of Mr. Ward under this head at p. 205, concerning bulbous Iris (i.e., English and Spanish), and double Daffodils, more particularly as regards the planting of dry bulbs of these things in spring. Mr. Ward says, "There is no practical reason" why good dry bulbs of these Irises and double Daffodils shall not be planted in February or March. To this I can only say there is every reason possible, for if such bulbs were planted 3 inches deep in either of these months, after having passed the usual ordeal of the bulb drop, the chances are that 90 per cent. would never raise themselves that year more than the same number of inches above the soil, and by reason of the almost if not entire absence of roots, no foliage worthy the name would result, and with such where does Mr. Ward get his new bulb and flower germ for flowering another year? And yet this is the advice tendered by Mr. Ward, that, "By doing so they gain time and strength, and give better floriferous results." I am quite prepared to waive the months of February and March in this matter, and then to state that even January-planted bulbs—which of necessity would be more sound than the same things kept two months longer—invariably reach only half their usual size, and when taken up are found to be crippled in a far greater degree than any hard-forced bulbs. How much worse, then, such as are recommended for March, or even later? Mr. Ward urges that I must know that thousands are advertised and sold in the months named. True; but who are the buyers? Certainly not practical gardeners or bulb specialists. Only in February of this year I was an eye-witness to the sale of part of a big lot of double Von Sion Daffodils, put up in lots of 500 each. The first started at 2s., and eventually the lot, all good-sized bulbs in a dry state, reached 3s. 6d. This for bulbs of forcing size of double Von Sion. There were other lots of equal size, for which no bid could be drawn out of a large company, that included at least half-a-dozen Daffodil-growers and specialists. Here was a lost opportunity, for Mr. Ward could have had at least 2000 or 3000 for the taking away; bulbs, moreover, that, as far as size was concerned, were equal to many selected for forcing, and costing in their rightful season from 35s. to 40s. per 1000, exclusive of carriage, package, &c. Spanish and English Irises are even worse to keep sound, as no group

of hardy bulbs or tubers is more susceptible to dry-rot than these when kept long in a dry state; the only other group that I can compare with these is the Erythroniums, and these suffer from the same cause, and probably to a greater extent in a short time than do the Iris. Respecting the Francoa, to which Mr. Ward refers again, I must state that he originally recommended it for field-culture, and quite unconditionally, and to say that it will "grow and flower freely when sheltered from north and east winds," is trying to evade the point at issue. Given field culture in the open, this plant cannot with impunity endure 12° of frost, yet this is the subject Mr. Ward recommends the flower-farmer to grow for profit. Over and over again in the very light soil of this district, which is also well drained, and likewise at Tooting, in an ideal soil for the comparatively hardy subjects, all the stock left out in the plunging beds, notwithstanding the plants were deeply rooted into the soil below, were killed outright, always in cases of ordinary severe frost; not only *F. ramosa*, but *F. sonchifolia*, and *F. appendiculata*, the last the deepest coloured form of all. This is not the plant the flower-farmer requires at all, or if he does require it, he should at least know that he is dealing with a somewhat tender subject. *Thalictrum adiantiforme* is also mentioned by Mr. Ward for the same purpose. A pretty rockery plant certainly, but unfitted as a plant to grow for cutting for profit. In the first place the pinnate-like foliage has been much over-rated, the young growths won't stand at all when cut, and the more mature fronds, so to speak, are not ready till August, when such a subject would be valueless in our markets. Furthermore, the yield of an ordinary plant is not more than half a dozen fronds each year till tufts are formed, and it is not a very productive plant. A useful enough subject in a private garden, where if given moist sandy soil, or with peat added, growth is more free. Under field culture, however, unless its requirements were nicely adjusted it would take several years to establish—in short, it is not at all suited for the purpose in a general sense. A list of some "good perennials" requested by Mr. Ward is already in the hands of the editor of the *Gardeners' Chronicle*, and may see the light and I hope also "do a service" in the near future. *E. Jenkins, Hampton Hill.*

COLOUR IN DAFFODILS.—I read with interest your remarks in No. 586, March 19, p. 172, "On the colour of Daffodils in relation to Soil." I have tried a good many experiments with the Hydrangea, as I wished to secure a permanently blue strain, but without success hitherto. Some years ago I noted in the Pass of Aberglaslyn some very fine blue Hydrangeas, of which I obtained cuttings, and tried various experiments, using steel filings, alum, and sulphate of iron, but without success, for all reverted to the pink, or, as it is sometimes called, purple colour. Another time I obtained cuttings of the blue variety of Hydrangea from Penmaenmawr, and secured about a hundredweight of the actual soil they were growing in to strike and grow them in, with but slightly better results, for ultimately all of them reverted to the pink colour. In travelling, I have noticed, in parts of Cornwall, where broken shells—shell-gravel from a part of the coast where shells abound, was used as manure on part of a field, that the colour of the grass was of a much deeper green than in adjacent parts, and as if the inhabitants of the district knew what effect this shell-lime or chalk would have. One man had written his name in large characters, and it came out bold and clear in dark green against the paler grass. What had taken place, I think, was the lime had liberated the ammonia which was in the ground from the sheep and cattle-droppings, and thus given rise to a strong manurial effect. Again, I have constantly used weak sulphate of ammonia to give richness and intensity of colour to my Primulas, and with uniform success. Now, what I want to come to is this. Blue Hydrangeas are very frequently found on moorland, where peat abounds; peat very frequently contains iron. Last year, whilst in Ireland, on Slieve Donnard, the highest point of the Mourne Mountains, near Bloody Bridge, at the back of Newcastle, Co. Down, my son gathered a blue Heath in the peat. Again, if very rich purple Aubrietias are transplanted to a lightish sandy soil, the colour becomes poor and washy; and just the same takes place with blue Hepaticas. Why was not the soil looked at as a mechanical medium for the plant to grow in? or was it the lightness of the soil allowed the chemical salts to be washed out, and so the plants were deprived of that which was essential to

maintain the rich blue colours. How was the so-called blue (purple) Chinese Primula obtained a few years ago? How, more recently was the blue Primrose obtained? Any information as to how the colours of flowers may be changed by soil or chemical salts would oblige. *Hy. Ashwell.*

SPARROWS AND CROCUSES.—As "Wild Rose" (p. 204) says, "the ways of that little depredator, the sparrow, are unaccountable." I must plead guilty to harbouring the sparrow, and not only feed it, but allow it to build among the Roses on the house. Whether or not gratitude is one of the virtues of the much-maligned bird, it never returns evil for good by destroying the flowers here. Crocuses of all colours bloom freely and are left untouched by the birds, while in a garden only a mile away, not only yellow Crocuses, but Primroses, Polyanthuses, and Hepaticas are destroyed. A well-informed naturalist with whom I discussed the question two or three years ago, said that he believed that some families of sparrows were free from this habit of destroying the flowers. One would fain hope that the birds here may not fall into the depraved habits of other places, but will allow us to enjoy our flowers without the disfigurement of black threads—the only preventative of which I have ever heard. Perhaps some one who has lost flowers from the attacks of the sparrows would try giving them food and water for a year or two, and report after that time. [Vain. Ed.] Slugs are very destructive here, but except in the case of some specially-prized plants, leave the Chionodoxas alone. They are very destructive to the Puschkinias, and *Bulbocodium vernum* is scarcely allowed a perfect flower, so severely do they crop it, although almost daily search is made for marauders near where it grows. *S. Arnott, Carsethorn, by Dumfries, N.B.*

ROYAL GEORGE APPLE.—I could not resist the appeal made to me by Mr. Geo. Bolas on p. 172 (*Gardeners' Chronicle*, March 19), to verify my first statement by some account as to the origin and approximate date of same of Royal George Apple, and its entry into commercial life. The last item I am unable, even now, to give any information upon. I did the best I could in the matter by sending the whole of the correspondence to Mr. George Beaumont, of East Bridgeford. Mr. Beaumont is a land agent of wide and varied experience, has lived all his life in East Bridgeford, and is deeply interested in the local history of the village, its people, and all its concerns. He is also a member of the Notts County Council, and well read in the county's history. He very kindly supplied me with the following note:—

"ROYAL GEORGE APPLE, OR CLARKE'S PIPPIN (NOT SEEDLING).—Whatever Apples may have existed before under this name, the original tree, now called Royal George, was grown by Mr. George Clarke, or Clark (the name is spelt both ways), a master bricklayer, who lived and died at East Bridgeford, from which very many trees have been grafted, and the sort is now extensively grown even by Messrs. Pearson and Merryweather, and can be traced to that origin. I have one tree which must be over fifty years of age. My late gardener, George Upton, had four trees; his son, now in my garden, another. Clarke's son, now living, has the original tree, or at least it still grows in his late father's garden. You have, as you say, awarded prizes for this fruit, which is very handsome. Mr. Hassall, of Shelford Manor, has many trees, and my man, John Upton, says that there are 'hundreds' grown in these parts. Thomas Clarke (whom I also know well and employed), is, like myself, now past seventy years of age, and remembers the tree from his youth. There is no doubt, whatever that you are correct, and if you want proofs, they can be found abundantly here.

"GEORGE BEAUMONT, F.B.I.,

"East Bridgeford, Nottingham, March 29, 1898.

"Mr. Pownall."

I think I need only add that I am delighted to have so emphatic and clear a confirmation of my contention as to the origin of the Royal George Apple. *N. H. Pownall, Lenton Hall Gardens, Nottingham.*

APPLE, GASCOIGNE'S SEEDLING.—My opinion of this showy Apple agrees with Mr. Markham's, but I ought to mention, however, that my experience is confined to young trees, planted in the autumn of 1893. This variety, Bramley's Seedling, and Annie Elizabeth, have so far proved to be the most shy croppers, amongst some fifty others, planted in pyramidal and bush form on the above date. It forms a handsome bush, and grows very freely; in fact, it and Bramley's are the most vigorous growers that we possess—an attribute which amounts to a defect—and, notwithstanding root-pruning, trees refuse to bear well. As the trees advance in age and exhaust the maiden soil in which they were planted, they may become better croppers. Gascoigne's is prone to form fruit-buds upon the points of the shoots, and for this reason it is not so well adapted as many others as an espalier-tree. *Thomas Coomber.*

ALSTRÖMERIAS.—The discussion regarding these beautiful flowers must have been of interest to many besides those who grow flowers for market purposes. Of those in cultivation, I believe *A. aurantiaca*, with its variety *aurea*, *A. chilensis*, and *A. psittacina*, to be the hardiest. In some gardens, even mild localities, all of these may be lost however in a way difficult to understand, while in others in the same neighbourhood they increase in size from year to year. What is particularly puzzling is the way in which large plants established for some years disappear in one winter. I have known clumps of *A. psittacina* vanish thus in even milder winters than that of 1895-96. I fancy from what we know of the plant, that neither *A. pelegrina* nor *A. p. alba* are likely to be suitable for outdoor cultivation, except in warm and sheltered positions in exceptionally favoured localities. Among others I have tried but lost, are *A. Errebaulti* and *A. versicolor*. Growing well at Newry, and in front of the houses at Glasnevin, I saw both *A. Diazii* and *A. revoluta* two years ago. There was a plant of the latter in this locality last year, but I have not heard if it still survives. I believe much depends upon the soil in which *Alströmerias* are grown, and the attention they receive by watering in summer, and the addition of a covering of litter in winter. *S. Arnott, Carsethorpe, by Dumfries, N.B.*

STOCK PRINCESS ALICE.—I am sending some flower-spikes of Stock Princess Alice, cut from plants raised from seed sown last September, pricked out into 60's, and when large enough potted into 48's in January. I have a good number of them which began to make a pretty display in the conservatory in March, and they will continue to flower throughout the present month. When out of bloom I shall cut them back, and when well broken plant them out in a rich border to flower in July and August. I proceeded in the same manner with my Stocks last year, and the autumn being mild, they flowered for the third time before the frost spoiled them. I may say the flowering in pots was not so good as this year. The Stocks from which I send you flowers had the points of their shoots nipped off about ten days after they were potted in 48's. *H. Brewer, Oaklands, near St. Albans.* [Nice flower-spikes of this fine white variety of Stock. Ed.]

IBERIS STYLOSA.—This is Tenore's name for a rather obscure dwarf Neapolitan plant, which Nyman in his *Conspectus Fl. Eur.* classes—apparently on his own authority—under *Thlaspi*, but the *Index Kewensis* and *Kew Hand-list* refer it to *Nocca*. It appears this spring offered as a rare novelty in several nursery catalogues, and as these I have obtained from several nurseries for the purpose of making its acquaintance do not all agree, I send this note about what I conclude to be the true type. It is an insignificant but neat little plant, not at all like an *Iberis* in general appearance, an inch or two high, with small flowers of a pale purple tint, produced very early in spring, and about the size and shape of those of *Hutchinsia* (*Nocca*) *alpina*, which the plant somewhat resembles, except that *H. alpina* has white flowers. I am doubtful whether the plants will survive one flowering. In merit it will hardly supersede the better known annual *Ionopsidium acaule*, which is nearly related to it, and which flowers in the crevices of rockeries abundantly all the autumn, winter and spring, and if we wish it, all the year round, being very neat and never obstructive. The colour and size of both flowers is similar. *C. Wolley Dod, Edge Hall, Malpas.*

NARCISSUS ATTACKED BY MITE.—I send some bulbs of *Narcissus* infested with what I term bulb mite, *Rhizoglyphus echinopus*. Imported bulbs of *N. nanus* are injured in the same manner. The bulbs are infested outside by the mite and other insects; one a semi-transparent worm-like thing, another white semi-transparent insect with legs; both these I have always found associated with mite. [All, perhaps, prey on decayed vegetable matter. Ed.] My attention was drawn to the plants by their miserable appearance, for they used to make a grand show out of doors, and were bulbs that had been forced and then turned out in some numbers each year for the last eight years. From the appearance of the dead tipped foliage and absence of bloom, the bulbs seem doomed to extirpation by the mite if left alone—such being my experience here. About this time last year an exhaustive article appeared in the *Gardeners' Chronicle*, the writer arguing against the destruction of *Narcissus* bulbs by the mite, or at least, if my memory does not betray me, the writer

stated that no proof was forthcoming to prove that mite was the cause of the decay so common in *Narcissus* (either I do not know the mite when I see it, or the writer is mistaken), as there is mite here in the soil which we obtain from the park, and it is also imported in the bulbs themselves, and nearly every plant with a fleshy root is sooner or later infested, with the result that many species of plants we cannot grow at all; so that it has become a plague in this garden. But my object in sending these bulbs is to prove that the writer of the article in the *Gardeners' Chronicle* last year was mistaken. I will give some certain remedies against mite on bulbs in a future note, and the names of the other plants attacked, as we, I should imagine, stand at the top of the tree here for vermin and garden pests; indeed, we do more to fight them than to grow plants. *Geo. Abbey, junr., Avery Hill, Eltham, Kent.* [Mite was found in the bulbs, and small earthworms and millipedes, the last two not destroyers of plants; and the bulbs were badly decayed at the base, and for some distance upwards; indeed, no healthy roots whatever were found on the bulbs. No mite was discovered in sound parts of the bulbs. There must be something inimical to these plants in the soil. Ed.]

IMPORTED ONIONS.—The common sale in this country of Brittany Onions, to which Mr. Herrin draws attention on p. 213, is due to several causes. First, France exhibits in a degree far beyond any English experience the productive value of the small-holding system. It is in the hands of the industrious and, as this case shows, energetic peasantry of France a wonderful power in production, excelling all our ordinary farming methods a long way in that respect. In France, wages are low, but, then, living is with them simple and inexpensive. Myriads of our workers spend as much on beer and tobacco as would keep a French peasant. Then we see in the action of these peasants in combining together for the purpose of chartering vessels and sending their Onion produce over here, to be disposed of by themselves or their agents, that co-operative effort which is in this country so much lacking. The Onion is essentially a garden crop. To obtain profitable results, deep culture and high manuring is absolutely needful. That is in the small-holding system, conducted by manual labour, well done. We see evidence of what can be accomplished in that way in splendid Onion crops in private gardens and on allotments. We see no such great results on ordinary farm land. There is no crop produced of a strictly bulbous nature that is, on the whole, heavier than is a good one of Onions. I have seen at the rate of 5 bushels per rod produced under good culture, and of course a fine sample. That is a rate of production that should pay well, especially that ground well prepared for Onions is in splendid condition to carry some other crop the succeeding year, especially one of strong, well-rooted Strawberry plants, put out thickly to carry one crop, then to be trenched in, and got ready for Onions again. It is worthy of note that Mr. Bowerman, at Hackwood, grows his grand planted-out bulbs every year on the same ground, and finds it is improved annually. *A. D.*

LAW NOTE.

AGRICULTURAL RATES ACT.—SMITH AND OTHERS v. RICHMOND.

THE Court of Appeal reversing the judgments of the Courts below, has held that "glasshouses" are not to have the benefit of the relief given by the Agricultural Rates Act, 1896, to "Market Gardens and Nursery Grounds."

Having regard to the importance of the question to growers, my Association has determined to carry it to the House of Lords, if we can secure the support of the trade generally. We have many calls on our funds, and it is felt that the serious expense involved in proceedings of such wide-spread interest should not be wholly thrown on the subscriptions of our members. Growers throughout the country are invited to inform our Treasurer, Mr. George Munro, by letter addressed on or before the 30th inst. to the offices of the Association, as below, what financial support they are, under the circumstances, prepared to afford the Association.

I am, yours faithfully,

WILLIAM POUPART,
President of the Market Gardens, Nurserymen,
and Farmers' Association.

32, King Street, Covent Garden, London, W.C.,
April 14, 1898.

BELGIUM.

NURSERY NOTES.

L'ETABLISSEMENT HORTICOLE (LINDEN'S).

A VISIT to this well-appointed nursery in Brussels, is at all times of interest to the horticulturist, but it becomes all the more so prior to the "Ghent Quinquennial." One cannot but admire the excellent arrangement of the glass structures, nearly all of which have span roofs, and in every case they open into a lofty, long, and wide corridor, down the centre of which are disposed many splendid specimens of the best of our well known species of Palms, and not a few of rarer species. Several of these Palms are noble examples, and comprise *Kentias*, *Latania borbonica*, and *Cocos Bonnetii*. These Palms are set off by small specimen Aroids, *Anthuriums*, &c., a complete finish being given by means of a close carpet of creeping-plants and others of lowly growth well adapted for the purpose.

At one end of this erection is a winter-garden, which forms the chief entrance to the glasshouses. This, too, has amongst its occupants numerous fine specimen foliage plants. Palms, of course, predominate here also, but there are some huge specimen Ferns, and there is at the other extremity of the first-named corridor a big plant of *Cibotium Barometz*. On a stage in the winter-garden many new, rare, and interesting plants are arranged, which are set off by a carpeting of green moss.

Orchids predominate in the span-roofed houses issuing right and left from the corridor. In one of the largest of these I found a remarkably fine lot of *Vanda suavis* and *V. tricolor*, many of them flowering profusely. These *Vandas* are abundantly furnished with healthy leaves quite down to the rims of the pots. Plants of *V. Batemanni* were also noted here some 6 or 7 feet in height, and these, too, with foliage down to the base. *V. Kimballiana*, one of the smaller growing species, was also noticed in a thriving condition. In this and in another house an importation of plants of *Oncidium Lanceanum*, well established and rooting freely, was observed. Several houses held a large number of plants of *Cattleya Trianaei*, *C. Mendeli* and *C. gigas*. Of the old *Cattleya labiata* with the typical broad leaf, a large stock of plants was noted in one of the houses. *Cattleya bicolor* as flowering plants in quantity, was also included. Of *Lælias* the chief stock consisted of *L. purpurata*, of which in one of the houses an unusually fine stock furnished with many sheaths was noted; *L. præstans* and *L. autumnalis* were also present in considerable numbers. Another Orchid, not seen often enough in gardens, was also making a capital display, viz., *Cœlogyne ocellata*. Other well-known Orchids which here are thriving very satisfactorily are *Oncidium crispum* and *O. Marshallianum*; and *Cypripediums* are to be seen in quantity. The most notable of this family of Orchids are *C. bellatulum* and *C. villosum*, both of which have been recently imported with *C. Parishii* together. Of hybrid *Cypripediums* there are many healthy plants, and of these *C. Schroderæ* and *C. grande* claimed especial notice; *C. Lawrenceanum* was also strongly in evidence.

Just at the present time, however, the finest display is being made with *Odontoglossum luteo-purpureum*, of which healthier plants or finer varieties could scarcely be found elsewhere. Many of the finest spikes carried twenty or more flowers of large size, which glistened with the brightness of perfect condition. These last-named plants were scattered through several of the houses, and formed a truly notable feature, being represented by hundreds of spikes. *O. cirrhosum* was beginning to expand its flowers, which showed many good forms. *Odontoglossum* (*Miltonia*) *veixillarium*, although but a few were in flower, gave excellent promise, and the plants are sending up flower-spikes in great profusion, with that rude luxuriance of growth one desires to see in this Orchid. *Masdevallias* are to be found here in large numbers, the best species, as *M. Harryana*, being the most conspicuous, but of *M. Chimæra*

there were also some good specimens. The *Mormodes*, *Catasetums*, and *Anguloas* evidently find favour in Belgium, if one may judge by the large numbers grown in this nursery. Throughout the establishment cleanliness, and good taste in arrangement prevail. *Visitor*.

SOCIETIES.

ROYAL HORTICULTURAL.

APRIL 12.—Although the meeting on Tuesday last at the Drill Hall took place immediately after the holidays, there was no evidence of this fact in the hall itself, for the exhibits were numerous and the attendance large. There were many fine Orchids exhibited, including the spike of *Eulophiella Peetersiana* from Sir Trevor Lawrence's garden, and recently figured in these pages. Spring flowers were again numerous, and there was a good display of Daffodils, which made many batches of bright colour. Hybrid *Cinerarias* from Messrs. SUTTON & SONS and Messrs. JAS. VEITCH & SONS caused considerable attraction, being admired by many, but not unanquously. There was but a small quantity of fruit staged, though there were fine Strawberries and excellent Figs.

Floral Committee.

Present: W. Marshall, Esq. (chairman), and Messrs. Jno. Fraser, Owen Thomas, C. T. Druery, R. Dean, J. H. Fitt, Geo. Stevens, Wm. House, J. F. McLeod, Thos. Peed, C. J. Salter, J. W. Barr, J. D. Pawle, H. J. Jones, Chas. Jeffries, Chas. E. Shea, Chas. E. Pearson, D. B. Crane, E. Beckett, F. J. Cutbush, Geo. Paul, J. Fraser, E. T. Cook, Harry Turner, and Ed. Mawley.

Messrs. JNO. LAING & SONS, Forest Hill Nurseries, made a pretty display, with plants of their "multiflora" strain of *Streptocarpus*. They are free-flowered, embrace varied and pretty tints, and continue to flower for a very long period. The group was set on a groundwork of Ferns.

Mr. W. RUMSEY, Joyning's Nursery, Waltham Cross, made a bright show with a large number of cut Roses in much variety. H. P. Mrs. Rumsey was shown very finely, and with long stems attached, which seemed to show a vigorous habit in the variety (Silver Flora Medal).

Mr. J. WALKER, of Thame Nurseries, Oxon, showed about two dozen highly-coloured blooms of *Rose Maréchal Niel*, equally remarkable for their size as for colour (Silver Banksian Medal).

Another group of cut Roses came from Eastwell Park, Kent, Lord GERRARD's residence (gr., Mr. H. Walters). Two dozen specimens of *Maréchal Niel* in this collection were remarkably good in size and colour.

A large group of *Cinerarias*, interspersed with Ferns, from Messrs. J. CARTER & Co., High Holborn, London, showed a strain of large-flowered, brilliantly-coloured varieties, of a branching and moderately tall-growing habit (Bronze Flora Medal).

A group of *Cineraria* plants from Messrs. SUTTON & SONS, Reading, represented a strain obtained by crossing *C. cruenta* and *C. multiflora*. They are known as the "Stellata" group, and represent among *Cinerarias* what the "Star" strain is in *Primulas*. The plants were three feet or more high, slender habited, and possessed scanty foliage. The great characteristic, however, is extreme floriferousness; each plant produces branches of bloom well adapted for cutting purposes. The colours are varied, but not so bright as could be wished, and there was no white-flowered variety. Most of the plants were in 6-inch or 7-inch pots.

Messrs. W. CUTBUSH & SON, Highgate Nurseries, London, showed a group of forced flowering-plants, including *Cytisus laburnum*, *Staphylea colchica*, and *Deutzia Lemoinei* ×.

Messrs. W. BARDNEY, gr. to Sir PETER WALKER, Osmaston Manor, Derby, sent some blooms of seedling varieties of *Clivias*, several of which possessed much merit. Those named William Bardney and May Bardney were the best.

Messrs. HUGH LOW & Co., Bush Hill Park Nursery, Enfield, showed two plants of *Dracena aurea striata*, a broad-leaved *Dracena*, with a green ground, variegated with yellow (Award of Merit).

From Lord ALDENHAM, Elstree, Herts (gr., Mr. E. Beckett), came a small group of plants of *Deutzia gracilis variegata*, which to our mind is not so effective as the green-leaved type.

A pink flowered *Calla* was shown by Mr. G. TRINDER, Dogmersfield Gardens, Winchfield. The spathes were exceedingly small.

Messrs. R. WALLACE & Co., Kilnfield Gardens, Colchester, exhibited a few choice hardy plants in flower, including *Erythroniums*, *E. Hartwegi*, *E. giganteum*, *E. revolutum*, and *E. r. var. Bolanderi*, a pure white flower, save the yellow stamens, and a circle of the same colour in the eye. *Fritillaria pluriflora*, *F. lanceolatus gracilis*, *F. Whittallii*, and others; also the dazzling *Tulipa Greighii* and *Trillium erectum*, with deep crimson flowers, and a white variety of the same (Bronze Flora Medal).

On the floor immediately upon entering the hall, Mr. J. B. MAY, Dyson's Road Nursery, Upper Edmonton, arranged a group of Turner's Crimson Rambler Roses in pots, interspersed with variegated *Acers*, *Hydrangeas*, *Spiraea astil-*

boides floribunda, and Ferns; also several hard-wooded Clematises, Duchess of Edinburgh, white, double, and Miss Bateman, single white, and Begonias (Silver-gilt Banksian Medal).

Messrs. W. PAUL & SON, Waltham Cross, Herts, exhibited *Camellia* blooms in extensive variety, and inclusive of a few novelties. Awards of Merit were recommended to Pride of Waltham, a flesh-pink coloured flower of considerable size, with veining of a deeper colour; Mrs. J. Buchanan, a semi-double-flowered variety, white, irregularly marked with red; and Duchess of Teck, a good large flower of pale rose colour. Other new ones were Duchess of York, Camillo, Aureliana, &c. The group was recommended a Silver Flora Medal.

A collection of *Camellia* blooms from trees out-of-doors came from F. T. BURY, Esq., St. Leonard's Hill, Windsor, (gr., Mr. R. Brown). This collection of six dozen blooms was accorded a Vote of Thanks.

Mr. CHAS. TURNER, Royal Nurseries, Slough, exhibited three plants in baskets of *Nepeta glechoma variegata*, a very pretty hardy trailing plant (Cultural Commendation).

Mr. J. MILLER, gr. to Lord FOLEY, Ruxley Lodge, Esher, showed a lot of fine Violets Marie Louise, from plants that have been flowered for three years successively in frames. A few *Narcissus* blooms came from the same garden.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, again exhibited about half a dozen of their seedling *Hippeastrums* in flower, and an award of merit was recommended to one of these, viz., to *Daones*, having white and scarlet flowers, the segments in each case having a narrow white margin, a very pretty flower. They also showed a number of hardy plants in variety, including the neat-habited *Rhamnus alaternus fol. argenteis*, with effective white variegation; *Azalea carminata splendens*, possessing small flowers of a rosy-crimson colour; *Deutzia hybrida Lemoinei*, figured in *Gardeners' Chronicle*, vol. xviii., 1895, p. 389; *Rhododendron racemosum*, with pink flowers, closely set in the leaf-axils of the annual shoots—a good plant for beds in the open; *Rhododendron indica var. Kämpferi*, having red flowers; *Azalea obtusa var. alba*, small white flowers. This exhibit contained plants of *Cinerarias* raised from *C. cruenta* crossed with florists' varieties, that showed much variety of colouring, and mostly of gawky habit, with long-branched corymbs, and flowers resembling a now obsolete type in some cases, and of a stellate form in others. The plants are showy as at present seen, and appear well adapted for furnishing flowers for cutting, these lasting in good condition for a long period of time.

Mr. W. KEMP, The Gunyah, Barnes, sent a pretty collection of double and single flowered *Azalea indica* in small plants, each loaded with flowers, and mostly of very pleasing colours and form. The prettiest were *Othello*, Victor Cuvellier, Dr. Moore, Louis Lubbers, *Memorie de L. Van Houtte*, *Comte de Torre*, *Duchess Fernand Neumer*, *Madame Grève*, *Theodore Reimers*, *Princess Victoria*, *Baronne de Vriere*, *Madame Louise de Kerchove*, fifty-four plants in all, the group bordered in the front with Lily of the Valley in pots (a Bronze Banksian Medal).

Messrs. J. HILL & SON, Nurseries, Lower Edmonton, showed a choice collection of exotic Ferns in fine condition as way-going market plants. We remarked the following among the rarer species and varieties: *Dictogramma japonica variegata*, *Todea africana*, *Lastrea aristata variegata*, *Cheilanthes Ellisia*, *Osmunda palustris*, *Microlepia platyphylla*, with blue-green, boldly cut fronds; *Athyrium Gorin-gianum pictum*, *Pteris straminea*, and *P. arguta*.

P. PURNEL, Esq., Woodlands, Streatham Hill, S.W., showed a group of *Primulas*, including some few *P. auricula* in florists' varieties; *P. Allioni*, *P. viscosa*, *P. verticillata*, *P. intermedia*, *P. denticulata*, *P. ponderosa*, and seedlings of "blue" varieties, resembling Mr. G. Wilson's strain of these flowers.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, showed a large group of fine, fresh-looking Roses in pots, in bush and standard form. There were nice plants of *Madame Hoste*, *Souvenir de S. A. Prince*, *Madame de St. Joseph*, beautiful in the half-open state of the flowers as shown; *La France*, Mrs. G. S. Crawford, *Antoine Rivoire*, a one-flowered plant of the palest of flesh tints, deepest in tint in the unfolded petals; *Marquise Litta*, good in colour, a shade of crimson, but loose in form; *Clara Watson*, an immense bloom of this fine H. T.; *Rubens*, *Clothilde Soupert*, *Ernest Metz*, &c. An award of a Silver Flora Medal was made.

Orchid Committee.

Present: Sydney Courtauld, Esq., in the Chair; and Messrs. J. O'Brien (Hon. Sec.), De B. Crawshaw, R. Brooman-White, H. M. Pollett, H. J. Chapma, F. J. Thorne, W. H. White, W. H. Young, W. Cobb, T. W. Bond, H. Ballantine, and Major Mason.

Sir TREVOR LAWRENCE, Bart., Burford Dorking (gr., Mr. W. H. White), staged a select group, in which were several very remarkable species. In the centre of the group stood the grand inflorescence of the new *Eulophiella Peetersiana*, which produced its large clear rose, waxlike flowers for the first time under cultivation in the Burford collection, of which a flower-spike was shown of natural size in the *Gardeners' Chronicle* Supplement of April 2, 1898. The exhibit was unanimously awarded a First-class Certificate. Another grand exhibit in this collection was *Cypripedium* × *Olenus*, Burford variety, the largest and handsomest of the *C. bellatulum* hybrids ever shown. It was obtained from fine varieties of *C. bellatulum* and *C. ciliolare*, and the massive flower was almost entirely of a rich claret crimson

colour, a little of the white ground colour showing only at the edges of the sepals and petals (First-class Certificate). There was also shown for the first time *Masdevallia ventricularia longicauda*, one of a new section, with the base of the perianth formed into a long, pouch-like tube, the sepaline segments being small and furnished with tails about two inches in length, and the whole of a crimson colour (Botanical Certificate). Other remarkable plants in the group were *Cymbidium Devonianum*, with six long racemes of flowers (Cultural Commendation); the beautiful *Dendrobium* × *micans*, *D. lituiflorum* album, the richly-coloured *Odontoglossum Pescatorei* Prince of Orange, *O. nebulosum candidum*, a fine specimen of the brilliant *Epiphronitis* × *Veitchii*, with many spikes; *Dendrobium crepidatum superbum*, the charming *Polystachya Ottoniana*, forming a cushion of white flowers; the fringed *Dendrobium Harveyanum* *Epidendrum* × *Endresio-Wallisii*, *Masdevallia leontoglossa*, &c. The group was "not for competition."

Baron Sir H. SCHRODER, The Dell, Staines (gr., Mr. H. Ballantine), showed a few magnificent *Odontoglossums*, among which the fine, heavily-spotted *O. crispum* *Schroderianum* showed itself as still being one of the best; the unique *O. excelens* *Dellense*, of a very fine yellow hue, blotched with red-brown; and the old and still distinct *O. crispum* *Horsmani*, with flowers prettily spotted.

Messrs. JAS. VEITCH & SONS, Limited, Royal Exotic Nursery, King's Road, Chelsea, staged an interesting group, in which were their new hybrid *Phalaenopsis Stuartiana* Manni, staged with its parents, *P. Manni* and *P. Stuartiana*, or comparison. *P. Manni* is a botanical species with yellowish flowers barred with brown, and the hybrid showed great improvement upon it in size, and in form its sepals and petals being cream-yellow spotted with red, and their bases tinged with purple. The change in the lip of the hybrid showed *P. Stuartiana* only in the development of the side lobes, which are very inconspicuous in the seed-bearing parent. The blade of the lip showed no indication of the round apex of *P. Manni*. In colour it was cream-white tinged with brown (Award of Merit). Among the many-coloured variations of *Epidendrum* × *elegantulum* the firm showed *E. elegantulum leucochilum* in which the purple colour seen in the other forms is suppressed, the sepals and petals being pale yellow, and the lip pure white (Award of Merit). Another colour variation was *Dendrobium* × *Aspasia Langleyensis* (aureum × *Wardianum*), in which the reddish hue seen in other forms is wanting, and the whole flower is a clear yellow, the disc of the lip orange, and the base reddish-crimson (Award of Merit). Other remarkable plants were *Dendrobium splendidissimum nobilium* a very fine flower; *D. x Euryclea* (lituiflorum × *Wardianum*, a charming companion to *D. x micans*; *Epidendrum* × *Phoebeus* (O'Brienium × *vitellinum*), with brilliant scarlet flowers, equal to *E. radicans*, and showing the suppression or amalgamation of the petals, after the manner common in this class of hybrid, the flowers consisting of three outer segments, and a curved column, to which is attached the labellum; a showy hybrid *Laelio-Cattleya* (*C. Trianae* ♀ *L. purpurata* ♂), some fine plants of *Laelia* × *Latona*, *Laelio-Cattleya* × *Pallas*, *Dendrobium* × *Cybele*, *D. x Wiganiae*, *D. Rolfeae*, *Cymbidium* × *eburneo-Lowianum*, and the reverse cross *C. x Lowio-eburneum*; varieties of *Epidendrum* *Wallisii*, *E. x Endresio-Wallisii*, and *E. x elegantulum*, *Cattleya* × *intertexta*, *Laelio-Cattleya* × *Ascania*, *Laelia* × *Euterpe*, *Epiphronitis* × *Veitchi*, &c. (Silver Banksian Medal).

Major JOICEY, Sunningdale Park, Sunningdale (gr., Mr. Fred. J. Thorne), was awarded a Silver Banksian Medal for a group of a dozen grand plants of the fine white *Epidendrum* (c m) *icornutum*, with an aggregate of about forty heads of clear wax-like flowers—a triumph of cultural skill. Also in the group were the fine *Dendrobium atro-violaceum*, *Joicey's* variety, a fine specimen of *Cattleya Schroderae*, *Brassia Lewisii*, &c.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Aldous), showed the grand *Odontoglossum Wilckeanum* "Pitt's variety," an improvement on the one he previously exhibited, and which until now was thought to be the best extant. It bore very large flowers of fine form, the sepals clear yellow, tinged at the backs with red, and bearing on the face two or three very large red-brown blotches. The petals were fringed at the edge, clear yellow, with an ovate zone of red-brown blotches in the centre, and some few smaller spots at the base (First-class Certificate).

A. WARBURTON, Esq., Vine House, Haslingden (gr., Mr. T. Lofthouse), showed *Odontoglossum crispum Lindenii*, with clear white flowers, handsomely spotted with brown (Award of Merit); *O. Pescatorei* album, a pure white form, showing no other colour than the yellow callus on the lip; and a pretty *Cypripedium* of the *C. x Chas. Richman* class, said to be between *C. bellatulum* and *C. Fairieanum*.

Messrs. HUGH LOW & Co., Bush Hill Park, Middlesex, showed *Phalaenopsis* × *Schroderae* (leucorrhoda × *intermedia* *Portei*). The hybrid bore flowers of medium size, and was of a delicate blush-white, with the base of the lip marked red and yellow (Award of Merit).

R. I. MEASURES, Esq., Cambridge Lodge, Camberwell (gr., Mr. H. J. Chapman), staged a most interesting group, in which were two fine specimens of *Cymbidium Devonianum*, with several spikes each; *Cymbidium* × *eburneo-Lowianum*, and *C. x Lowio-eburneum*, several rare hybrid *Cypripediums*, *Dendrobium nobile* *Cooksoni* of the best type, and other *Dendrobiums*, good plants of *Cattleya Lawrenceana*, and among curious and pretty botanical plants the rare *Pleurothallis scapha*, *P. Grobyi*, and *P. ornata*.

Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), sent a grand inflorescence of *Coelogyne pandurata*.

J. BRADSHAW, Esq., The Grange, Southgate (gr., Mr. Whiffen), staged a neat group of excellently grown Orchids, among which were a noble form of *Cattleya labiata* Ludemanniana, some fine *Odontoglossum crispum* and other *Odontoglossums*, some handsome *Cattleya Trianaei* and *C. Mendeli*, *Oncidium olivaceum* Lawrenceanum, &c. (Silver Banksian Medal).

JEREMIAH COLEMAN, Esq., Gatton Park, Reigate (gr., Mr. King), had a very effective group, in the centre of which was a good example of *Coelogyne cristata* alba, and around it were plants of the handsome, richly-coloured form of *Odontoglossum ramosissimum*, *Dendrobium nobile nobilium*, and other fine forms of *D. nobile*, *D. Brymerianum*, a fine variety of *Sophranites grandiflora*, *Cymbidium* × *eburneolum*, *Dendrobium Victoria Regina*, a noble *Cattleya Trianaei*, &c. (Silver Banksian Medal).

JOHN MOSS, Esq., Wintershill, Bishops Waltham (gr., Mr. Kench), showed a fine form of *Odontoglossum Ruckerianum*, MALCOLM S. COOKE, Esq., Kingston Hill (gr., Mr. Buckell), sent a peculiar form of *Cypripedium Chamberlainianum*, and *Odontoglossum triumphans aureum*.

CLAUDE HAMILTON, Esq., Dunmore Park, Larbert, N.B., sent the fine *Dendrobium nobile*, Dunmore Park variety.

C. L. N. INGRAM, Esq., Elstead House, Godalming (gr., Mr. T. W. Bond), showed *Lælio-Cattleya* × *Sir William Ingram*, a very fine hybrid that was previously exhibited.

WALTER C. WALKER, Esq., Winchmore Hill (gr., Mr. Geo. Cragg), showed *Odontoglossum Andersonianum*, Walker's variety.

Narcissus Committee.

Present: Messrs J. T. Bennett-Poë, chairman; Messrs. Scrace Dickens, Jas. Walker, J. H. de Graaff, A. Kingsmill, Revs. G. H. Engleheart and C. MacMichael, Miss Willmott, and others.

Although the improved weather of the last few days has caused the Narcissi, hitherto pent up by the rainless cold of March, to come into bloom with a rush, yet there was but one large trade exhibit in the Drill Hall, which, it is almost superfluous to say, came from Messrs. Barr & Sons. The flowers, though perhaps not so large or substantial as in some seasons, were well-finished and coloured. Henry Irving and maximus in masses were very bright, while the scarcer trumpets, such as Weardale and Glory of Leyden, were a feature of this stand.

The Silver Cup offered by Messrs. Barr for the best collection of not less than forty varieties in the various sections was easily won by the Rev. G. H. ENGLEHEART, with his own flowers. J. W. JONES, Esq., was 2nd with a neat stage of bloom, in which the white trumpets were the best feature.

A good many new seedlings came before the committee, and awards were given as follows: To Messrs. BARR, Awards of Merit to Apricot, a small well-formed trumpet having the peculiarity of distinct apricot colour throughout the corona, and to a large trumpet in the way of Glory of Leyden. To the Rev. G. H. ENGLEHEART, first-class Certificates to Lady Margaret Boscawen, a very large and striking flower in the way of Sir Watkin, but with pure white segments of extraordinary width—this is quite one of the finest forms yet raised. To Poeticus Homer, a circular flower twice the size of ornatus, with a broad eye of deep red. To White Queen, a large broad-petalled flower with a Sir Watkin-like crown almost as white as the segments. Mr. ENGLEHEART also gained Awards of Merit for Oriflamme, a medium-sized variety of the short-cupped class, the perianth white, the entire cup fiery-red; and for Lucifer, perianth cream, crown long, of glowing orange-red.

Mr. Engleheart's large stand of his own seedlings was the centre of attraction in the hall, and comprised the above and many other forms not previously exhibited. The feature of the flowers was undoubtedly the greatly intensified depth of red colouring attained, and the new or much more decided range of colour in the hitherto rare tones known as salmon, apricot, citron, and the like. Torch, Southern Star, Flambeau, Flamingo, and many other brilliantly coloured flowers created much admiration, though the exhibit also included fine trumpets, hybrids of triandrus, pure white drooping flowers of the Leedsii class, and indeed most of the form and colour known in the Narcissus. This was probably the finest series of seedlings ever shown at one time by Mr. Engleheart.

Fruit Committee.

Present: Philip Crowley, Esq., Chairman; and Messrs. M. Gleeson, Jas. H. Veitch, A. F. Barron, J. Wright, Alex. Dean, J. W. Bates, C. Herrin, Geo. T. Miles, G. H. Sage, F. Q. Lane, J. Smith, G. Reynolds, G. Norman, J. Willard, and Robt. Fife.

Mr. J. F. McLeod, gr. to J. P. MORGAN, Esq., Dover House, Rochampton, exhibited three dozen splendid fruits of Brown Turkey Figs, ripe and large (Cultural Commendation).

A tray of Royal Sovereign Strawberries from Mr. E. BECKETT, gr., Aldenham House, Elstree, was also recommended a Cultural Commendation. The fruits were large, and each one in perfect state for table.

A third Cultural Commendation was recommended to Mr. Miller, gr. to Lord FOLEY, Ruxley Lodge, Esher, for a grand lot of Mushrooms.

Mr. C. Herrin, gr., Dropmore, won the premier place in the Apple competition with excellent examples of Sturmer Pippin, the produce of an aged standard tree.

Mr. J. J. HICKS, Hatton Garden, London, showed several novel thermometers, one of which is described as a new double self-recording Six's thermometer. This has been designed to enable the observer to compare any day's reading

with that of the previous day, and it is effected by leaving the tubes of sufficient length to permit of an additional scale with compressed division being placed above the other. Another novelty was Hicks' patent alarm thermometer. This differs from previous electrical thermometers in that by means of a magnet the index may be moved to any temperature desired—say 10° higher than the room is generally. Immediately the mercury reaches the index, a constant ringing of an electrical bell is commenced.

Lecture.

In the afternoon a most interesting lecture entitled "Blight and Blessing" was delivered by Mr. FRED. ENOCH, F.L.S. The discourse was very freely illustrated by means of excellent lantern slides, and explained minutely the life-history of some common garden insect pests, and of other insects parasitic or predatory upon same. As remarked afterwards by Professor Henslow, the facts Mr. Enoch so lucidly explained tended to show "the balance there is in nature."

Said the lecturer, there is probably no insect pest but has another insect that preys upon it, or is its parasite. Mr. Enoch further said that he believed it possible as did also the late Professor Riley, to increase the number of these parasites, which are helpful to the cultivator, inasmuch as they wage incessant war upon insects injurious to vegetation.

Mr. Enoch showed that this parasitism is carried on to the second and third degree—that is, that there are insects which are parasites upon parasites, and in such case the first parasite only is a friend to the cultivator, and the second one merely interferes, and in some measure prevents the good work of extermination he is engaged upon. One of the most familiar of the insects dealt with was the green aphid. This species is by no means without its enemies, for the maggot of the wasp-fly has been known to kill and suck them dry at the rate of 150 per hour. Its particular parasites are also responsible for the deaths of many more.

The Currant bud-mite was shown, and its extensive ravages alluded to. In connection with this pest Mr. Enoch has discovered a predaceous maggot that feeds upon the mite, and has obtained a perfect insect from the same. The slide represented this to be a very beautiful creature indeed. The Willow-sawfly and its parasites were beautifully shown and explained, and the Devil's Coach-horse also. The latter is very fond of the Cabbage caterpillar, and the antics whilst devouring the same were carefully explained.

R. McLachlan, Esq., who presided, in moving a vote of thanks to the lecturer, corroborated several of the facts given, and reiterated the lecturer's observations to the effect that it is extremely desirable that cultivators should acquire a better knowledge of insects, that they may distinguish between "Blights and Blessings," with a view to diminishing the former by preserving the latter.

ROYAL CALEDONIAN HORTICULTURAL.

APRIL 6, 7.—The Spring show was held on the above dates in the Waverley Market, Edinburgh. The following remarks are anent some of the principal features in the display.

HARDY PLANTS.

Hardy and forced plants made the major and more striking portions of the show. The hardy Rhododendrons and the hardy American and mollis-Azaleas of Messrs. LAMBOURN, DICKSON & Co. The groups of forced hardy plants such as Deutzias, Spiræas, Roses, Genista Scoparius, Andreanus, Cytisus albus, Kalmia latifolia, and Azaleas, drooped with freshness and glowed with colour. Even the premier prize for the best 12-feet table for effect, while owing much to Dendrobes, Liliums, Amaryllis, Cliveias, and Cyclamens, was greatly indebted to the magnificent specimens of Genistas Andreanus for its easy victory.

The same liberal use of hardy plants, forced or otherwise, formed characteristic features in the grand groups or tables furnished by leading nurserymen, such as Messrs. LAIRD, METHVEN & SONS, DOWNIE, and others.

The Silver Maples, as some of the variegated Acers are often called, the Japanese Maples, Brooms, Gueldeas Rose, Lilacs, hardy Azaleas were all used very liberally to produce artistic effect throughout the exhibition.

Messrs. BARR & SONS' great stand of Daffodils was very showy, as were the glowing Tulips and fine Hyacinths. And it is wise and well in these days of fever for Orchids, to pause occasionally and take note of the richness of beauty we possess in our hardy shrubs and trees when forced or naturally in season.

NEW GREENHOUSE RHODODENDRONS.

Two seedlings of Mr. McMILLAN'S, of Trinity Cottage, Edinburgh, were certificated at this show, of which Nathaniel Bryson, named in honour of the courteous energetic assistant-secretary of the society, is a fine pure white flower, with a soft pinky blotch, that is likely to have a popular and useful future, not only for its own special beauty, but through its power of breaking into different and brighter colours.

Beautiful and fragrant as most of these greenhouse Rhododendrons are, they are receiving too many white novelties. Not that we wish to get rid of white in this family—far from it; nevertheless scarlets, golds, pinks, cream-coloured, magentas, would be welcome in blotches, spots, or even as selfs. But the different species of Rhododendrons, such, for example, as *R. javanicum*, do not mix nicely with others. In Nathaniel Bryson, Mr. McMILLAN has given us a flower with a pink or blush blotch. The

other variety that received a First-class Certificate on this occasion, Mrs. McMillan, is a pure white, and specially fragrant.

On the evening before the show, April 5, the Scottish Horticultural Association held its monthly meeting in St. Andrew Square. There were several seedling greenhouse Rhododendrons then shown; and among others a pure white fragrant variety named Hercules, was awarded a First-class Certificate. Among other seedling Rhododendrons, the following were also promising white varieties:—Mr. Fitzwilliam, Miss Jessie Calder, White Queen.

ROSES IN POTS.

There were several exhibits of Roses in pots, which, however, left much room for improvement in regard to culture and setting-up. A few of the best varieties shown were The Bride, Francis Kruger, Caroline Kuster, Etoile de Lyon, Baroness Rothschild, Anne Clavier, Grace Darling, Maréchal Niel.

CUT ROSES

One of the most pleasing features in connection with the cut Roses, was the excellency of the four dozen Maréchal Niels. The following were the more notable blooms in the best stands of 24's and 12's: La France, Wm. Allan Richardson, Madame Hoste, Niphetos, Madame Lambard, Rêve d'Or, Duchess of Edinburgh, The Queen, Caroline Testout, and Caroline Kuster.

APPLES.

There was a capital collection of Apples, the whole of them appearing in sound condition. Among kitchen varieties we noticed fine examples of Gloria Mundi. According to the late Dr. Hogg, this fine Apple ought to have finished supplying us about Christmas, but here it was in good condition on April 6. The following also were shown in good sound condition:—Alfriston, Lane's Prince Albert, Newton Wonder, Bramley's Seedling, Hammond's Pearmain, Galloway Pippin, and Normanton Wonder and Wellington in two dishes. Dr. Hogg credits this last fine Apple with keeping till March; but here it was in good, though not in such condition as it was lately chronicled, promising to keep soundly until June.

That all too seldom seen Gooseberry-Apple was also well shown. One of the greatest merits of this valuable culinary apple is, that it comes into use in November, and continues sound and good till Apples come again. The greater the pity that more of it is not grown, and that anyone should begin using such a sure keeper before April. As this valuable late Apple is sometimes confounded with the much smaller and softer earlier Goose Apple, it may be well to give Dr. Hogg's description of the Gooseberry-Apple, to make sure of having it true:—"Fruit above medium size, roundish, with obtuse ribs on the sides, which extend to the crown, where they form ridges. Skin deep lively green, with a tinge of brownish-red next the sun. Eye open, not deeply sunk. Stamens medium, funnel-shaped. Stalk short. Flesh greenish-white, very tender, juicy, and with a fine, agreeable, and subdued acidity. Cells obovate; axils slit."

DESSERT APPLES.

We noticed the following varieties:—Kibston Pippin, Baumann's Red Reinette, Cornish Aromatic, King of the Pippins, Blenheim Orange, Reinette du Canada, Adams Pearmain, Cox's Orange Pippin, Dutch Mignonne, and Northern Spy. It is a pity that this last-named late Apple is not more grown in Scotland and the northern counties of England, where it might take the place of the scarlet and other Nonpareils, that seldom ripen of high quality in the North. The Northern Spy Apple is always distinguished by the highest flavour, the richest colour, and a Grape like bloom. Under careful storage and handling, it also keeps till mid-summer; and the longer it is kept, the deeper becomes its colour.

OTHER FRUITS.

Beyond Apples there was but little fruit exhibited. There were no Pears; but we noticed six bunches of Grapes, four of black, and one of Muscat—in no way notable for culture or keeping; two Pine apples, three dishes of Strawberries, and three collections of pots of Strawberries in fruit; and none was named. The only two bunches of white Grapes were Muscats.

BECKENHAM HORTICULTURAL.

THE members of the Beckenham Horticultural Society have, during the last three weeks, been enjoying a course of lectures on "Insects Injurious to Garden Crops," given by Mr. P. HEDWORTH FOULKE, B.Sc., Lecturer on Agricultural Entomology at the University Extension College, Reading.

Mr. FOULKE descended upon the various forms of insect-pests, and their differing modes of attacking plants, and the most approved methods both of prevention and cure. The lectures were rendered very interesting by the lime-light pictures with which they were illustrated. At the last meeting an extraordinary cluster of fine Mushrooms was shown by Mark Webster, gr. to E. J. PRESTON, Esq., of Kelsey Park.

CATALOGUES RECEIVED

THE YOKOHAMA NURSERY CO., LTD., Nos. 21-35, Nakamura, Yokohama, Japan—Lilies, Chrysanthemums, Camellias, Azaleas, Orchids, Maples, Magnolias, and Plants in general; Seeds, &c.

V. LEMOINE ET FILS, Rue du Moutet, Nancy, France.—Chrysanthemums, Begonias, Gladioli, Pelargoniums, Petunias, Fuchsias, and other plants

MARKETS.

COVENT GARDEN, APRIL 14.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

REMARKS.—On Saturday last, preceding the holidays, as is often the case, the vegetable trade was dull, prices lower, including Mushrooms and Rhubarb. On Tuesday the same state of things, and the few farm days brought Broccoli on rapidly. The recently-arrived Cape of Good Hope Grapes are not in fine condition. A consignment of Tasmanian Apples is due very shortly.

POTATOS.

Trade steady. Best samples a shade firmer. Current prices:—Maincrops, Saxons, and Bruce, 105s. to 120s.; Blacklands, 105s. to 115s.; Dunbar Maincrops, 130s. to 135s. per ton. Foreign Ware, 4s. 6d. to 5s. 3d. per bag. New Potatoes, 11s. to 22s. per cwt. John Bath, 32 and 34, Wellington Street, Covent Garden, W.C.

SEEDS.

LONDON: April 13.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., state that the late acceptable rains have naturally given some impetus to the sowing demand for Clover and Grass seeds, all descriptions of which are, however, still obtainable at temptingly low rates. For Tares, the enquiry is just now small. Rye is scarce, and wanted. There is no change in Peas, Haricots, or Lentils. Canary-seed is inactive. Hempseed is dearer. Full prices are asked for Mustard and Rapeseed. A small arrival is noted of new Scarlet Runners. Beans. Low rates continue to prevail for Canadian Wonder Beans. The Board of Trade Returns give the imports into the United Kingdom of Clover and grass seeds for the past three months as 172,614 cwt., value £337,171, as against 139,220 cwt., value £284,468 for the corresponding period of 1897.

NOTICES TO CORRESPONDENTS.

ARALIA: B. D. We cannot advise you unless we know the species.

BETTERIES IN CUCUMBER-HOUSE: Constant Reader. These beetles belong to the genus *Trox*. Their natural food is animal matter, such as bones, skins, &c., and in all probability they came to you in manure or fertiliser of some kind. They are not much likely to do any serious damage, unless it be to the manure. Set traps of dry rabbit-skins, bones, and such like, and destroy the beetles that collect under them. R. McL.

BOOKS: A. Hansen. The publication ceased to appear about fifteen years ago, and the volumes can now only be bought at the second-hand book-stalls.

CEDARS: Leaden. The sand that has accumulated round the boles should be cleared away, as well as the soil down to the roots; and in place of the latter make use of some half-decayed pasture-loam, mixed with well-rotted leaf-mould to the extent of a quarter of the whole bulk, or failing leaf-mould, rotten stable-manure in smaller proportion. This should be trodden firmly, and, where necessary, washed in among the roots with clean water. A mulch of tree-leaves 6 inches thick may be laid over the area occupied by the roots, keeping it in position with a thin covering of soil. Do not employ liquid-manure, as harm might be done. It might be worth while to discover the whereabouts of the extremities of the surface-roots, and afford these new soil in which to grow.

CENTAUREA CANDIDISSIMA, syn. C. Cineraria: F. F. The plants raised from autumn-sowings are, owing to various causes, seldom so good as those from early spring-sowings—probably the dry air, lack of ventilation, and need for frequent application of water, do not suit the plant; and your partial failure with the plant is due, probably, to some or all of these. Cold-frame treatment is best, and that can be safely afforded spring-raised plants.

DRAECENAS: R. T. The insect you send is one of the weevils, which are very destructive. Lay slices of Potato or Carrot on the stages to allure the weevils, and go round the house at night and catch them.

LILIES DISEASED: T. The flower-buds of *Lilium Harrisii* are attacked by a dangerous fungus-parasite of the "Botrytis" type, which was fully

described and illustrated by Professor Marshall Ward in *Annals of Botany*, vol. ii., 1888. A paper in the *Gardeners' Chronicle*, vol. iv., 1888, p. 184, probably refers to the same fungus, though under a different name. Professor Ward found the Lily-buds very badly damaged in a wet, moist summer. Probably your *Liliums* have been grown in a rather warm, moist atmosphere, with deficiency of ventilation. Plants as far gone as those sent us should be removed from beside healthy ones, and carefully burnt. Afford those left as much air as you possibly can; if they could be removed to another house, so much the better. We cannot confidently recommend any form of spraying, but experiments with a very dilute Bordeaux Mixture (see *Gardeners' Chronicle*, August 21, 1897) would do no harm, and might check the disease for the present; while, if applied before flowering next season, would probably prevent its appearance.

MOVEMENTS OF SAP: B. The fact is undoubted, but the explanation is incorrect or misleading. When it is said, for instance, that the sap at this season of the year flows with special force at and to the extremities of the branches, an impression is created that there is a channel through which the sap flows, and that there is a fluid of definite composition throughout the plant, which also is not the case. The budding of the young shoots at the extremities is due to the increasing heat and light to which the buds and growing points are subjected. It is in the bud that the activity of the protoplasm of the cells is most and earliest manifested. At the same time it is true that a supply of water is essential, and this is obtained by means of the roots. The growth does not begin below, but above.

MUSHROOM-BED: G. T. There is no necessity to cover a Mushroom-bed with litter unless the Mushroom-house is not fairly air-tight. With a brick or stone-built house furnished with a plaster ceiling, or with an arch thrown over, there is little evaporation of moisture from the beds at this season, no fire heat being employed to maintain the necessary temperature; moreover, the moisture thrown off by new beds not soiled over, and a slight sprinkling of the floor and walls suffice to prevent that aridity of the air that would extract moisture from the beds in bearing or coming on.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—W. G. B. 1, *Adiantum Cardiochlena*; 2, *Adiantum trapeziforme*; 3, *Adiantum taceum*; 4, *Davallia (Microlepia) platyphylla*; 5, *Croton Evansianum*; 6, probably *Croton irregularis*. These *Crotons* or *Codiaeums* vary so much in the foliage even of the same plant that it is difficult to name some of them accurately without seeing the plant.—W. A. Mint apparently, from the smell, specimen withered.—J. S. We cannot undertake to name florists' varieties of Indian Azaleas.—T. H. *Doronicum caucasicum*, *Cattleya Mendeli* variety.

RICHARDIA ETHIOPICA: C. A. The leaf you send has become partly white in place of green. What causes such occurrences we know not, but we see them on every hand, and they go to prove how nearly related flowers and spathes are to leaves.

SPIRÆA JAPONICA: Florist. There is no disease in the plant, and the injury is presumably due to some cultural detail. Is it possible that strong liquid-manure water has been spilled over the foliage? Or, are they too close to the heating-apparatus?

TOMATO DISEASE: A. B. The black spot caused by a fungus, *Cladosporium lycopersici*, often figured and described in these columns. Burn all affected plants, and spray the remainder with weak Bordeaux Mixture or with sulphide of potassium, half ounce to a gallon of water, taking care to avoid spraying the fruits which are approaching ripeness.

DIED.—On April 9, at Mena House Hotel, Pyramids, Egypt, aged 27, EUSTACE EDWARD, fourth son of Sir CHARLES WILLIAM STRICKLAND, Bart., of Hiltenley, Malton.

On the 11th inst., in London, on arrival from India, JEANIE A., wife of Sir GEORGE KING, K.C.I.E., F.R.S., late Superintendent Royal Botanic Gardens, Calcutta.

THE Gardeners' Chronicle.

SATURDAY, APRIL 23, 1898.

OSBECK'S "CHINA."

TO this country China has always been a territory of the greatest interest, sentimental as well as practical, for our own explorers—before and after Robert Fortune and Augustine Henry—have always been the most daring and the most successful. The Anglo-Chinese literature alone is sufficiently extensive to form a large library, and no inconsiderable portion of it relates to China's exceedingly rich flora, much of which yet remains to be fully explored.

Of the many interesting books on China which have been crowded into the background by the ever-flowing stream of fresh publications, there are few more entertaining than Peter Osbeck's account of his visit to China and the East Indies in 1750-51. Osbeck was rector of Hasloff and Woxtorp, in Sweden, an intimate friend of Linnæus, and a member of the Academy of Stockholm and of the Society of Upsal. His work was published on his return home in Swedish, thence it was turned into German by Godlich Georgi, under the eye of the author; from German it was translated into English by John Reinhold Forster, F.A.S., and published by Benjamin White, a relative of Gilbert White, of Selborne, in 1771, in two volumes. Osbeck had a passion for detail, and the natural history of every place the ship called at on the way out is detailed at some length.

The Chinese love of gardening and of flowers leads our traveller into several interesting particulars in his account of Canton. He noticed "several little trees in flower-pots before the windows, such as are likewise cultivated in their nurseries and gardens; *videlicet*, a sort of low sweet Orange-tree, with small fruits, which are called *namang* in China, and which are used instead of Tamarinds or common Lemons in punch, and generally before they are ripe." Among other plants he noticed *Narcissus tazetta*, or Chinese Lilies, which flower in January, and are called *Soisiun-fatt* by the Chinese; "their culture requires little art; they only put so much coarse sand upon a tin plate as just covers it, and upon this they set the bulbs quite naked. These were sooner in flower when the bulbs were prevented striking downwards." Other plants most noticeable were *Capsicum frutescens*, *Thuya orientalis*, *Nyctanthes orientalis*, *Celosia cristata*, *Gomphrena globosa*, *Impatiens balsamina*, and *Ipomoea Quamoclit*, in China called *Kam-fang-fang*, which adorned the hedges around about the city. Osbeck made a number of efforts to get some knowledge of the Chinese officinal herbs, and the diseases against which they are made use of, but although he "offered moderate rewards," he found this to be "utterly impossible."

As the Chinese live mostly on roots, fruits, and pot-herbs, it is, perhaps, not surprising that Osbeck found the country about Canton "almost all garden." Besides Rice, Sugar-canes, and Chinese Potatos, he noticed several kinds of Peas, and "two species of Beans, which are not usual in our country, for they require more warmth than our climate affords." One of these is *Dolichos sinensis*, which the Europeans call "Callvanses." The fruits mentioned included the Ling-Kamm, or Leng-ka (*Trapa natans*), "a fruit which looks like two horns put together, and has a kernel in the middle." Kamm-Katt, a sort of small Lemon, not much larger than a Cherry; Samm-nim, an oblong, yellow, sourish fruit, with five deep furrows, botanically known as *Averrhoa Bilimbi*, and which does not appear to have been introduced into England until forty years after Osbeck's visit; and two sorts of Orange, the Mandarin variety, "whose peel is quite loose," and the Kang variety, which is inferior to the other, and in which the peel "sits close." The other fruits and vegetables include the Mango, Tamarinds, Guayava, Gourds, Melons, Leeks, Radishes, Turnips, Carrots, Ginger, and Bamboo roots. The Chinese Potato, Fann-sio, or Fay-sio, the *Convolvulus batatas* of Linnæus, or *Convolvulus radice tuberosa esculenta minore purpurea* of Miller's *Dictionary*, a great novelty to Osbeck, is too generally known to require any description. Osbeck's comments on it are, however, curious: "these Potatos are quite different from ours, and seem to be natives of a warmer climate, for they never flower in China, so that they would hardly grow with us, though they are more palatable, and perhaps more wholesome than ours. They are planted in the dry sandy fields, at a distance from each other, manured with human dung, and kept clean from weeds;" a penny would purchase about 100 roots. Another root which served the purpose of Potatos is that of the Yam, in Chinese *Tdai-vio* (*Dioscorea alata*), it is planted like the Potato, on high places, about half a yard asunder, and a quarter of a yard deep; in winter it is kept in sand.

Osbeck made several botanical excursions, in several of which he fared badly at the hands of the natives; he gives a full account of the numerous plants which he saw or collected, among which was one subsequently named after him by Linnæus, *Osbeckia chinensis*, a pretty shrub which did not find its way into England until 1818. Osbeck gives a full-page plate of it, on which is inscribed its name in Chinese characters; it is figured in the *Botanical Magazine*, 4026. The whole plant is sold in the Chinese apothecaries' shops; they boil it together with old Kuli Tea, and drink the decoction in colics. Osbeck's other collections included *Rhamnus lineatus*, "a bush which till now has escaped the notice of botanists;" *Convallaria chinensis*, *foliis linearibus, corollis sex-partitis*, a medium between *Scilla* and *Convallaria*; *Ixora coccinea*, or Kang-long-sa, i.e., the Emperor's flower, which grows a yard high everywhere on the hills; *Barleria cristata*, *Mussaenda frondosa*, *Clerodendrum fortunatum*, another shrub that has "not yet been described by any botanist," *Lobelia zeylandica*, *Ruellia cristata*, and a large number of other flowering plants and Ferns.

We need not follow Osbeck on his return-voyage; his account of China and its interesting flora practically ends with the first volume. The second one is in part made up of his visits to Java and Ascension Island. This volume is of a very miscellaneous character, for

it includes a letter from Linnæus to Osbeck; a speech by the latter on his being chosen a member of the Royal Swedish Academy of Sciences, February 25, 1758, "showing what should be attended to in voyages to China;" a long account of a voyage to Suratte, China, &c., from April 1, 1750, to June 26, 1752, by Olof Toreen, in a series of letters to Linnæus; an exceedingly interesting "Account of the Chinese Husbandry," by Charles Gustave Ekeberg; and it concludes with a *Faunula sinensis* and *Flora sinensis*. This book, which contains a number of full-page plates of plants and Ferns, and is provided with an excellent index, is not only in itself a very early and important contribution to the scientific books relating to China, but is also an excellent book of travels in a country in which England, through the force of circumstances, is destined to play even a much larger part in the future than she has done in the past. *W. Roberts.*

NEW OR NOTEWORTHY PLANTS.

Among the "New Plants" shown at Ghent were the following:—

ACALYPHA GODSEFFIANA, Hort. Sander.*
(Fig. 87, p. 242.)

A LOW-GROWING shrub, of dense, bushy habit, with shortly-stalked, ovate or ovate-lanceolate leaves, slightly cordate, acuminate, coarsely-toothed, teeth incurved; disc $3\frac{1}{2}$ to 4 inches long, $2\frac{1}{4}$ to $2\frac{1}{2}$ inches wide, green, with a few thinly-scattered rather long white hairs on the upper surface and along the cream-coloured or whitish margins; petiole $\frac{3}{4}$ inch long, densely covered with felted seta. Flowers and fruit not seen. The cream-coloured marginal variegation gives this plant a very ornamental appearance. Although the flowers are not known, there can be little doubt as to the affinities of this plant, and, indeed, there is in the Kew herbarium a specimen which may be the green form of this species. This has been referred with doubt to *A. Pancheriana*, of Bailon, from which, however, it differs widely, as also from *A. obovata*, which has retuse, red-edged leaves. Our present plant, which will prove a very ornamental stove plant, was collected in New Guinea by Micholitz. *M. T. M.*

ACALYPHA SANDERI, N. E. Brown.†
(Fig. 93, p. 248.)

As this species has been already described in our columns, we need not enter into detail here, but merely note it as one of the most strikingly ornamental plants we have ever seen. Of branching habit, the branches spread widely, and throw down their long bright crimson spikes, like those of *Love Lies Bleeding* (12 to 18 inches long) beneath the broad ovate leaves in the most effective manner. To see a group of these plants at Messrs. Sander's, where one can look up at these crimson tassels, is to experience a sensation not to be forgotten. It was collected by Micholitz in the Bismarck Archipelago.

ALOCASIA WAVRINIANA, Hort. Sander.‡
(Fig. 89, p. 243.)

A stately species from Celebes, and differing from any other known to us in cultivation or in the her-

* *Acalypha Godseffiana*, Mast., ex. hort. Sander.—Frutex, foliis petiolatis ovatis vel ovato-lanceolatis cordatis, basi trinerviis, acuminatis serratis superne, nec non ad margines, setis longiusculis albidis dissitis munitis, disco viridi fascia latiuscula albida cineta. *M. T. M.*

† *Acalypha Sanderi*, N. E. Brown, in *Gardeners' Chronicle*, 1896, vol. xx., p. 392.

‡ *Alocasia Wavriniana*, Mast., sp. nov.—Foliis caspitosis erectis, petiolis 38 cent. long., purpureo-viridibus, flaventimaculatis, basi carnosius late dilatatis, superne canaliculatis arcte alatis; laminis circa 51 cent. long., 15 cent. lat., subcoriaceis, purpureo-viridibus glabris subtus cinereis basi truncatis, late lanceolatis acuminatis sinuato-lobatis, lobis latis obtusis apicem spectantibus, costa utrinque prominente; venis secundariis remotiusculis angulum cum costâ acutum efficientibus et in lobos marginales desinentibus; venis terciaribus inconspicuis crebris. Flores ignoti. Ex insul. Celebes in hort. Sander a cl. Micholitz introducta.

barium. The leaves form a dense erect tuft, each leaf stalked, lanceolate, glabrous, deep blackish-green-grey on the under surface. Petiole purplish, spotted with pale green, 15 inches (38 cent.) long, of the thickness of the thumb, much dilated at the base, above channelled and deeply winged; blade about 20 inches long (51 cent.), 6 inches wide (15 cent.), lanceolate acuminate, truncate at the base, deeply pinnately lobed, lobes bold, rounded, pointing towards the apex of the leaf; midrib prominent on both surfaces, secondary veins remote, coming off at an acute angle, and terminating in the marginal lobes; tertiary veins crowded, inconspicuous. The species is a native of Celebes, and was introduced to the Sanderian nursery by Mr. Micholitz. It has been named in compliment to the Comte de Wavrin. *M. T. M.*

FURCRAEA WATSONIANA SP., *Hort. Sander.*
(Fig. 90, p. 243.)

A beautiful and striking species, with leaves in tufts, each leaf spreading, as long as the arm, 2½ inches wide, convolute when young, undulate at the margin, and provided at distant intervals with minute spines. The disc of the leaf is bluish-green, with alternate bands of cream-coloured variegation.

PTYCHOSPERMA? *WARLETT.* (Fig. 91, p. 244.)

A Palm with silvery-grey stem more or less thickly covered with coarse blackish or purplish hairs. The foliage is pinnate, the segments oblong cuneate, rose at the margins, and silvery beneath. We do not give the dimensions as the plant is still young, and likely to develop in size and form as growth goes on. In the meantime it is very distinct, and highly decorative in character.

LEEA SAMBUCINA (= *L. ROEHRSIANA*, *hort. Sander.*)*
(Fig. 92, p. 245.)

A tropical climber, with pinnate foliage, 16 inches (40 cent.) long; each pinna is very shortly-stalked, 6½ inch (17 cent.) long, 2½ inches (6 cent.) wide, glaucescent, cordate, oblong, acuminate, coarsely crenate. The young leaves are bronzy-green, and the stem is marked with raised green spots.

This is a plant allied to *Cissus*, and found in the hotter parts of India, Malay Islands, Philippines, and tropical Australia. Not only has it this wide distribution, but it is exceedingly variable, and therefore plentifully endowed with synonyms, of which *L. Roehrsiana*, *hort. Sander*, is one. *M. T. M.*

PANAX? *MASTERSIANUM*, *Hort. Sander.*†
(Fig. 88.)

A stove foliage-plant of great beauty, elegance, and diversity in the foliage, combined with delicacy of coloration, and specially interesting as regards the form. The exact genus cannot be determined in the absence of flowers and fruit, so that the name above given is necessarily provisional. It is a shrub of scandent habit, with stalked, drooping, polymorphic, pinnate leaves about 3 feet (92 cent.) long. The petiole is thickened at the base, and, like the rachis, is greenish flushed with pink, and marked with linear white spots. After bearing four pairs of pinnae at remote intervals, the rachis suddenly bifurcates at an acute angle, one division of the rachis remaining straight and bearing three pairs of pinnae, the other straight below and above, flexuose in the middle, and bearing three alternate pinnae beneath, followed by a pair, one leaflet on either side of a terminal one. The

* *Leea sambucina*, Willdenow, Sp., Pl., i., 1177; *Rumph. Ambonina*, iv., 45; Lawson, in Hooker's *Flora of British India*, i. (1875), 666. *L. Roehrsiana*, *hort. Sander.*

† *Panax*? *Mastersianum*, *Hort. Sander.*—*Frutex scandens glabra; petiolis basi incrassatis roseo-viridibus, lineis albidis notatis; laminis magnis metralibus recurvis pedalis, polymorphis, oblongo lanceolatis remote (impari?) pinnatisectis, segmentis (circa 21) oppositis raro alternis, petiolulatis, petiolulis, 5 cent. long., supra medium articulatis, infra articulum subteretibus antice superne canaliculatis roseis; laminis glabris anguste lanceolatis acuminatis basi angustatis margine grossiuscule serratis serraturis subulato-spinulosis, nervo medio utrinque prominente roseo, venis secundariis arcuatis.* *M. T. Masters, ex hort. Sander.*

FIG. 87.—*ACALYPHA GODSEFFIANA*: *HORT. SANDER.* A SHRUB WITH GREEN LEAVES, EDGED WITH WHITE.
(Shown at Ghent as a New Plant. See p. 241.)

FIG. 88.—*PANAX MASTERSIANUM*: *HORT. SANDER.*

stalks of the leaflets or ultimate segments are $2\frac{1}{2}$ ins. (7 cent.) long, subangular, articulated at the upper third, dull reddish in colour. The blade of the leaflets is about 10 inches (25 cent.) long, $1\frac{1}{2}$ inch (4 cent.) wide, glabrous, pale green flushed with

foliage is specially conspicuous; and, doubtless, no two leaves will be found quite similar.

The plant is native of the Solomon Islands, from whence it was introduced to Messrs. Sanders' nursery by Mr. Micholitz. *M. T. M.*

FIG. 89.—*ALOCASIA WAVRINIANA*: MAST. EX. HORT. SANDER. LEAVES BRONZY-GREEN, MUCH REDUCED. (SEE P. 241.)

FIG. 90.—*FURCRAEA WATSONIANA*: HORT. SANDER. CREAM-COLOURED VARIEGATION, MUCH REDUCED. (SEE P. 242.)

pink, linear lanceolate acuminate, tapering at the base; midrib reddish, prominent on both surfaces, especially the lower; secondary venation arcuate; margins saw-toothed, each tooth with a small subulate spine. The description here given applies to the leaf before us, but this is a group in which diversity of form in the

PANDANUS SANDERI, Hort. Sander. (Fig. 94, Supplementary Illustration.)

This is a stove species of tufted habit, with long (30 in., 77 cent.), sword-shaped, variegated leaves, with minute marginal spines, not unlike those of *P. Veitchii*, but of denser habit, and differing much in the varie-

gation, which in this case is golden-yellow, and in place of being confined to the margin, or nearly so, it is distributed in narrow bands of yellow and green in alternation throughout the length of the leaf. It is a very showy stove shrub, and will be popular with gardeners from the brilliancy of its coloration. *Pandanus Veitchii* was first mentioned in Dallièr's *Plantes Ornamentales*, and afterwards in the *Gardeners' Chronicle*, 1868, p. 349, but little is known of the species; and the same remark applies to the beautiful form now before us. *M. T. M.*

RESTIO SPS., F. W. MOORE. (Fig. 96, p. 251.)

We ought to be familiar with the species of this genus, having recently monographed them in the *Flora Capensis*, and possibly because we do know something about the genus and its allies, we hesitate to identify the present plant, of which the sterile stem only is before us. It is of feathery habit, the very slender green branches being arranged in tufts springing from the axils of closely convolute mucronate sheaths. As will be seen, it is an ornamental plant, suitable for filling up gaps in the greenhouse stage, or possibly in the fernery; but as the species generally grow in dry places, too much moisture would be prejudicial. There are several species of highly decorative effect, so that it is remarkable that only one or two have been introduced, and these are not seen out of botanic gardens. *M. T. M.*

PINUS THUNBERGII AUREO-VARIEGATA.

This is a form in which the "needles" are transversely marked with alternating bands of green and yellow. Dr. Mayr, in his book on Japanese Abietines, mentions and figures other varieties of similar nature.

CERATOLOBUS MICHOLITZIANA. (Fig. 97, p. 251.)

A very elegant Palm, with the caudex and rachis provided with scattered spines thickened at the base. The leaves are oblong, the leaflets remote, linear-oblong, acute, paler on the under surface.

HOME CORRESPONDENCE.

SPECIES OF SEDUM AS CARPETING FOR FLOWER-BEDS.—Some time back, I recommended covering beds with an evergreen Sedum, a bit of which I enclose, and dotting bulbs singly about it. I have now carried this out on a large raised bed at Oakwood, using bulbs having blue flowers, such as *Chionodoxa gigantea*, *C. Luciliæ*, *C. Sardensis*, and different *Muscari*; this has been much admired, and is, I think, worthy of a note. I proposed trying another Sedum-bed with the best of the smaller and dwarfer species of *Narcissus*. Another quite different bed is now in beauty, a tree of Weeping Cherry (*Cerasus pendula*), now in full bloom, had thickly planted beneath it Primroses of many different colours; and the effect of the flowers above and below is, I think, good. *George F. Wilson, Heatherbank, Weybridge Heath.*

SPRING-FLOWERS AND SUNSHINE.—For many years I have observed that the amount of sunshine in each year, especially during the three spring months, is the measure of abundance or deficiency of spring-flowers in the next year, so that we know beforehand what to expect. Last year in this part of the country, the spring months were unusually sunny. The amount of bright sunshine in this district, which is not generally favoured with much sun, was greater than in any of the sixteen years during which records have been kept. In all the six districts into which England is divided for meteorological observation, the sunshine of 1897 was equal to or above the average of the last sixteen years, and for spring-flowers it was greatest at the right time. In this—the North Western district—it was fifteen per cent. above the average. Many spring-flowers depend upon the sunshine whilst the leaves of the year are maturing their growth; and those have flowered this spring with unusual abundance and vigour. Daffodils are an unfailing illustration of this; and Daffodils at Edge were never so fine as this spring, or had the number of flowers so great in proportion to the number of leaves. The variety *maximus*, the finest of the old Daffodils, which delights in hot sunshine, has surpassed itself. But a still more notable example of the effects of the sunshine of May and June on the following year is shown by the scarlet

Anemone hortensis. This is generally known to flower best the first spring after the importation of the roots from their sunny home in the south of France. After that they deteriorate more or less rapidly according to the seasons, and in this comparatively sunless district are often worn out in four or five years. But though it is now five years since my last importation, which consisted of a thousand roots, the sun of last year had such an effect upon them, that no newly-imported roots ever flowered so well as these have done this spring. They began early in January, and have been continuously blazing with flowers ever since, in spite of a little check during the wintry storms of March. Another plant which I have persevered in keeping for twenty years, though it has rarely given me any flowers, is the Algerian Iris unguicularis (syn. *stylosa*). This year it flowered for the first time abundantly through January and February. I could multiply examples, but those I have given are the most conspicuous of them. *C. Wolley Dod, Edge Hall, Malpas.*

"THE LOST ONION TRADE."—I have read Mr. C. Herrin's letter in a recent issue on this subject with great interest. It seems strange, and almost impossible that these French growers can sell so great a quantity of Onions retail amongst our own country folk to make it worth their while to come and stay so long here. It means that it is a large and growing undertaking. What would the French say to our putting a prohibitive duty on Onions? Only French-grown ones, of course. No Englishman dares (in the company of Englishmen), to suggest a duty on anything. Some few years since, the market for hot-house Grapes here got rather congested, and prices ruled very low. As we all know, an enormous growth has of late years taken place in the production of Grapes in the neighbourhood of London and Worthing. So Paris was tried, and with great success; a large trade at good prices began to develop, but no sooner did the few growers of hot-house Grapes in France find their trade being spoiled and prices lowered, than they petitioned their members of Parliament. The common-sense of Parliament was brought to bear on this important and national matter, and things were very soon put right—5s. per kil. (about 2 lb.) was put on as duty, which naturally completely stopped our share in that trade. Some things are better managed in France than in England, and it might help our Onion trade if we put a duty on French Onions, and kept it on until they take off the Grape-duty. *A Roland for an Oliver.*

BLIGHT AND BLESSING.—It would be a very great blessing indeed if some one would introduce me to a parasite or parasites that will check the ravages of the wireworm. Two years ago I took a piece of ground in the Bath Road, Hounslow, that was originally an Apple orchard, and for the space of four years had been untouched by the cultivator. It had become a dense mass of weeds, and when broken up a good deal of the rubbish on the surface had to be charred. The land is so infested with wireworm and destructive grubs, which destroy my Primrose and Polyanthus plants wholesale, and ruin Cauliflowers. It is said that the mole preys upon grubs, &c., but they do so much damage through their upheavals that I am driven to trapping the animals. If only some one would gain immortality by suggesting a sure method of destroying wireworms without injury to plant-life! I have, on the whole, a fertile soil, but the wireworms wreck certain crops, displaying in particular a great liking for the Primrose. There ought to be power to inflict a fine upon anyone who allows useful land to lie untilled and grow weeds, the seeds of which spread abroad, and infest the land of others in the neighbourhood, to their detriment. On taking possession I found the Apple-trees starved, badly cankered, affected with American-blight, and with the larvæ of various species of moths which affect Apple-trees in abundance. I had to cut away half of the branches of the trees in the endeavour to get the latter into a healthy condition. I would not be so much concerned were it not for the ravages of the wireworm. Will someone suggest a blessing in the way of a remedy. *R. Dean.*

DISEASED PINUS MONTICOLA.—Your correspondent, Wm. G. Smith, Yorkshire College, Leeds, in a recent issue of the *Gardeners' Chronicle*, has some interesting remarks on a dangerous disease of the Weymouth Pine. I send along with this note for your inspection some diseased branches of *Pinus monticola*, the cause of which I suppose to be the

dreaded rust (*Peridermium Strobi*), to which he refers, the symptoms are quite the same; only, strange to say, the Weymouth Pine is growing in close proximity to some large diseased trees of *P. monticola*, and is still quite free from attack. Unfortunately, it is spreading over all the *P. monticola* on the place, both old and young, and is getting very bad on some splendid trees over 60 feet high. The first time I noticed it was five years ago on a fine, healthy *P. monticola*, 10 feet high at about 1 foot from the ground beneath the first whorl of branches. The fungus was then (June) quite golden in colour, and when touched, it was scattered about like pollen. That tree was removed, but the disease has spread over a radius of 1000 yards. No species of *Ribes* is infected with it that I have seen, and no plants have been got from any nursery, all the young plants being raised from home-saved seed. I notice the young trees are

the whole bark is infested by the fungus-body, and so deeply imbedded that no curative agency can reach it. The Larch-canker has a somewhat similar mode of attack, and as yet no cure has been found except the clearing out of diseased specimens. The Larch is a tree of the Alps, and Larch-canker is well known to be worst on trees planted in low-lying, moist situations, while on higher ground it is less common. *Pinus monticola* is a native of the mountains of Northern California, and cannot be regarded as very hardy in Britain. May it not be that the trees are planted on the lower-lying grounds of Murthly, and thereby weakened in constitution, and rendered liable to this blister-rust?"

ALSTROEMERIAS.—Mr. E. Jenkins (p. 220) assumes too much when he says that "Mr. Ward does not appear to be aware that dozens of continental bulb-farmers, and also English growers of miscella-

FIG. 91.—PTYCHOSPERMA? WARLETI: HORT. SANDER. (SEE P. 242.)

usually affected on the bark low down, and the older trees on the points of the lower branches. The rust is also pinker in colour. If any of your numerous readers can suggest a remedy other than taking them out, all lovers of this fine Conifer would feel grateful. *James Laurie, The Gardens, Murthly Castle, Perth.* [Mr. W. G. Smith, of the Yorkshire College, Leeds, to whom we forwarded the branches of *Pinus monticola* sent by Mr. Laurie for inspection, remarks:—"The specimens of *Pinus monticola* forwarded are badly injured by the Pine-bark Blister-rust (*Peridermium pini*), and not by the Weymouth Pine-rust. In spite of a considerable amount of research, the life-history of this blister-rust is by no means cleared up; the Pine stage of the disease is very common, yet the stage corresponding to the *Ribes* stage of the Weymouth Pine-rust is still obscure. The swellings on the branches, with the copious exudation of turpentine-resin disfigure the Pines very much, and they cause withering up of the younger parts of the tree. Unfortunately, long ere the swellings appear

neous bulbous and tuberous-rooted plants have special methods in producing the right sort of saleable root, a matter only to be accomplished by, among other things, an annual lifting, a sorting, and a replanting of the group in question." Mr. Jenkins (by implication) includes himself among the specialists referred to above, as he informs the readers of the *Gardeners' Chronicle* in concluding his note that, "I (Mr. Jenkins) have grown many thousands of the best known kinds without the loss of any of them," adding, "of this quantity a goodly proportion was reserved for annual lifting, to supply customers," remarking that, "only those directly engaged in the work can form any idea of the superior character of the roots which this system and good tillage furnish." I beg to inform Mr. Jenkins that I am perfectly familiar with the above-mentioned practical details, as well as with the names and addresses (in which list I may now include his own) of special continental bulb-farmers, and also English growers of miscellaneous bulbous and tuberous-rooted plants, with a few

of whom I have had business transactions, and at the same time to remind him that an allusion to these facts in my original article (p. 156) was not in the least degree necessary. Mr. Jenkins, in reference to my recommendation of a space of 18 inches being allowed between the rows of *Alstroemerias*, and 1 foot between the patches of three or four seeds in the rows, says, "the same writer would cramp an already developed plant into a pot." And then he goes on to say, "Surely if the seeds of these *Alstroemerias* require so much freedom as 18 inches by 12 inches asunder in the rows, &c., a plant already past the seedling

of transplantation. As a rule, the plants do not remain long enough in the pots to become unduly pot-bound. Mr. Jenkins says, "So far as the hardiness of these plants is concerned, my experience coincides with that of Mr. Divers, that at 6 inches deep, the majority of the species are safe." And Mr. Divers says (p. 205), "four of the varieties named are quite hardy in our cold clay soil, having survived the severe winter of 1895-96 without injury and without protection;" adding "This was a sufficient test, the temperature on the ground being as low as 8° below zero. In view of these facts, readers of the

reasons for altering my original statement, "wherein all the reputedly hardy kinds [varieties] were unconditionally recommended for field culture." And all that has been written on the subject since has only served to bring a most beautiful and useful genus of plants prominently before the readers of this journal, and to furnish fuller details in regard to culture, but the original facts set forth at p. 156, hold good all the same, the somewhat hair-splitting statements of Mr. Jenkins to the contrary. At the same time, I fully admit that most subjects of practical horticulture are the better by being discussed in the columns of the *Gardeners' Chronicle*, and the readers as well as the writers benefit thereby. Criticism is a healthy thing, and I have not the slightest objection to writings of mine being criticised, the reverse being the case. *H. W. Ward, Rayleigh.* [Correspondence on this topic should now cease. Ed.]

NURSERY NOTES.

A NEW HARDY PLANT FARM.

HAVING known Mr. Amos Perry during his long connection with the firm of Ware, at Hale Farm, Tottenham, we felt an interest in visiting his newly-made hardy plant nursery at Winchmore Hill, to the north of London, one station nearer to King's Cross than is Enfield. Mr. Perry may be described as an enthusiast in regard to hardy plants; at any rate, he has an extensive and intimate knowledge of them. This he has been turning to account in a very practical manner since having embarked in business in his own name, and about 4 acres of ground at Winchmore Hill have been laid out in nursery beds, and more or less filled with an exceedingly choice collection of plants. It is a slope to the south-east, and at present lacks sufficient shelter from cold winds; but admitting the site as naturally a very cold one, Mr. Perry will be able to modify the conditions very considerably by planting suitable species of trees as "wind-breaks." In summer the other extreme is likely to occur, as the slope is exposed to much sunshine. The loam is yellow, and apparently very good, of considerable depth, and rests on a subsoil of clay. Under such circumstances it was not surprising that there were yet few species of plants in flower [April 4], for the month of March was unkind, commencing fairly warm, and growing less and less warm until the weather at its close was blizzard and frost.

In the absence of masses of flower, therefore, our time was occupied in looking through the collections of the rarer plants, and chatting upon the system most suitable to the partial protection of some of the less hardy species during winter and spring. We do not intend to go deeply into such matters here, but in one case it may be interesting to give Mr. Perry's very simple, and (so far as it has been tested) effective practice. The *Tritomas*, and especially some of the yellow-flowered varieties, are easily injured by severe frost or cutting winds. Mr. Perry has a collection of about thirty varieties; the plants are in narrow nursery beds, and on either side of each bed has been planted a stout row of a tall-growing perennial *Aster*, the tops of which are left uncut until cold winds in spring have ceased, by which time the new *Aster* growths are pushing apace. These are capital wind-breaks, and in addition to this the plants have loosely strewn over them the flowering stems of *Asters* cut down in the winter, which serve to protect the plants from frost. All of the *Tritomas* look capital, and will be sure to flower finely, but it must be granted that the winter just passed has not been a severe one. In the cold midland counties we used to liberally mulch the *Tritomas* with manure each autumn, and by the exercise of a little care very few of the plants suffered injury. The double-flowered *Hollyhocks*, of which Mr. Perry says he has about forty distinct coloured varieties, were hardly through the ground. Primroses in numerous strains were aglow with flowers, and one of these, with plum-coloured flowers, had quite a novel tint. That early and fragrant *Wallflower*, Harpur Crewe, with its profusely-leaved numerous branches, was blooming freely, but the older yellow-flowered sorts were yet in bud. Close to this was noticed an exceeding dwarf

FIG. 92.—*LEEA SAMBUCINA* (VAR. *ROEHRSIANA*, HORT. SANDER). MUCH REDUCED.

(SEE P. 242.)

stage cannot be benefited by being confined in the small pots usually adopted by the trade." Mr. Jenkins, in writing thus, seems to be unmindful of the facts involved therein, namely, that the seeds and the plants resulting therefrom are afforded the spaces indicated, in order to admit of the plants developing themselves to large and profitable dimensions for several years to come—in short, they are put into the ground to remain there undisturbed for a series of years by the flower-farmer, while the reverse is the case with tiny plants potted-up by the trade in the autumn, or resulting from seed sown in small pots, so as to enable customers to make plantations of this most serviceable and beautiful class of plants without subjecting them to a check in the process

Gardeners' Chronicle may look forward in the near future to seeing Mr. Jenkins record the fact of all species of *Alstroemeria* planted 3 or 4 inches deep in light soil of "average-depth and fertility," being quite safe (this being the description of soil that I recommended the said plants being set in). I think most practical men will allow, that any plants planted at 6 inches deep in a cold clay soil, which survive in a temperature of 8° below zero (40° frost), without injury and without protection, are capable of surviving in a like temperature when planted only 3 or 4 inches deep in "light soil of average depth and fertility, and, if possible, in situations which are sheltered from the north and east winds." In conclusion, I cannot admit of any

Iberis, "Little Gem," that is said never to be more than 3 inches in height; its flower-buds were about to burst. There were very large beds of the bright orange-flowered Geum Heldreichii, which we were informed represented an unusually good variety. Most of the Lilies grow exceedingly well here, and a very representative collection already exists. The same may be said of Perennial Asters, Paeonies, and Eremurus. Amongst the flowering plants, we noticed Pentstemon Menziesii, a trim-looking evergreen shrub, about a foot high; it will later produce gentian-blue coloured flowers. Aquilegias do well, and especially the very fine one known as A. Stuarti, a deep rich blue flowered plant with white corolla. Among the Fritillarias was the pretty F. pluriflora in bloom; the flowers are light rosy-purple in colour, with radiated purple base, and were figured in *Gardeners' Chronicle*, April 10, 1896, p. 231. In a raised and partially-sheltered bed was a collection of Erythroniums, including a fine lot of the Californian species, of which perhaps the best is E. Johnsoni. Soldanella alpina was blooming very freely in 3-inch pots, and looked extremely pretty. In one of the borders was a moderate sized plant of Hcdysarum multijugum just commencing to show signs of growth; and Veronica Hecatori, a New Zealand species, looking like a giant moss or miniature Conifer. Heuchera sanguinea in batches looked capital, and Mr. Perry says he has an uncommonly good variety of this splendid plant. The white-flowered Heuchera does not promise great things at present, and is hardly likely when better known to prove so valuable a plant as H. sanguinea. Perovskia atriplicifolia has passed through the winter safely; at present it is nearly bare of leaves. The foliage when produced later in the season will be silvery, and the flowers are blue, but it is a very rare plant in this country.

BELGIUM.

PHŒNICOPHORUM SEHELLARUM.

At the Horticulture Internationale, at Brussels, is to be seen now a considerable number of this grand tropical Palm. Coming from the tropics, it needs a high temperature to grow it successfully. It is not safe to let the temperature of the house fall often below 60° during the winter season, in fact, 60° should be the minimum at any time; the other point to observe is not to allow any cold drips to fall upon the leaves from the roof. Given these two conditions, and that of an abundance of water, it will be one of the finest possible features in any stove-house of sufficient dimensions. As an example of what an amount of water it will stand, I might quote as an instance, that of the large plant in question, which from force of circumstances became too tall for the house, and had to be sunk into the central tank of warm water. It stood the treatment well, and even thrived upon it. It is a pity such a grand tropical plant as this should be so seldom seen in English gardens. H.

TREE FERNS IN THE BOTANIC GARDENS, BRUSSELS.

Several well-developed specimens are to be seen here, being evidently in quite congenial quarters. The examples of Cibotium princeps are of remarkable dimensions, and owing to the absence of overcrowding, are developed in a perfect manner; C. Schedei is also in good form here. There is likewise a large plant of Cyathea medularis, which, standing as it does, near to C. princeps, affords a remarkable contrast as the stems of one are of a pale fawn-colour, and the other (the Cyathea) nearly or quite black. Of the Cibotium, there is a remarkably tall plant, fully 30 feet in height, with a slender stem, which does not really appear strong enough to support the canopy of fronds at the summit. The Marattias are also grown well in this lofty house. H.

THE GROUPING OF PALMS.

Good illustrations of the best methods of displaying specimen Palms and other fine-foliage plants may be seen in several of the continental nurseries.

A favourite plan is to raise the best specimens upon pedestals sufficiently high to walk under them with advantage and comfort. In this way seats can be arranged with convenience, and the utmost possible use can be made of the ground space. Another method is to completely cover the end walls of span-roofed houses with rock-work, and then by judicious planting to cover it as soon as possible. If there be sufficient room at the base, a convenient spot is found for a well-developed specimen Palm or Tree-Fern, under which a ground-work or carpeting is arranged, care being taken not to overcrowd the individual specimens. H.

FRUIT REGISTER.

PEAR TRIOMPHE DE VIENNE.

A FINE looking fruit, in form and length of stalk near resembling Jargonelle, with a rind varying from greenish-yellow and light yellow to a tender carmine-red tint on the sunny-side, and covered with russet patches as to impart roughness to the touch. The flesh is whitish, and just beneath the rind yellowish, melting, juicy, pleasantly sweet, spicy, and good flavoured. The core is small, and the seeds blackish, but usually imperfect. Ripe the middle of September, and in unfavourable districts at the end of that month, and the beginning of October. The tree grows with vigour on Wilding or Quince stocks, and takes naturally the pyramidal habit. The variety was raised by M. Jean Colland, a gardener at Vienne, Département de l'Isère; and was first distributed by MM. Blanchet and Morel, nurserymen, at the same place, and at Vaise-Lyon in 1874. We notice the variety in Messrs. T. Rivers & Son's catalogue for 1897 and 1898, among select Pears, but it is absent from the revised R. Hogg's *Fruit Manual*. A coloured illustration of the fruit is given in the *Gartenflora*, April 15, 1898.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By J. W. MCHATTIE, Gardener, Strathfieldsaye, Hants.

The Management and Sowing of Peas.—The weather being dry in the south, water must be afforded to transplanted Peas in the open, and crops of Peas growing in pits, &c., and protection likewise on nights when frost appears likely, and also on cold days. When Pea-plants appear, lightly mould them up, and then sprinkle them with fresh soot or dry lime. Do not use Pea sticks with blunt ends, or the roots may get injured, but give each a sharp point, and place small twigs on either side of the rows, and thus maintain the plants erect. These twigs, as also the Pea-sticks proper, should not meet at the top. Peas for the main crops may now be sown in trenched but not necessarily highly manured soil, and the following varieties will be found of superior flavour and very productive, G. F. Wilson, height 4 feet; Sutton's Magnum Bonum, height 4 feet; Ne Plus Ultra, height 5 feet; and Reading Giant, height 6 feet. The above varieties are wrinkled Marrowfat Peas. Varieties for present sowing of lesser height are Renown (new), Windsor Castle, McLean's Best of All, and Walker's Perpetual Bearer.

Cauliflowers.—Take advantage of showery weather to transplant Cauliflowers, putting some of the plants on a warm border, and for small growers like Early Forcing, at a distance of 1 foot apart. As a protection against cold, place a 6-inch flower-pot over each plant at night, or employ evergreen twigs for that purpose. Plants raised from seed sown in March ought to be fit for pricking-out in nurse-beds, or if weak, then on to a mild hotbed, but do not coddle them with top-heat or much use of glass or thick coverings at night.

Forced Vegetables.—Sowings of French or Kidney Beans should still be made at regular intervals of time in pots or on hotbeds. Water will be required in abundance by plants in bearing, and the syringe to be freely used twice a day. The frames and pits vacated by the early Potatoes may be utilised for raising French Beans, sowing Williams' Early Forcing and Veitch's Early Favourite, whose pods will be ready for gathering in from six to eight weeks from

the time of sowing. Gather the shoots of *Seakale* as soon as it is large enough, as this vegetable toughens if left long in darkness; make up Mushroom-beds and afford water at 80° to beds that are in need of moisture, and let the Mushroom-house be damped-down mornings and evenings, and the temperature kept at 60°.

General Hints.—Examine beds and lines of all kinds of roots, and where entire or partial failure has taken place, re-sow the land without delay, or sow in another place, as may be deemed best. Thin the rows of Spinach, mould-up Broad Beans, wage constant war against weeds, and keep the soil stirred by hand-fork, hoe, or other tool among crops of all sorts.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Carnations.—Those plants which have been wintered in pots in cold frames, will have been in most parts of the country planted out some time ago, as was advised by me in an earlier calendar. During dry weather these plants will stand in need of water occasionally in order to prevent their flagging, and to assist root action. Those layers and seedlings which were planted in the autumn of last year, will in most cases have made good progress; and to assist growth, the soil between the plants should be stirred with the hoe, and about the end of the month they should receive a top-dressing of well-rotted Mushroom-bed manure, wood-ashes and fresh soot, the whole of these matters being mixed together and run through a coarse sieve. This dressing should be laid on evenly, about one inch thick. The increase of vigour in the plants will soon make it apparent that they are deriving benefit from the dressing, assuming that the plants were in a healthy state. Each plant should be provided with a neat stake in readiness for securing the flower-spikes thereto, some of which are already well advanced. A common mistake made by Carnation-growers in the south of England, and the cause of a great many failures, is the coddling of the plants in the winter, and neglecting to treat them as hardy subjects. If layers are plentifully furnished with roots early in August or the beginning of September, and are then planted, there is no fear about the plant's surviving the winter. But it is different when the layers are taken off when one or two little roots about one-eighth of an inch long are apparent, for then they may succumb to the perils of even a mild winter. Carnations cannot have too much sun; moreover, they should not be planted in confined places, else a good deal of damping will occur among the plants during the winter. If seed was sown early in the month of March this year, the seedlings should now be fit for placing in 3 inch pots. The potting should be done firmly, and the soil used a fairly-rich sandy loam, and the pots well drained; keep them for a few days in a temperature of 55°, and gradually harden off, preparatory to planting them in the open in May and June.

General Remarks.—Work in the flower-garden is now abundant, for the lawns will need often mowing; weeds must be hoed up in beds and borders, or hand-weeding resorted to if the surface cannot be hoed; also weeds on walks must be got rid of, and the surest way to do this is to dress the gravel with one of the many weed-killers on the market, taking great care to keep the weed-killer from injuring the turf or box-edgings, &c. Continue to box off and prick out bedding plants, half-hardy annuals, &c., as fast as the plants get large enough, never permitting them to spoil by being crowded. Continue the potting of seedling Dahlias and those raised from cuttings, and afford the bedding Pelargoniums abundance of air and plenty of water whenever it is necessary to afford the latter.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Dendrobiums.—The following species of *Dendrobium*, viz., D. thyrsiflorum, D. densiflorum, D. Farmeri, D. Schroderae, D. Griffithianum, D. Guibertianum, D. fimbriatum, D. chrysotoxum, D. suavisimum, D. Dalhousieanum, D. moschatum, D. calceolus, D. clavatum, all of which flower in racemes, and whose flower-buds are now getting prominent, should be afforded a greater quantity of water at the roots, and a slightly warmer temperature, in order to encourage the development of the racemes. If these species are to flower in the months of May and June, they should, however, still be kept rather dry at the root and cool, and afforded just as much moisture as will keep the pseudo-bulbs somewhat plump.

Androbium cymbidioides, now growing freely, may be repotted, if this be necessary, before root-growth begins, and the plant should be suspended to the roof of the Cattleya-house. The rare *D. Treacherianum* requires the warmth of the stove, and being at rest at this date, it requires but little root-moisture; but as soon as the growths begin to advance, abundance of water becomes necessary. *D. Cologyne* is not a compact grower, for each new growth extends the length of the plant from 6 to 8 inches; a pot or an in which to grow the plant is therefore useless, and a long teak basket answers the purpose better. Let the plant be hung up to the roof of the intermediate-house, and when growth begins, afford it generous treatment. As the plant revels in sphagnum-moss growing luxuriantly around the base of the pseudo-bulbs and under the rhizomes, the old dead moss should be removed, and living substituted for it, rickling it in all over the surface. *D. scabrilingue*, better known as *D. hedyosmum*, is now in bloom, and appears to thrive best when suspended to the roof of the intermediate-house.

Miltonias.—In the same temperature plants of *Miltonia Phaenopsis* will be in full growth. Unfortunately, this is a plant seldom seen in fine health, owing to its liability to attack from a species of red-spider (*acarus*). The best means to clear off these pests is to dip the foliage two or three times a day during bright sunshine into tepid water. The flower-pike should be removed from sickly plants, and the plants be divided into small pieces and repotted in well-drained pots, using as potting material sphagnum-moss only. *Miltonia Roezlii* is another rather difficult species to keep in good health, and it succeeds best at the warm end of the intermediate-house; and, being a plant whose roots keep close at home, it should not be overpotted, and the roots are the stronger when they seize firmly on to the inside surface of the pot, and when that occurs the plant may then be afforded abundance of water at all times. As a small species of yellow Thrips are apt to infest the young leaves, it is advisable, when using the XL All vaporiser in a house to place these plants therein.

Catasetums, *Cynoches*, and *Mormodes*, very fine subjects when in flower, as well as curious and interesting plants, are on the move, and should therefore have early attention, shaking them out of the old compost, cutting off dead and decayed parts, carefully examining the pseudo-bulbs for mealy-bug and scale, especially at the base, for if they are not thoroughly cleared of these insects before repotting, they will be troublesome throughout the season. *Mormodes* and *Cynoches* will grow satisfactorily in well-drained pots or shallow pans, but shallow teak baskets are best for *Catasetums*. For the stronger-growing species a mixture of equal parts of peat and sphagnum-moss may be employed; while for those of weak growth chopped sphagnum-moss, mixed with a moderate quantity of small crocks, is all that is needed. The *Mormodes* do best in the Cattleya-house, and the other species delight in strong heat and a clear light at all times. For the next few weeks water must be afforded sparingly, and when the new roots have run through the compost let it be abundant. To keep these plants in good health for years, they must be afforded a generous growing treatment at the first, and afterwards a thorough ripening, followed by a long decided rest.

Eulophia Guineensis, a rare and beautiful Orchid when well grown, produces strong spikes of large rose-lipped flowers, which last for several weeks in good condition, and the plant, having now begun to grow, should be repotted. A compost consisting of fibry loam, peat, and leaf-soil in equal parts, some chopped sphagnum moss, small crocks, and coarse silver-sand, the whole being well mixed together, will suit its requirements. Let the plant be suspended to the roof of the warmest house, affording it plenty of sunlight without exposure to strong sunshine. After repotting, let no water be afforded before new roots are seen to be pushing towards the sides of the pot. When growing vigorously, it will take as much water as the deciduous *Calanthes*.

HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Strawberries.—As the early varieties will soon begin to flower, provision must be made for mulching the ground; and, if slugs abound, these should be trapped without delay by laying 1-inch-thick slices of Swede-Turnip about the beds, examining the latter early every morning for the slugs, which will be found on the under-side, to which they retreat soon after daybreak. They may be scraped into a vessel, and killed with fresh quicklime or

boiling-water. If this method be persevered with during mild, damp weather, for a few weeks, thousands may be caught, and much damage to the fruit prevented. I have tried other roots, such as Parsnips, Carrots, and Mangolds, for this purpose, but Swedes have proved by far the most attractive bait. Woodlice are sometimes troublesome, and are best dealt with by inverting flower-pots filled with dry moss or soft hay in the rows. Mice are the most destructive pests, causing serious damage by gnawing the seeds from the fruits when ripening, and they are very difficult to catch, not readily taking any kind of bait when Strawberries are plentiful; and they should be trapped forthwith in all parts of the garden. The rainfall during the present season has been generally very much below the average, and unless abundant rains fall soon, the Strawberry-beds should be afforded a good soaking of liquid-manure, and also one of clear water, before the mulching is put on the land. The application of water may need to be repeated afterwards at intervals, till the first fruits are half-grown. In light soils, water at the roots is especially necessary, if large and well-flavoured fruits are to be obtained. All small weeds should be destroyed in the beds with the Dutch-hoe before the mulching is put on, or they will grow up through it, and prove very troublesome when the fruit is ripening; especially if the weather be showery, and nothing in the way of weeding can be done at that time. The best material for a mulching is long, fresh stable-litter, shaken free of all droppings and short straw, and this should be carefully packed around the collar of each plant, and made to cover all the ground between the plants; if it be put on before the flowers expand, the rains, or the water afforded, will wash it clean and sweet before the fruits ripen. The worst mulching consists of lawn-mowings; but as these are short and clean, it is not so important to put this kind of mulch on the ground so early. Lawn-mowings harbour slugs and other insects, and become a slimy, slippery mass in wet seasons. If they can be dried—that is, made into hay by a few days' exposure in the sun—the mulch is not quite so bad.

Nets.—The stock of nets should be examined, and new ones ordered betimes to replace those that are worn out. Fruit-nets are best made with a square meshes, and of a size 8 feet wider than the beds, so that they can be elevated 4 feet above the surface of the ground, and thus allow space for a man to go beneath them when gathering the fruit, without the trouble and loss of time involved in taking them off the plantation.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Temporary Shelter.—The lack of space in glass-houses is an ever present difficulty at this season, and as each batch of plants is potted up, the question arises, where shall they be placed? and often they have perforce to go in unsuitable positions. Something may be done to ease the pressure, by making rough frames in some warm position with spare lights and boards, straw-hurdles, &c., which answer for a short time; failing these, frames may be made of laths and roofing-battens, so that mats, canvas, Frigidom, and the like can be used to protect the more forward or the hardier plants at a moment's notice. Oiled canvas nailed on light frames is a capital protector, and does not need removal during the hours of daylight. Spring weather is proverbially fickle, and every precaution must be taken to guard plants from injury by frost, hail, &c.

Propagation of Plants.—Cuttings of *Panicum*, *Tradescantia*, and *Selaginella*, may be taken and struck in heat; *Isolepis gracilis*, or any old plants of *Carex japonica*, and *C. j. variegata*, may now be split up and repotted.

Miscellaneous Matters.—Shading must be carefully attended to, or a sudden burst of sunshine after a dull period may do a lot of harm to tender foliage plants. Some of the *Caladiums* are particularly tender in this respect, and exposure to sudden bursts of bright sunshine will spoil their appearance for the rest of the year. Plants of *Bougainvillea glabra* trained on the roof of warm houses, should have a large portion of the shoots which emerge from the main stems, thinned severely, or a crowded mass of growths, with but little flower on them, will result. Stake and tie-out the shoots of *Pelargoniums* before they become drawn, and afford the plants plenty of air when the weather is favourable. Those plants which have filled their flowering-pots with roots may be afforded weak farmyard manure-water, varied with spot-

water. *Lapagerias*, if now in free growth, will need water in abundance at the roots, and if in small borders, weak manure-water should be applied alternately with clean water. Do not allow the shoots to touch the glass or twist round the wires, but tie them in loosely, drawing them from beneath the wires, so as to cause them to droop, which is best for showing off the flowers. The house in which *Lapageria* is grown should be kept cool and well ventilated.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Grape Vines.—The little plants which have been raised from "eyes" this season having filled with roots the 6-inch pots into which they were transferred from 60's their first pots, should be shifted into 8-inch pots before they get pot-bound. "Cut backs" of one year old intended for fruiting in 1899, which were shaken out, repotted in 8-inch pots, and started in the manner recommended in an earlier article, when ready for repotting may go into the fruiting-pots, that is, 11-inch ones, which may be new, or merely old pots washed clean; if new, they should be laid in water some hours previously. The drainage of these pots should consist of clean crocks laid in 2 inches deep for 8-inch, and 2½ for 11-inch pots, the placing of the pieces being carefully performed. As the drainage in the 11-inch pots requires to be effective for two seasons, only crocks of pieces 2 to 3 inches broad should be used, and these with the hollow side downwards; and one strong piece over the hole or holes, and a thin layer of loam, fibre, or moss over all. The best sort of soil is a somewhat light turfy-loam, pulled in such pieces as will go down between the pots and the ball without injury to the roots, a peck of old mortar-rubble, and a 7-inch potful of bone-meal to each wheelbarrow load of loam, the whole being mixed and made warm before use. It should be in a moderately moist state. The first layer of soil over the drainage may be made firm and close with a potting-stick, and on this the roots should be spread that may have grown amongst the drainage of the earlier pot, then put the soil round the ball in three or four layers, ramming it each time, so that it is equally firm throughout, and finally leave a 2 inch space for water. Afford the plants sufficient water to moisten the whole mass of the soil, and shade them from bright sun in a rather close house for a few days. Do not be too free with the use of water before activity in the roots has greatly increased, and never afford any without first rapping the pots, when if a hollow sound is given forth, water is required. When Vines often require water, it is an indication that the roots are absorbing it largely, and progressing. See that the leading shoot is secured against injury, and stop the earliest side-shoots at the first joint, rubbing off the secondary shoots that spring from them. These Vines should be syringed twice on very sunny days, that is, early in the morning, and at closing time; at other times growing conditions may be secured by damping down. In order to grow strong, short-jointed, firm wood, plenty of light, heat, and a free ventilation are essential. See *Gardeners' Chronicle* for March 5.

Strawberries.—Fruiting plants, particularly those with forward fruits, will require water twice on fine days, and the syringe to be used on the foliage freely morning and afternoon after the berries are set. Successional plants may be brought into heat from the forwarding pits in order to maintain a regular supply of fruit, and this must be done till Strawberries are ripe out of doors. Should there still be plants left out-of-doors, they should be taken care of and protection afforded when the flowers appear. These late plants are valuable if the out-of-door's crop is late. The best Strawberry runners for growing into plants for forcing next year are those that spring from young plants planted-out last autumn. The truss of flower should be pinched off these before the flowers begin to open, so as to throw the strength of the plant into the runners. A mulching of decayed manure put on now will add to the vigour of the plants. In dry weather, afford a copious watering occasionally, to prevent them suffering. Strawberries under glass are subject to the attack of mildew; and the most likely time is after the fruit is set. A good remedy for it is to mix half-a-pint of sulphur into a paste, and add it to 2 gallons of water, and after stirring it well, it should be sprayed on to the foliage and fruit with a spraying-syringe, and ordinary syringing should be discontinued for a few days. Should fruit be ripening, when mildew shows itself, paint the hot-water-pipes with sulphur and whiting, and keep a little more warmth in the pipes for a few days, when the mildew will be checked.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, APRIL 26 { Royal Horticultural Society's Committees, at the Drill Hall, James Street, Westminster; and Lecture on "Sweet-scented Leaves versus Fragrant Flowers," by Mr. F. W. Burbidge, M.A., V.M.H., at 3 P.M. National Auricula and Primula Society, S. Section, at the Drill Hall, James Street, Westminster.

SALES.

TUESDAY, APRIL 26 { Hardy Perennials, Roses, Border Plants, Carnations, &c., at Protheroe & Morris' Rooms.

WEDNESDAY, APRIL 27 { Japanese Lilies, Palm Seeds, Begonias, Dahlias, &c., at Protheroe & Morris' Rooms.

THURSDAY, APRIL 28 { Border Plants, Bulbs, Lilies, Palms, &c., at Stevens' Rooms.

FRIDAY, APRIL 29 { Hardy Perennials, Roses, Border Plants, Carnations, &c., at Protheroe & Morris' Rooms.

Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—49° 8'.

ACTUAL TEMPERATURES:—

LONDON.—April 20 (6 P.M.): Max., 61°; Min., 43°.

PROVINCES.—April 20 (6 P.M.): Max., 58°, York; Min., 48°, Aberdeen.

ONCE again the quinquennial fever has visited the city of Ghent. The quaint old place, ordinarily so quiet, is given up to visitors from almost all the countries of Europe, who make it obvious that it will be a long while yet ere we get a universal language, and yet how strong is the link which the Belgians, utilising the common love of flowers, have forged. It is easy to say that the bond between themselves and their visitors is a commercial one. Even if it be so—there are few stronger. But there is something more than this. There is a sympathy between the Belgians and ourselves over and above commercial interests, and it is shown in their overflowing hospitality and their never-failing kindness.

The stereotyped expression "fine show" addressed by one to another on similar occasions is amply justified. It is more than a fine show—it is a very fine show, and even more elegantly and artistically disposed than usual. It is held in the building called the Casino, which, with the land adjoining, is the property of the Royal Agricultural and Botanical Society of Ghent. The building is so large and so convenient for the purpose that it grieves the visitor from London to know that no such place is at the service of the Royal Horticultural Society. The buildings consist of one large central hall of three aisles separated by iron

pillars, and lighted from the top. At a higher level, and communicating with the central hall by a double flight of stairs, is a series of salons arranged corridor-fashion, with a central dome. In addition to this there is a large temporary wooden annexe, which on former occasions has been quite distinct from the main building, but which now has been made to open out from the upper salons, from which the descent is made by a double staircase. This arrangement, which ensures a larger amount of space under cover, is, we believe, attributable to M. VAN HULLE, and is so contrived that almost the whole of the exhibition may be seen without going out-of-doors. The arrangement of the plants in the

vertical mirror, which gave the impression that the water was actually passing beneath the bridge, whilst, in fact, it only reached to the base of the mirror. On the bridge itself were two collections of Orchids from Mr. PEETERS of Brussels and Mr. DE VINCKE of Brugge respectively; and on the farther side a bank of plants of historical interest, as being special associated with the name of JOHN LINDE, whose bust occupied the centre. This exhibit formed one of the special features of the exhibition, but it is needless to give a full catalogue in this place.

We need say nothing here of the majestic Palms, stately Cycads, elegant Tree Ferns

FIG. 93.—ACALYPHA SANDERI: STOVE SHRUB WITH CRIMSON SPIKES 12 TO 18 INCHES LONG. (SEE P. 241.)

central hall and the annexe has been confided to M. EDWARD PYNAERT, and in place of a heavy, somewhat monotonous arrangement, there is a very light and graceful disposition of plants, &c., which meets with universal approval. Without a plan it is difficult to describe it, but we may say that the boundaries and corners were as usual concealed by noble Palms and stately foliage plants. In the centre was a small piece of water, with a central fountain, and from which rose on one side a bank of Tree Ferns, on the other a similar mound covered with "Dracænas and plants with coloured foliage; and at the foot was a green lawn laid out with beds of richly-coloured Dracænas and Anthuriums in the foreground. The lake was spanned by a rustic-bridge, beneath which was placed a

remarkable Aroids, and other decorative plants. Their imposing effect can readily be realised whilst as for details we may refer to the report on the show at p. 250.

In the upper salons were arranged Orchids, bulbous plants, and miscellaneous plants. Here, too, were the new plants; the collection of twelve exhibited by Messrs. SANDER was allowed to remain uncontested, but it was clear that the Acalypha Sanderi alone was remarkable enough to have carried off the prize itself. We had the opportunity of seeing Messrs. SANDER'S plants before they were sent to Ghent; and descriptions of them, with figures on a much reduced scale are given in the present issue. The other new plants were mostly unimportant, and some were new once

MUCH REDUCED. (SEE P. 243.)

FIG. 95.—*DRACAENA BROOMFIELDI*: HORT. SANDER. LEAVES GREEN, EDGED WITH SILVER.
(See Report of Ghent Quinquennial, p. 250.)

but had ceased to be so. Mr. KEGELJAN'S Gloxinias excited much attention from the great size of the blooms and width of the throat in most of them.

The Annexe, much increased in size from what it was on former occasions, contains generally a splendid collection of New Holland plants, Acacias, Camellias, and, of course, Azaleas of the Indian and mollis sections. Vast mounds of flower, with scarcely a leaf visible, form a mass of glowing colour, without which a Ghent show would hardly justify its name. We must refer our readers to the detailed account in another column for what was by no means the least interesting section of the Exhibition.

Out-of-doors there was not much worth chronicling; but the collection of Conifers of Messrs. BURVENICH, VAN HOUTTE, Père, Mr. KERKVOORDE, and others, deserve notice; and there were also in the grounds some Sweet Bays, Phormiums, deciduous Magnolias, a fine pair of Phoenix canariensis, and a similar pair of Phoenix tenuis, from M. GHELLINCK DE WALLE. Boilers and garden requisites were not exhibited so largely as on former occasions.

As to the proceedings. The jury, upwards of 200 in number, commenced their work on Friday, after an address of welcome from the Comte DE KERCHOVE. Their labours were much facilitated by the appointment to each section of a steward, who knew where every plant was to be found, and conducted the members of the section to the desired spot without loss of time or unnecessary travelling to and fro, such as is so fatiguing on these occasions. The services as messengers of a corps of little boys from an orphanage were also requisitioned. Promptly and well did these little fellows execute their allotted task.

In one or two instances the judging was not in accordance with the relative merits of the case, so far as we appreciate them—but differences of opinion on such points have been known here sometimes!

When the judging was completed, the jurors were invited to luncheon, under the presidency of the ever-active and sympathetic President, whose speeches were, as ever, singularly felicitous and well-chosen. The Minister of Agriculture, the Burgomaster of Ghent, and the President of the National Horticultural Society of Paris, spoke at some length. The last-named, M. VIGER, gave a dramatic touch to the ceremony by presenting the decoration and conferring the "accolade" of a kiss on both cheeks on M. ED. PYNAERT, who by this means received the grade of Chevalier of the Order of the Merite Agricole. No one ever deserved such a recognition better, though we fancy an Englishman would have preferred a shake of the hand!

Another interesting ceremonial was the presentation by Dr. MASTERS, acting on behalf of the Veitch Memorial Committee, of handsome medals to the Comte de KERCHOVE DE DENTERGHEM, and to M. EDOUARD ANDRÉ. What the meeting thought of the propriety of these awards was shown by the prolonged applause that was manifested. A third medal had been awarded to M. LATOUR-MARLIAC, in recognition of his success in hybridising Nymphaeas. M. LATOUR, unfortunately, was unable to be present.

On Saturday morning the delegates from the several societies of Europe, and the members of the jury, had to array themselves in raiment usually appropriated to evening ceremonials in this country. The reason for this, to Englishmen, strange and uncomfortable procedure, was

that the King and Queen were to visit the exhibition as early as 8 o'clock to receive the representatives of the several societies and members of the jury, and to take what we should call a "good look round" before His Majesty exercised his sovereign power by declaring the exhibition open. The King, as is well known, is an enthusiastic lover of flowers; and his reception of the representatives was as gracious and sympathetic as it is wont to be. It will be seen that the royal visit was no mere formal or perfunctory ceremonial.

A visit to the winter-garden of the Dowager Countess DE KERCHOVE was a very enjoyable rest after the business of the morning. The subdued tints of the giant Palms and lovely Ferns were contrasted with occasional masses of colour rendered by Azaleas, Cytisus, and the like; whilst rocks, flowing water, and green turf contributed largely to the beautiful and reposeful aspect of the whole. In the evening a *raout* was given by the Chambre Syndicale in the rooms of the Union Club. The proceedings were of the most hospitable character, but "repose" was not a conspicuous element in it.

On Sunday, the jurors proceeded by special invitation to a garden party at Laeken given by the KING and QUEEN to the diplomatic body and the nobility. This afforded an excellent opportunity for viewing the famous winter-garden which has been figured in our columns. It is now connected by subterranean passages lighted from above, and long rising corridors, lined with Pelargoniums and other flowering plants, to the chapel on the side of the hill, also illustrated in the *Gardeners' Chronicle*. This chapel is in itself a winter-garden, being of iron and glass, circular in outline, and with eight or twelve recesses or side chapels, and decorated with Palms. By means of the passages and corridors above-mentioned, it is possible to go from the Palace through the winter-garden to the chapel, perhaps a quarter of a mile distant, without going into the open air. There is a fine Orangery with three rows of trees, 112 in number, and among the Camellias four giant specimens lately imported from Pallanza, but further details must be deferred till another occasion. Mr. L. VAN OBBERGEN is the highly competent and obliging Director in place of the late Mr. KNIGHT.

On the return from Laeken, the jury betook themselves to the splendid saloon of the Theatre, there to partake of an elegant banquet attended by several state functionaries, and where expression was given by jurors of various nationalities to the feelings of gratitude for the abundant hospitality and unwearying kindness and attention of our Belgian friends. This completed the public festivities. The week following was devoted to the careful investigation of the exhibition, and to visiting some of the 300 nursery establishments of Ghent.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Royal Horticultural Society's Fruit and Floral Committees takes place on Tuesday, April 26, in the Drill Hall, James St., Westminster, from 1 to 5 P.M. On this occasion the National Auricula and Primula Society will hold its annual show. At 3 o'clock a lecture on "Sweet-scented Leaves versus Fragrant Flowers," will be given by Mr. F. W. BURBIDGE, M.A., V.M.H.

HORTICULTURAL CLUB.—The usual monthly dinner and *conversazione* took place on Tuesday evening, April 12, and notwithstanding the holidays and the Ghent Exhibition, which drew off several of the members, there was a good attendance, the chair being taken by Mr. GEORGE PAUL, J.P., V.M.H. The Rev. GEORGE ENGLEHEART, who was

the guest of the evening, gave a very valuable address on seedling Narcissi, in raising which, as is well known, he has been so successful; and he exhibited some of his latest productions that had shortly before obtained prizes and Awards of Merit at the Drill Hall, which were greatly admired. An interesting discussion followed, in which many of those present joined. We hope to give this interesting address in a future issue.

THE ROYAL GARDENERS' ORPHAN FUND.—The executive committee met at the Horticultural Club on the 15th inst., Mr. WILLIAM MARSHALL presiding. The following special donations were announced:—The Kew Guild, per Mr. W. Watson, £2 5s.; the Bradford Paxton Society, per Mr. R. Scott, £1 3s. 8d.; Mr. G. Elisha, per *Gardeners' Chronicle* 5s. The investment of the amount of the J. W. Thompson Trust, and also of the sum of £500, was left in the hands of the treasurer and trustees. The sub-committee appointed to carry out the details of the annual dinner brought up a report relative to the arrangements which had been made to that date. Some further details of business were transacted.

KING'S WEIGH-HOUSE SCHOOL FLOWER MISSION.—We have pleasure in publishing the following note received from Miss F. C. N. ARMBRECHT, hon. sec. of the mission:—"May I again trespass on your kindness by asking you to allow me to make an appeal for flowers for the King's Weigh-House Flower Mission through the medium of your valuable paper. Flowers are distributed to the poor of this neighbourhood every Saturday afternoon during spring and summer. Although in the midst of such a fashionable part of the West End, there are some of the very poorest, and these welcome gladly the bunches of flowers that we bring them, especially the children, some of whom have no idea what the country is really like. Contributions of flowers (wild or garden) should arrive on Friday night or Saturday morning; carriage will be paid, and boxes and hampers returned carriage paid if desired. The parcels should be addressed to Miss ARMBRECHT, King's Weigh-House School, Thomas Street, Oxford Street, London, W.

CAPE OF GOOD HOPE FRUIT.—The *Briton*, of the Union Steamship Company, has arrived with a consignment of 911 boxes of Grapes, and 48 of Pears. The company report that some of the Grapes arrived in good condition, whilst others were poor.

THE FLORAL DISPLAY IN HYDE PARK.—The present appearance of the long series of beds skirting Park Lane, leaves little to be desired, and rarely have the Hyacinths, Tulips, and Narcissus that are planted therein in a variety of mixtures and by themselves shown to better advantage than this year. The configuration of the parterre is such, that if a variety of Hyacinth, Tulip, &c., fails to put in an appearance simultaneously with those in neighbouring beds, no hiatus is caused, as is unfortunately noticeable in some town gardens this season. [This display, barring hot sun or very frosty nights, is likely to be prolonged for ten days from the present date. Especially worthy of notice for pretty effect were the following beds. Jonquilla campervelle planted on a groundwork of Chionodoxa Luciliae; the same variety of Jonquil with a groundwork of Scilla sibirica; Hyacinth Lord Macaulay planted with alternate diagonal lines of Narcissus princeps and edged with double lines of Hyacinth Grand Monarch the light-blue, yellow, and bright-pink of these flowers making a charming whole. Similar was a bed of Hyacinth King of the Belgians, deep pink, Narcissus Golden Spur with Hyacinth Priestly, a light-blue variety that is soon tarnished by the smuts of London. A circular bed of Narcissus Empress standing on a carpet of Scilla sibirica was good. One of N. Horsefieldi, in fine condition, mixed with Tulip Joost von Vondel; the latter, however, was much too late to be effective. A mixed bed of single late Tulips and *Doronicum plantagineum excelsum*; another of mixed Tulips and *Pyrethrum carneum*, neither of these in bloom at the present time. Among the plants used in the beds some remarkable dwarf Wall-

flowers, both yellow and brown, were remarked; besides *Primula polyanthus*, *Tulip Ophir d'Or* struck us, as being an eminently suitable dwarf variety for bedding.

TASMANIAN APPLES.—The officials of the P. & O. Steamship Company send us the following:—"We have received advice by wire of the following fruit: viz., per Orient Co.'s s.s. *Austral* 20,000 boxes, and per P. & O. Co.'s s.s. *Australia*, expected about the 22nd proximo, 8,700 boxes." The *Austral* was stated, on March 19, p. 170, to be due to arrive on May 14.

"JACKS."—"We have got through 20,000 of these during the past winter," said an extensive grower of hardy market plants, the other day, "and we shall put out more shortly." "Jacks" is the grower's appellation of single Carnations, hawked and sold generally as unbloomed unnamed varieties all over the kingdom. The seed stock of plants for this year's blooming shows compact habit, and broad, stout leafage, that resembles the Clove and Malmaison sections. It is this broad leafage which leads to sale. Seeing how readily these single Carnations are raised from seed, it is to be regretted that only the foliage should have its improvements cared for, and nothing be done to improve the flowers. Probably were some enthusiastic florist to take these singles in hand, very fine flowering strains might in time be obtained. There are now beautiful single-flowered Pink^s, why not even more beautiful single Carnations?

OPEN SPACES IN LONDON.—The very important matter of obtaining and beautifying the available open spaces in London continues to receive the close attention of the Metropolitan Public Gardens Association, and at the monthly meeting held recently it was announced that, as the result of the representation of the Association, the Home Secretary had refused to sanction the erection of buildings on the Cross Bones Burial Ground, Southwark. It was also stated that remodelling of Charles Square, Hoxton, had been commenced. It was agreed, if its maintenance were secured, and if funds were forthcoming, to lay out the churchyard of St. Mary, Plaistow, at a cost of about £300. Amongst many other matters which engaged the attention of the meeting may be mentioned Ham Common and Lammas Lands, Bridgewater Square, the "Postmen's Park," Pymme's Park, Edmonton, and some vacant land at New Cross.

A BOTANIC GARDEN FOR ABERDEEN.—It is stated that Miss CRUIKSHANK, sister of the late Dr. CRUIKSHANK, has given £15,000 to the Aberdeen University wherewith to found a botanic garden in memory of her brother.

A PUBLIC PARK FOR LEE.—The Earl of NORTHBROOK has offered to present to the inhabitants of Lee and district a piece of land of about 7 acres in extent adjoining Bromley Road, Lee, as a recreation ground, the only conditions attached to the gift being that the ground shall be taken over by the London County Council, and laid-out and maintained by it as a recreation ground. As building operations are being carried on in the locality, and there was a Board School in the immediate neighbourhood, the Parks Committee of the London County Council have not hesitated to suggest that the Council should undertake the charge of the land on behalf of the public. The value of the land is estimated at a sum of more than £4000, the cost of laying-out, fencing, seats, &c., at £1000, and the annual cost of maintenance at £200.

POTATO-SETS FOR THE IRISH PEASANTRY.—The *Standard*, April 8, states that the Local Government Board has addressed a letter to the Guardians of several Unions in the west of Ireland, stating that representations having been made to the effect that many persons employed on the relief works have been unable to avail themselves of the Seed Supply Act this year owing to poverty and the high price of seed, the Government will give a bonus in the shape of a free grant of seed (sets) to families whose

members, resident on the holdings, were employed on the relief works on or before April 6. The entire cost of the grant will be borne by the Government, and is to be regarded as an additional recompense for the labour given. All the Unions to which the letter has been addressed have accepted the offer.

"THE FERN BULLETIN."—This is the name of a small quarterly pamphlet edited by W. N. CLUTE, published at Binghamton, U.S.A., and "devoted to Ferns." The first number of the sixth volume is before us, and contains the following papers:—"Four new species of *Ophioglossum*," E. G. BRITTON; "*Woodsia ilvensis*," C. F. SAUNDERS; "*Asplenium fontanum* in the West," B. D. GILBERT; "New *Isoetes*," A. A. EATON; "Development of Ferns from Spores; *Botrychiums* in an odd place, and Naturalisation of exotic Ferns. A recent development of *The Fern Bulletin* is the inclusion in it of four extra pages devoted to the Mosses. This department is edited by Dr. A. J. GROUT, and constitutes a decided improvement in, and attraction to the little magazine. The second number has arrived as we are going to press.

PUBLICATIONS RECEIVED.—*The Country Gentleman's Catalogue* (Eden Fisher & Co., Clement's Lane, Lombard Street). A useful annual for those to whom it is addressed, as it deals with agriculture, gardening, sport, and all other country occupations and interests. — *Investigations on the Native Vegetation of Alkali Lands*, by J. Burtt Davy. Published by the University of California, at Berkeley, Cal.—*Recent Laws against Injurious Insects in North America*: together with the laws relative to foul brood, compiled by L. O. Howard.—*Bulletin No. 13*. New series. U. S. Department of Agriculture. Washington Government Printing Office.—*Some Miscellaneous Results of the Work of the Division of Entomology*, prepared under the direction of L. O. Howard, entomologist.—*Bulletin No. 10*. New series. U. S. Department of Agriculture. Washington Government Printing Office.—*The Journal of the Royal Horticultural Society*, for April, 1898. Vol. XXI, Part 3. The present volume is filled with very interesting matter concerning such subjects as manures specially adapted to the needs of Tomatoes, embodied in a communication by Mr. W. Nield; the depth in the soil at which plants occur, by Professor Oliver, with illustrations of the contractile power of roots in some kinds of plants; and a communication on hardy plant-borders, by Miss Jekyll, V.M.H., and Mr. H. Selfe-Leonard, made clear by means of a series of diagrams and keys to the same. Those interested in the artificial raising of Orchids will find an abundance of observations in Mr. C. C. Hurst's paper (read on October 12, 1897), on the "Curiosities of Orchid Breeding."—*The Producers' Gazette and Settlers' Record*. Western Australia (E. S. WIGG & SON, Printers, Hay Street, Perth, W.A.)

PLANT PORTRAITS.

APPLE REINETTE DE CAUX, *Bull. d'Arboriculture*, &c., March.

BUDDLEIA VARIABILIS, Hemsley, *Revue Horticole*, March 16. A species like *B. Lindleyana* but with a denser and broader spike. The flowers are lilac. It is a native of the mountains of Ou Pé.

CALLISTEPHUS SINENSIS, *Garden*, March 26.

HIBISCUS CAMERONI, *Garden*, April 2.

PYXIDANTHERA BARBATULA, a charming little plant, difficult to grow here, but which thrives in a poor sandy soil on which Pines grow. *Meehans' Monthly*, March.

ROSE, TEA, Mdle. Yvonne Gravier, *Garden*, March 19.

SOLANDRA GRANDIFLORA, *Garden*, March 12.

Obituary.

AIMÉ GIRARD.—We regret to announce the death of M. A. Girard, an efficient populariser of science in relation to the cultivation of the land, and a veritable benefactor to French agriculturalists, especially in reference to the cultivation of Sugar-beet and Potatoes; and the results of his investigations and experiments in these and other directions were made known throughout the civilised world. M. Girard was in his 68th year,

GHEENT QUINQUENNIAL.

NEW PLANTS.

If there was not quite so keen an interest shown in this department as on the last occasion, there was nevertheless a fine and interesting collection. The most prominent were the new plants shown by Messrs. SANDER of St. Albans and Bruges. Indeed their *Acalypha Sanderiana* was the plant of the show, and its remarkable appearance, and brilliant crimson pendulous spikes attracted universal admiration. Most of these plants are described and figured in the present issue.

Aralia Balfouriana, also shown by Messrs. SANDER, had trifoliate leaves, the ultimate segments rounded, green, with white edges. *Saintpaulia ionantha* was shown for the first time at the previous quinquennial, and was now exhibited by M. DE CONINCK, with leaves variegated with yellow. *Licuala Jeananceyi* was shown by Messrs. SANDER. It is a Fan Palm, with deeply lobed leaves, the stalks of which are beset with hook-like spines. The same firm also showed *Ptychosperma Sanderi*, with pinnate leaves and very narrow segments, a very elegant species; and *Calamus caroli*, a pinnate-leaved twining Palm, with spreading spines. Other new plants are alluded to under various headings.

GENERAL STOVE PLANTS.

Never have stove foliage plants been exhibited better, even at a Ghent show. Under various headings we have referred to some of the principal plants in this section, especially those that have a claim to be new or rare. To the classes themselves, however, in which the exhibits were remarkable only by reason of the exceptional cultivation presented, we have not space to allude to in detail. One of the principal of such classes was that for twenty-five foliage plants, which was won by M. H. MILLET, of Ledeberg. The best twelve *Crotons* (large) were exhibited by the Société Horticole Gantoise. From this same establishment came the best group of twenty-five Palms; and M. J. MOENS, of Ledeberg, showed the best group of fifteen plants. The many small classes with prizes for the best example of different species of Palms were the means of bringing together such excellent specimens as Englishmen rarely see—save, of course, at Kew. The best collection of fifteen Cycads was shown by M. DE GHELLINCK DE WALLE of Ghent.

MM. DURIFZ FRÈRES, of Ghent, showed an interesting collection of medium-sized specimens of no fewer than twelve species and varieties of *Asparagus*, all of them well cultivated. These were *A. compacta nana*, *A. comorensis*, *A. plumosus nanus*, *A. decumbens*, *A. falcatus*, *A. medius*, *A. plumosus*, *A. p. cristatus*, *A. retrofractus arboreus*, *A. falcatus albus*, *A. tennissimus*, and *A. Sprengeri* in fruit.

MM. RIGOUT showed a fine plant of *Asparagus Sprengeri* variegata, the narrow phylloclades edged with silver.

THE ORCHIDS.

At the last show five years ago, the place of honour was occupied by the two memorable groups, replete with rare things, staged by the leading Belgian amateurs, M. GEORGES WAROCQUÉ, and M. JULES HYE-LEYSSEN, and on that occasion each competitor did his best to secure the coveted medal offered by His Majesty the King.

This time the nurserymen entered the lists, but as there were two important medals offered, the one great exhibitor entered for the King's Medal, and the other for that offered by M. le Comte de Germiny, and consequently, as in very many instances throughout the show there was no competition, the prize going to the only exhibitor. These two important groups were staged side by side in the new (inaugurated 1868) Salon, or Winter Garden, and both were admirable in every respect.

The Gold Medal offered by His Majesty the KING, for the best 100 Orchids, was taken by M. VINCKE-DUJARDIN of Bruges, his group being characterised by the number of fine *Odontoglossums* which he so well cultivates. Among them we noted *O. crispum grandiflorum*, *O. c. Trianei*, *O. c. punctatissimum*, and other fine varieties of *O. crispum*; *O. excellens*, remarkably good *O. Pescatorei*, fine *O. Wilckeanum*, *O. polyanthum*, the singular and pretty *O. Scheepdaelense*, a curious intermediate variation between *O. crispum* and *O. Andersonianum*; and a number of fine hybrids of the *O. Andersonianum* class. In the background appeared the fine old *Ansellia africana*, with the brightly-coloured *Epidendrum O'Brienianum*, tall spikes of *Oncidium lamelligerum*, *O. superbiens*, *Cymbidium eburneo-Lowianum*, and other elegant varieties; and among the dwarfier plants remarkable were *Cattleya Lawrenceana superba*, with petals as brilliantly coloured as the lip; *Miltonia Bleuana nobilis* of fine form; *Eulophiella Elisabethae*, the fine scarlet *Epiphrontes Veitchii*; *Cattleya Schroderae*, *C. intermedia Parthenia* and other fine *Cattleyas*; *Lycaste Skinneri alba*, fine *Masdevallia ignea* and *M. Lindeni*, *Oncidium spillopterum*, and numerous handsome *Cypripediums*, &c.

M. A. PEETERS, of Brussels, secured the Gold Medal offered by M. le Comte de Germiny for the best 100 Orchids, comprising the best species and varieties, with one of the most beautiful and well-arranged groups of finely-cultivated Orchids which could possibly be brought together at this season. The group was conspicuous by the number of richly,

FIG. 96.—RFSTIO SPS.: F. W. MOORE. (SEE P. 243.)

FIG. 97.—CERATOLOBUS MICHOLITZIANA; HORT. SANDER. (SEE P. 243.)

coloured varieties which it contained, and very attractive to the eye were fine plants of *Epiphrontis Veitchii*, the bright yellow and purple of *Lælia Latona*, the violet hue of the ample labellums of the several varieties of *Zygopetalum Perrenoudii*; the varied and softer tints of the new *Phaius Norman*, *P. Norman roseus*, and *P. N. aureus*; and the rich orange colour of *Masdevallia Veitchii*, every plant being arranged to show itself effectively. In the back-ground were elegant sprays of *Oncidium sarcodes*, *O. Marshallianum*, *Lælia purpurata*, *Cymbidium Lowianum*, *Odontoglossum Hallii*, and other graceful species. And among the rare gems may be selected the pure white *Cattleya intermedia Parthenia*, the white petalled *C. Mossiæ Reineckiana*, the hybrid *C. Parthenia*, and its rose-tinted variety *gratissima*; *Miltonia Bleuana nobilior*, *Eulophiella Elisabethæ*, *Masdevallia Veitchii grandiflora*, *Lycaste Skinneri alba*, *Odontoglossum coronarium brevifolium*, some very fine *Cattleyas*, *Odontoglossums*, &c.

The plants in the other classes were chiefly arranged on the staging running down the centre of the old, or upper salon, and much care must have been taken both in allotting the spaces to suitable plants, and in the arrangement of the various exhibits with an edging of Ferns and other foliage plants so as to form an effective arrangement as a whole.

To Mr. WILLIAM THOMPSON, of Walton Grange, Stone, Staffordshire, belongs the honour of sustaining the credit of British Orchidists, and well did he accomplish the duty, so far as *Odontoglossums* are concerned at least, the noble plants which he staged in Class 88 (collection of thirty *Odontoglossums*) being generally admitted by the cleverest Belgian growers to be equal to anything they could ever desire to attain. The plants were large, having been successfully grown on for some years, their bulbs of great size, and plump and healthy; their foliage clean, and verdant; and their flowering grand, both as regards the size of the individual flowers, and the strength of the spikes, which were in many cases branched. The Gold Medal was awarded by the jury, *par acclamation*. Among Mr. THOMPSON'S best plants were *Odontoglossum crispum Thompsoniæ*, one of the largest and best of the typical *O. crispum*; *O. c. Annie*, a handsome flower, richly spotted with purple; *O. c. leucoglossum*, a fine rose-tinted form with white lip; a grand *O. Ruckertianum*, with two fine spikes; the fine *O. Wilckeanum concinnum*, *O. W. compactum*, and *O. W. nobilior*; a grand series of distinct forms of *O. luteo-purpureum*, including *O. l. leopardinum*, *O. l. Waltoniense*, *O. l. amplissimum*, and a noble *O. l. hystrix*, with three very fine spikes. Also in the collection were a splendid *O. Roezlii album*, some fine *O. Pescatorei* vars., *O. triumphans*, *O. Coradinei expansum*, as large as ordinary *O. Wilckeanum*; *O. Rossii majus*, a magnificent *O. Humeanum splendens*, &c.

Mr. THOMPSON also showed in class 57 (for the best *Odontoglossum*) a noble example of *Odontoglossum Hallii*, with nine spikes, and with it secured the 2nd prize, the 1st going to that enthusiastic amateur, M. METDEPENNINGEN, Boulevard du Jardin Zoologique, Ghent, who showed *Odontoglossum Madame Metdepenningen*, a charming and very distinct natural hybrid, with large and finely-formed flowers of a clear pale yellow, beautifully blotched with red-brown. Although it may be likened to a broad-petalled *O. Wilckeanum*, its origin is not easy to determine, for the flower has a slight suggestion of *O. excellens*, the plant itself being much like *O. Pescatorei*.

M. METDEPENNINGEN also secured the 1st prize (*Medaille de Vermeil encadrée*) for the best fifteen *Odontoglossums*, showing fine *O. crispum*, *O. Andersonianum*, *O. Pescatorei*, *O. Rossii majus*, *O. odoratum album*, &c., and the 1st prize for the most beautiful *Odontoglossum crispum* (*Alexandræ*), with a noble variety of the large unspotted type.

In Class 27 (Amateurs), (collection of fifty Orchids in the greatest variety), the Gold Medal was awarded to M. F. PAUWELS, of Antwerp, for a good collection, in which the most interesting and valuable plant was *Odontoglossum Pauwelsianum*, a very neat cream-white flower spotted with brown, the oval fringed lip seeming to suggest it as a hybrid of *O. Hunnewellianum*. In the centre of the group was a good *Cymbidium Lowianum*, and with it *Odontoglossum læve*, *O. Uro-Skinneri*, *Vanda tricolor*, a fine *Dendrobium superbum*, *Odontoglossum Hallii* and other good *Odontoglossums*, *Vanda tricolor*, *Coryanthes macrantha*, *Lælia-Cattleya Schilleriana* (as *L. elegans*), *Cattleya citrina*, with six flowers; *Angraecum sesquipedale*, *Cypripedium villosum*, with twelve flowers; *C. Rothschildianum*, with very strong spike; *Oncidium Marshallianum*, *Phalenopsis Schilleriana*, and several other excellent examples of Orchid culture, such as a fine *Cypripedium Chamberlainianum*, *Odontoglossum Rossii* var. *grande*, with about thirty flowers; and the fine old *O. hastilabium*, in exceptionally good condition.

Class 30 (Nurserymen), for the best thirty Orchids, brought two competitors, the 1st prize (Gold Medal) being taken by M. LOUIS DE SMET-DUVIVIER, of Mont St. Amand, Ghent, for a really fine stand of excellent Orchids, which formed an admirable object on the central end of the stage which they occupied in the old salon. Well elevated at the back was a grand specimen of *Cymbidium Lowianum*, with many arching spikes; with it were fine *Oncidium lamelligerum*, *O. Sarcodes*, *O. superbium*, a fine example of the violet-coloured *Odontoglossum Edwardi*, *Cymbidium eburneum*, *Lycaste Skinneri alba*, *Cattleya Mendeli*, *Ada aurantiaca*, *Odontoglossum triumphans*, *Masdevallia Harryana splendens*, *M. ignea aurantiaca*, *Miltonia vexillaria*, *Oncidium phymatophilum*, &c.

The 2nd Prize in Class 31 was secured by Mr. H. VANDER STRAETEN, of Bruges, in whose collection the *Dendrobium clavatum*, *Cypripedium Calypso*, *Cattleya Schroderæ*, *Lycaste*

Skinneri alba, and the *Odontoglossum cirrhosum* were specially good.

The Williams' Memorial Medal offered for the best fifteen Orchids (amateurs) was awarded to M. METDEPENNINGEN of Ghent (à l'unanimité), who staged excellent examples of *Cattleya amethystoglossa*, *Vanda suavis*, *Oncidium sarcodes*, *Odontoglossum Andersonianum*, *O. Ruckerianum*, and *Masdevallia ignea aurantiaca*.

Class 33 (for collection containing the greatest number of species, only one of each species) fell, as could be expected, to the enthusiastic amateur, M. VAN IMSCHOOT of Ghent, whose collection not only receives the showy kinds, but the botanical species. As a result, the collection staged was of far greater interest to the plantsman, or to any who would stay and examine some of the lesser beauties than more showy and perhaps more striking groups. Upwards of ninety distinct species were well represented in M. Van Im Schoot's group, the most striking plants being a fine specimen of the rare *Dendrobium cymbidioides*, with eleven spikes; a curious *Odontoglossum* of the crispum section, with yellow flowers, and named *O. sulphureum*; a nice plant of *Dendrobium Kingianum*, *Lycaste lasioglossa*, and other *Lycastes*, *Odontoglossum Edvardii*, *O. Erstedii*, *O. Hunnewellianum*, *Cattleya labiata Luddemanniana*, *C. Schroderae*, *Epidendrum Stamfordianum*, the rare rose-coloured *E. Cooperianum*, and other *Epidendrums*; *Cypripedium Harrisianum superbum*, *C. Salicifolium*, *Phalenopsis Boxalli*, *Selenipedium Dominianum*, and some pretty little *Erias*, *Pholidotas*, *Masdevallias*, &c.

M. VAN IMSCHOOT also secured the Medal offered for three new hybrids, with good specimens of *Masdevallia Pourbaixii*, *Epidendrum Endresio-Wallisii*, and *Cattleya Albertii* (*Loddigesii* × *superba*), a pretty hybrid, with pale pink sepals and petals, and a rich purplish lip.

In Class 34 (three Orchids of different genera remarkable for good culture and flower), M. L. D. SMET-DUVIVIER, of Mont St. Amand, Ghent, was awarded the Medal, his excellently-grown exhibits being *Oncidium sarcodes*, with five spikes; *Odontoglossum luteo-purpureum*, with two spikes and a fine plant of *Cymbidium Lowianum superbum*.

The Classes for Single Specimens (other than the *Odontoglossums* before-mentioned), brought little competition, and the exhibits in these classes were not very remarkable, though most of them were good show-plants.

For the best *Cattleya*, the Medal was awarded to M. LANGHE-VERVAENE, for a good example of *Cattleya Schroderae*, with about twenty flowers.

For the best *Lælia*, the Medal fell to M. CHAS. MARON, Brunoy, near Paris, for a good example of the fringed-lipped *L. Digbyana*.

For the best *Dendrobium*, the 1st prize went to M. DE SMET-DUVIVIER, for *Dendrobium thrysiflorum*, rather past its best.

For the best *Oncidium*, the 1st prize was secured by M. L. P. LANGHE-VERVAENE, of Brussels, with a grand example of *Oncidium sarcodes*, which, however, was only the best of a number of others of the same species which he exhibited, and all of which had been grown for some time, and had now assumed (for the species) gigantic proportions, their spikes being about 5 feet high, and laden with flowers. A curious fact should be recorded about these plants, viz., that they were grown in ordinary pots, and potted much in the same way as the *Azaleas*, the compost used being the ordinary leaf-soil (*terre de Belgique*) of the Belgian Nursery. The pots are said to have but few cracks, and the leaf-soil is surfaced with sphagnum moss. Water is freely given during active growth, but very sparingly afterwards. Many *Oncidiums* are said to thrive equally well in this way, though some other Orchids are not amenable to the treatment.

Class 66 (for the best hybrid Orchid) brought a very beautiful, remarkable, and distinct plant, *Lælio-Cattleya* "Henry Greenwood" (*L.-C. Schilleriana* (*Stelzneriana*) × *Cattleya Hardyana*) exhibited by the raiser M. CHAS. MARON, Horticulteur, Rue de Montgeron, Brunoy, Paris. In habit of growth the plant resembled a very strong *Lælio-Cattleya elegans*. Its flowers, which were as large as a good *Cattleya gigas*, were quite novel in the form, especially of the showy labellum. They had white sepals and petals delicately tinted with rose; the fine lip chrome yellow in the throat, and rich purplish crimson in front. The jury, of which Mr. Jas. O'Brien was president, and M. M. Cabuzac, secretary, unanimously voted a higher award than that specified in the schedule, and a Silver-gilt Medal was given.

M. MARON also showed fourteen plants of *Cattleya L. Chaton* (*Trianei* × *Lawrenceana*) like, but larger than *C. Lawrenceana*; several plants of *L.-C. intermedio-flava*, and one of the yellowish rose-tinted *L.-C. Bertha Fournier*, scarcely expanded.

In Class 68 (for the best twenty-five *Cypripediums*) the Gold Medal was secured by Ghent's favourite nurseryman, M. PYNAERT VAN GEERT, with a splendid lot of well-grown plants, most profusely flowered. In front was a plant of the pure white *Cypripedium bellatulum album*, and behind it a noble specimen of *Cypripedium Mastersianum*, with seventeen of its pretty wax-like flowers—perhaps the best specimen of its kind ever exhibited. Specially noteworthy, even where all were good, were a fine variety of *C. exul* with ten flowers, a grand *C. nitens superbum*, *C. Helène Gayot*, *C. macropterum*, *C. Doris*, fine varieties of *C. Lathamianum*, *C. Calypso*, and kindred hybrids, among which was a remarkable and showy variety named *C. Lambertianum*.

In the same section for amateurs, M. J. MOENS secured the Medal with nice specimens of *Cypripedium Niobe*, the glossy, darkly-coloured *C. Chas. Madoux*, *C. Hebe*, *C. Lecanum Albertianum*, *C. Harrisianum violaceum*, a finer *C. Salicifolium*, and other good things.

The Gold Medal offered for six *Vandas* was awarded to M.

VINOKE-DUJARDIN of Bruges, for healthy specimens of the *V. tricolor* class.

The Gold Medal for ten *Anæctochilus* and allied genera fell to M. PYNAERT VAN GEERT, who showed some remarkably fine *Anæctochilus Petola*, *A. xanthophyllus*, *A. setaceus*, *Goodyera Rolissonii*, &c.; the 2nd prize going to M. A. DALLIERE of Ledeberg, Ghent, who also showed remarkably healthy specimens of this difficult class; the *Anæctochilus Sanderianus* being specially good.

Among other exhibits, mention should be made of a fine little collection of *Odontoglossum crispum* of a remarkably good type, and excellently well grown, staged by M. A. VAN BEERLÈRE, Chaussée d'Anvers, Ghent, and among which was a very handsome form of *O. Ruckerianum*, with large, cream-white flowers, profusely spotted with red, and with yellow margin to the petals; and also of two remarkable varieties staged with their new plants by Messrs. F. SANDER & Co., of St. Albans and Bruges. The first was the very handsome and distinct *Odontoglossum Roi Leopold*, a truly unique form, with cream-white sepals, tinged, especially on the reverse side, with rose, and decorated with clusters of rather large red brown blotches; petals rather broader, and fringed at the edge, white, clouded with clear rose, and bearing many irregularly-displayed reddish spots. The lip is narrow, elongated, fringed, and apiculate, white with a lemon-yellow crest, and a few brownish blotches and some smaller purple ones. The other novelty was *Lycaste Skinneri* Baroness Schroder, which may best be described by likening it to a *L. S. alba* of the best type, with a delicate blush-pink tint on the sepals, and a more pronounced pink-marbling on the petals, the lip being pure white, with light yellow callus.

Turning to the schedule, we can but remark on the number of classes in which there were no entries, perhaps providentially, for if a much larger proportion had entered, and there had been competition in the classes, it is difficult to say where the plants would have been placed, for the show was full enough as it was. Still, by comparison with species better represented at former shows, such as *Lælia purpurata* and other showy kinds, it seems most likely that the past long, though not hard winter may be accountable for the deficiency—indeed, some of the growers remarked that in many cases buds had been held in check by absence of sunlight, until they either failed altogether or came out crippled.

HARDY BULBOUS PLANTS.

In a competition for the best collection of 150 *Hyacinths*, in fifty varieties, a grand lot from Messrs. BYVOET BROTHERS, Overveen, Haarlem, obtained 1st prize, an "Œuvre d'Art." All of the varieties were the most popular ones, and were shown in capital style. Seldom have we seen better developed flowers of *Czar Peter*, *Charles Dickens*, *La Grandesse*, *King of the Blues*, and others. The only new one was *Ivanhoe*, a purple-blue flower, with fine bells upon a spike of considerable length. A Gold Medal in this class was also awarded to L. VAN HOUTTE, Père, Ghent.

Messrs. BYVOET Bros. were also successful in staging the best collection of 100 *Hyacinths* in an equal number of pots; and a Gold Medal was awarded to the second best exhibitor in the class, viz., M. K. J. KUYCK, of Billegom.

A collection of 250 *Hyacinths*, in twenty-five varieties, from Mr. H. J. KUYCK, Hillegom, Holland, staged with a large mirror at the back, was imposing. Ten bulbs of one variety were in each pan. Most of the varieties were familiar ones in England. Yellow was represented by the variety *Ball of Gold*, a large, densely-flowered one of moderate colour. Fine white varieties, and a very pale flesh, were included in the group.

The Société Anonyme, L. VAN HOUTTE, Père, had 1st prizes for collections of fifty single-flowered varieties, and an equal number of double-flowering varieties.

A collection of 300 *Tulips*, single-flowered, in thirty varieties, was remarked from Mr. H. J. KUYCK, of Hillegom. Its yellow varieties included *Yellow Prince*, *Goldfinch*, *King of the Yellows*, *Prince de Ligne*, and *Mon. Tréson*, the last-named being the largest flowered. Thomas Moore, a kind of orange-red, was as distinct as any.

The collection of 300 double-flowering *Tulips*, from Mr. H. J. KUYCK, in not fewer than thirty varieties, were of good quality. There was little new to remark in the varieties, but they had been cultivated well, and were tastefully presented. From pure white to darkest crimson selfs, and variously coloured *Tournesols*, including an effective orange-flowered variety of uncommon tint, also feathered and flamed varieties of double *Tulips*, the collection was a satisfactory and representative one.

M. H. KRELAGE, of Haarlem, exhibited a collection of fifty plants of broeder or Darwin *Tulips*. Some of these were upwards of 3 feet in height, the flowers at the same were fine.

Two collections of fifty pots of *Narcissus*, in as many varieties, exclusive of the *Polyanthus* and *Jonquil* section, were commendable, by far the better exhibit being that from Mr. H. J. KUYCK, Hillegom, Holland; but it was surprising that both collections lacked *Glory of Leyden*, *Weardale Perfection*, and others of the best and newest of the trumpet section.

A collection of twenty-four pots of *Polyanthus Narcissus* was a remarkably good collection, also from Mr. H. J. KUYCK.

HARDY PERENNIAL PLANTS.

The classes in this section numbered nineteen, but only four of these obtained entries. The quality of the exhibits was not so good as we are accustomed to see in this country.

A collection of twenty plants of *Astilbe* (*Spiræa*) *astilboides* from M. A. DE MEYER, Gendbrugge, was the most noticeable

HARDY ORNAMENTAL PLANTS.

M. E. BEDINGHAUS was awarded 1st prizes in the four principal classes in this section. He included in his group specimens of *Skimmia oblata variegata* and the green type *Pernettya mucronata* (large plant, but poorly berried), the small-leaved *Ilex Fortunei* and *J. F. variegata*, *Skimmia japonica* (well berried), rather poor specimens of the variegated *Privet*, various *Ivies*, and other plants; but nothing novel was remarked, nor were the specimens better than we see in England. His *Euonymuses* in many instances were well berried, and the foliage was clean and well coloured winning prizes for twelve plants and for six plants.

The best-berried *Aucubas*, however, were shown by M. F. BURVENICH, Père, of Gendbrugge, near Ghent, several of these plants being attractive specimens, and winning prizes for fifteen plants and for six plants—in the latter class being judged from the standpoint of cultivation.

Ivies and *Hollies* were shown in groups. The best collection of twenty *Hollies* was from Soc. Anonyme L. VAN HOUTTE, Père; and the best group of fifteen *Ivies* by M. BEDINGHAUS. Most of the specimens in both genera were standards, and of fine size and form.

Skimmia japonica was well berried in a group of twenty-five plants, from M. F. COLLUMBIEN, of Ghent; and M. B. SPAE exhibited a nice group of twelve plants.

M. F. BURVENICH obtained a Gold Medal for a group of seventy-five evergreen trees, and there were many other classes for *Agaves*, *Yuccas*, *Furcraeas*, *Cactuses*, *Conifers*, &c.

SOFT-WOODED AND HERBACEOUS PLANTS.

The best collection of twenty-five plants of *Primula obconica* was staged by MM. VILMORIN, ANDRIEUX & Co. Paris, who excelled M. L. de Bock of Ghent. MM. Vilmorin showed strong plants of the white and tinted-flowered varieties.

Of single-flowered zonal *Pelargoniums* the best collection of twenty-five plants were those from M. KERVYN, Oudt Mooreghem of Mariakerke, Ghent (amateur), and from M. L. DE BOCK, nurseryman, Ghent.

A collection of double-flowered varieties was shown by M. J. B. TILLIEN, Boisfort. The variegated foliage section was represented only moderately.

Cinerarias were exhibited in quality about equal to the English average; and in the Amateurs' Class for forty plants M. E. FIERENS, the secretary to the society, was awarded a medal, obtaining similar fortune for twenty plants. Of the nurserymen, MM. VILMORIN, ANDRIEUX & Co. won for twenty plants, but for a group of forty plants they were beaten by M. A. DE VRIESERE-REMENS, Ghent. The last-named exhibitor had a collection of thirty plants of *Mignonette* of satisfactory quality.

Herbaceous *Calceolarias* were not equal to our own collections at the Temple Show, but the Belgian plants have to be fit for exhibition six weeks earlier than the Temple show is usually held.

A collection of fifty plants from Chevalier HYNDERICK DE THEULEGOET (amateur) obtained a Medal; and the best plants from a nurseryman were shown by MM. VILMORIN, ANDRIEUX & Co.

GREENHOUSE BULBOUS PLANTS.

This section included the *Hippeastrums*, *Cyclamens*, *Begonias*, *Gloxinias*, &c. The best *Hippeastrums* were from England.

In the competitive classes, Messrs. R. P. KER & Sons, Aigburgh Nurseries, Liverpool, won in every case, though in some of the classes there were several competitors. The firm had collections of seventy-five plants, of forty plants, of twelve plants (new varieties), of six plants (new varieties), and of a new plant obtained from seed, and not previously exhibited before this society. Messrs. Ker's strain is well known in England, and instead of particularising varieties, we may say that the plants were the subjects of general praise, and that the principal prize (Work of Art) was awarded unanimously, and with commendations by the jury.

Mr. H. KRELAGE exhibited in the class for forty plants, and won a Gold Medal.

Cyclamens were exhibited from one establishment only, and M. L. P. DE LANGHE-VERVAINE, 150, Rue de Constantinople, Saint Gilles, Bruxelles, was awarded 1st prize for fifty plants in flower, and for twenty-five plants; in this latter class a Medal, offered by the Trustees of the Williams' Memorial Fund was also won. All of the plants belonged to the "Papilio" strain, recently exhibited at the Drill Hall, and illustrated in these columns. Several rose-coloured forms with narrow margins of straw-colour to each segment, were curious.

There was one collection of *Gloxinias* shown by Mr. KEGELJAN, of Namur, of very remarkable quality, most of the flowers being nearly 5 inches across, with very wide throats. In this strain the flowers were for the greater part spotted ones. Beyond this exhibit, *Gloxinias* call for little comment. They were of average quality only.

A collection of thirty plants of *G. crassifolia* came from the establishment of L. VAN HOUTTE, Senior, Gendbrugge; and in the *C. punctata* section, M. A. VAN LAETHEM won for thirty plants; and the same firm had the best collection of twenty plants to name.

The date was evidently too early for the perfect exhibition of tuberous-rooted *Begonias*. There were only two groups, and the plants, though in flower, were but little developed. These exhibits were from the nurseries of L. VAN HOUTTE, Senior.

STOVE AND GREENHOUSE FLOWERING PLANTS.

Collection of twenty-five plants for the stove and greenhouse, to be specimens of good culture. Cape and New Holland plants predominated in this class, and the specimens in many instances were not only remarkable for their size and healthy growth, but also for the profusion of bloom. Freedom from overtraining was also notable. Several competed here; the following were the two best collections.

The 1st prize was awarded to M. EMILE DE COCK, Ghent, but the opinion of many who are plant-growers inclined to question its correctness from many points. This group was somewhat uneven in character and the arrangement scarcely so effective, the finest of the large specimens were *Polygala Dalmaisiana*, extra fine; *Rhododendron Gibsoni*, well-flowered and effective; *Metrosideros semperflorens*, a tall standard; *Sparmannia africana*, a dense bush well flowered; *Camellia Lavinia Maggi*, with fine blooms in quantity. Of the smaller, the best were *Acacia grandis*, *A. verticillata*, *Azalea linearifolia*, very singular, covered with its mauve-pink flowers; *Boronia elatior*; *Aphelaxis macrantha rosea*, a good plant, and *Medinilla magnifica*; and a pleasing dwarf standard of *Acacia cordata*. The 2nd prize went to M. E. BEDINGHAUS, Ghent, who should have been placed 1st, as his plants betokened higher cultivation, freshness, and were finer as specimen plants. With one exception this collection was composed of greenhouse plants only, and it was well worthy of the best days of these plants in England. The largest and finest were *Acacia longifolia*, of pyramidal form, and about 9 feet in height; *A. verticillata*, a denser bush; *A. armata robusta*, extra fine—a mass of flower; *A. Drummondii*, a lovely example of medium size; *A. gracilis*, deep golden colour—extra good; *Diosma ericoides*, large, studded with its small white flowers; *Cytisus racemosus*, large, densely flowered; *Eriostemon floribundum*, a fine specimen, and very effective; and the rarely seen *Brachysema acuminata*. The smaller plants of this group were equally notable for their profusion of flower. The best were *Polygala Dalmaisiana*, a pretty standard; *Leptospermum scoparium*, *Eriostemon linifolium*; *Boronia heterophylla*, *Adenandra fragrans*, and *Libonia floribunda*, all models of good culture; of special note, too, were *Metrosideros semperflorens*, richly coloured; *Darwiniana tulipifera*, *Correa speciosa*, and *Anthurium Scherzerianum*. An immense *Azalea indica* Alfred Edmond, some 6 feet across, in this group was profusely flowered, but it betokened decreased vigour. A collection of smaller plants in this class included the now rarely-seen *Kennedya purpurea* and *Boronia Mollini*, a blush-pink variety.

For a collection of fifteen stove and greenhouse plants the competition was again good, but the plants were somewhat smaller. To M. BEDINGHAUS the 1st prize was awarded. This collection comprised a fine pyramidal plant of *Acacia longifolia* and smaller ones of *A. Drummondii* and *A. verticillata* well flowered, a large *Azalea Marie Van Houtte*, and beautiful, although rather small, example of *Chorozema cordata splendens*, and was an even well-arranged group of plants.

Another good collection came from M. VAN DRIESCHE, Ghent. Here the best examples consisted of *Erica cucullata* (like *E. melanthera*, but much larger in the bells, a densely flowered-plant of medium size; a good standard of *Leptospermum bullatum*, and another of *Rhododendron fragrantissimum* bearing large flowers, *Cliveia miniata*, and *Erica arborea* were to be noted here. The 2nd prize was, however, awarded to M. EMILE DE COCK, who had possibly a better collection, his best being *Diosma alba*, *Acacia grandis*, *Boronia elatior*, *Azalea Countess de Flandre*, and *Acacia paradoxa*, extra good.

For twenty plants of *Cliveias* (nurserymen) some good exhibits were to be seen. The 1st prize was awarded to M. CHARLES VERMEIRE, Gendbrugge, Ghent, and comprised a specially fine collection, all the varieties being up-to-date, the best were *Roi Léopold* (extra bright), *John Laing*, *Mme. Jules de Cock*, *Ch. Vermeire*, *Princess Clementine*, and *Chevalier Heyndrickx*, a brilliant variety. The 2nd prize went to M. B. FORTIE, Ghent, the trusses here were in several cases extra good, the finest varieties being *Madame Arthur de Smet* and *Madame Victor Charon*.

For a collection of twenty plants of *Boronia elatior*, the 1st prize was awarded to the preceding exhibitor. This exhibit comprised nineteen plants of medium size, about 12 inches by 18 inches, very dense and compact, and profusely flowered, and another large and extra fine specimen, a model of good culture. The 2nd prize was awarded to M. E. COLUMBIEN DE MEIRELBEKE, whose plants were not so much advanced, but otherwise well grown and healthy.

For twelve standards with stems of about 2 feet high of *Boronia elatior*, the 1st prize was awarded to M. E. COLUMBIEN for a set of excellent plants, the heads about 2 feet through, but not sufficiently advanced to be effective.

For a pair of specimen Orange trees in fruit, the 1st prize was awarded to M. VAN DE WYNCKEL, and the 2nd to M. GULINCK, each collection being well fruited.

Two collections of twenty-five Orange trees in pots were staged, both alike remarkable for profusion of fruit and healthy foliage. The 1st prize was awarded to Mons. CHAS. VAN DE WYNCKEL, Ghent, who had the largest plants, bearing both fruits and flowers, and quite in character with the Orange. The 2nd prize went to Mons. EMILE SOSSY, Mont St. Amand, Ghent; these had their fruits in closer compact, but were void of flowers, but very showy.

For thirty Cape and New Holland plants (nurserymen), M. E. COLUMBIEN, Ghent, took the 1st prize, the group consisted of medium-sized plants of *Boronia megastigma*, *Acacia paradoxa*, *Polygala Dalmaisiana*, *Boronia Mollini*, *B. heterophylla*, *Correa speciosa*, and other species.

For a collection of ten Cape and New Holland plants, M. BEDINGHAUS was awarded the 1st prize, being the only exhibitor. His finest plants were large specimens of *Acacia verticillata*, *A. longifolia*, *A. paradoxa*, *Polygala Dalmaisiana*, and *Leptospermum scoparium*.

For a collection of thirty plants of Cape and New Holland subjects (amateurs only) M. BEDINGHAUS was awarded the 1st prize (the only one awarded), the group consisted of medium-sized examples, all well flowered, the best being a grand plant of *Clianthus magnificus*, a good *Acacia longifolia*, *Erica mediterranea*, *Acacia paradoxa*, and a pretty plant of *Pimelea spectabilis*.

For the best *Polygala*, the 1st prize was awarded to a standard example of *P. Dalmaisiana*, from M. BEDINGHAUS.

For twenty Cape and New Holland plants, the 1st prize was awarded to the Comtesse DE KERCHOVE, who again was the only prize-winner. This collection was of high-class quality, the best being *Acacia Drummondii*, *Choisya ternata*, *Acacia Latrobei*, a lovely variety, very graceful; *Diosma cordata*, and *Cytisus racemosus*. The same exhibitor was 1st also for the best specimen of *Eriostemon*, with *E. floribunda*—a shapely specimen.

For six specimen *Cliveias*, the 1st prize was awarded to M. BAUMANN, of Ghent, whose plants were specially fine, bearing large trusses of brilliant colour, with extra good foliage—a fine lot of plants; and the 2nd to Madame V. SNOECK, Gendbrugge, whose plants averaged about five spikes to each plant, bright and showy.

For twenty greenhouse *Rhododendrons* (Javanese and Himalayan forms), the 1st prize went to M. BAUMANN, whose plants made a fine display, very extra-well flowered. The best were *R. Dalhousieanum*, *R. fragrantissimum*, *R. roseum odoratum*, *R. Gibsoni*, and *R. Aucklandi*.

For six *Cytisus racemosus*, the 1st prize was awarded to M. DE COCK of Meirelbeke, who exhibited tall standards, with dense heads, well flowered.

For twenty Cape and New Holland plants (nurserymen), M. JULES DE COCK, Ledeberg, Ghent, was a good 1st with an even and well-grown lot of plants, the best were *Acacia verticillata*, *A. paradoxa*, and *A. spiralis*, *Boronia polygalifolia* (a distinct variety), *Erica cucullata*, and *Azalea dianthiflora*, a novel and distinct plant. The 2nd prize went to M. DE SARGHER, Ghent, his best being *Boronia elatior*, *Polygala grandiflora*, *Acacia linearis*, and *Sparmannia africana*.

For a specimen *Sparmannia*, M. A. DE VRIESERE-REMENS, Ghent, was 1st with a large standard, well flowered.

For *Choisya ternata*, M. COLUMBIEN was 1st, his plants being compact and well-flowered, a pretty lot.

With an *Acacia* (specimen) the 1st prize was awarded to M. VERRAENE-VERVAERT for *A. spiralis*, a well-flowered pyramid; and the 2nd to M. C. DE SOORE, Meirelbeke, for a fine dense plant *A. paradoxa*.

For a specimen of *Metrosideros semperflorens*, M. L. BERCKELAERS, of Antwerp, was 1st, with a splendid specimen, most profusely flowered, being compact and very healthy, and some 4 to 5 feet through. This plant was one of the most novel and distinct specimens in the exhibition.

For the finest specimen of *Boronia elatior*, a most remarkable plant was exhibited, in every sense a perfect specimen, some 3½ feet high from the tub, and 4 feet through, being one mass of flower. This was shown by M. TH. PIENS, of Melle, and well deserved the 1st prize awarded.

For a specimen *Rhododendron* (hardy type), M. EMILE DE COCK was 1st with a dense, well-flowered plant of *Marie Van Houtte*.

For forty *Rhododendrons* (hardy), large bush-plants, the 1st prize was awarded to ED. PYNAERT VAN GEERT, Ghent, whose group made a fine display. The best were *Sir George Whitworth*, *Madame Wagner*, *I. Fiala*, *Notabile* (cerise colour, distinct), and *Prince Camille de Rohan*; also pretty plants of *Cynthia*.

For twenty-five plants, M. B. FORTIE was 1st with medium-sized plants: the best were *Madame Carvalho* (pure white), *Madame Wagner*, *Comte de Kerchove*, *Cynthia*, *William Austin*, *Doncaster*, *Lord John Broughton*, and *Prince Camille de Rohan*.

In a class for 100 Roses in pots, that number of standards were staged (this style meets with favour evidently on the Continent). The only competitor in this class was M. VAN DER HAEGHEN DE NÈVE, who staged a very neat group of clean fresh-looking plants, which included several of the best Teas, as *Elise Heymann*, *Charles Lemburg*, *Etoile de Lyon*, and others.

A class for the finest lot of *Maréchal Niel* Roses in pots again produced standards only. These came from the same exhibitor as the preceding, and were first-rate, several being with large specimen heads and the flowers of excellent quality.

LILACS.—For ten Lilacs, double-flowered, M. LEMOINE ET FILS, Nancy, was 1st, with small plants. The best was *Madame Casimir Périer* (white), *Charles Joly* (lilac), and *Abel Carrière* (pale lilac).

For a group of Lilac *Marie Legrange*, M. DE BOCK was 1st, the plants being pure in colour and freely flowered. The last-named exhibitor was also 1st for a collection of ten plants, single varieties, the best being *Charles X.*, *Marie Legrange*, and *Virginalis*.

For collections of forty plants in or out of flower three remarkable groups were arranged, the prizes being given in memory of Mr. Louis Van Houtte, Père. The decision of the judges as regards the 1st and 2nd prizes was, however, decidedly open to criticism. The 1st prize was awarded to the SOCIÉTÉ HORTICOLE GANTOISE, Ghent, whose plants were bright, clean, and effective in arrangement; it consisted, however, of several soft plants, which, however effective, should not carry too much weight. The finest plants here

were those of *Licuala grandis*, an immense plant, in fine health; a large one of *Philodendron corsianum*, another of *Anthurium Veitchii*, well developed; *Nephtytis picturata*, extra good in colour and growth; *A. crystallinum*, a pretty plant; *Phoenix Roebelinii*, quite a specimen plant; *Phyllotanium Lindenii*, in good character; *Dieffenbachia nobilis* and *D. Fournieri*, both well coloured; *Spathiphyllum picturatum*, *Dracaena Godseffiana*, *D. Sanderi*, and *Leea amabilis*, all neat, well-grown plants of medium size; a fine plant of *Cyanophyllum magnificum*, and another of *Heliconia illustris*; and three good Orchids, *Oncidium sarcodes*, *Cypripedium villosum*, and *Masdevallia Veitchii*.

From Messrs. ALBERT RIGOUTS, Meirelbeke, came a group which consisted of many extra fine specimens, which, by reason of the narrow pathway in front of the group, could not be seen to such good advantage. These were awarded the 2nd prize, in our opinion they were amply worth a 1st prize: the central plant was an immense example of *Zamia Altensteini*, flanked by fine plants of *Cocos Weddelliana* and *Verschaffeltia splendida* with an unusual number of leaves, and backed up by *Crotons Williamsi* and *C. Queen Victoria*, *Dieffenbachia imperialis nobilis*, extra fine; *Anthurium Hookeri*, *Dichorisandra argentea*, *Schismatoglottis Roebelinii*, *Polypodium difforme macrophylla*, *Allocasia Thibautiana* and *Cyanophyllum magnificum* were all excellent plants; *Phyllotanium magnificum*, exceedingly fine and well-coloured; *Vriesia Moensii* and *Phoenix Roebelinii* were all unique plants, so also were *Dracaena Sanderi* and *Heliconia illustris*. Three good Orchids, all better than those in the 1st prize were staged here, viz., *Oncidium ampliatum majus*, *Cymbidium Lowianum*, and *Odontoglossum luteo-purpureum*; there was also a grand plant, finely-flowered, of *Erica Cavendishi*, with quite a gem in *Anæctochilus petala*. The 3rd prize was awarded to M. L. VAN HOUTTE, Père, amongst which were fine plants of *Erica Cavendishi* and *Pimelea spectabilis*, *Cymbidium Lowianum*, *Dracaena Godseffiana*, *Croton Warreni*, and *Anthurium Veitchii*; it contained, however, some eight or ten small plants, which detracted from the imposing effect that otherwise might have been secured.

For twenty plants in a smaller but corresponding class, a good collection was staged by M. G. VANDEN ABEEL of medium-sized plants, the best being *Anthurium Veitchii*, *Philodendron corsianum*, *Dracaena Sanderiana*, *Heliconia illustris*, and *Cymbidium Lowianum*. M. RIGOUTS also showed in this class, his best examples being *Curculigo recurvata variegata*, *Dieffenbachia Leemanni*, *Nephtytis picturata*, and *Aglaonema costata splendens*.

For twelve *Dutzia gracilis*, M. EMILE DE COCK was 1st for twelve dwarf, lushy plants, scarcely in flower.

Strelitzia regina, of which four plants were to be shown were a novel feature, having several of their curious yellow and blue flowers. The 1st prize was awarded to M. GUSTAVE BOTELBERGE, Melle lez-Gand.

COOL GREENHOUSE PLANTS.

The best pair of *Dracenas* (Cordylines), remarkable for culture and development, were two plants of *D. Douceti*; these were quite unique plants, being specially well coloured; these came from M. P. PERRÉ.

The same exhibitor also took the 1st prize for a pair of the same variety in another class, being almost as good as the preceding exhibit.

In a class specially for *D. Douceti*, M. G. GYSELINCK was 1st with a pair of perfect specimens, well clothed with luxuriant foliage. M. J. DE COSTER came in a good 2nd in this class, only lacking colour to have pressed the 1st prize pair very close.

For a pair of *Dracena australis aureo-lineata*, another grand pair of plants was staged, with very broad and massive foliage down to the tub; these were shown by M. G. GYSELINCK. The 2nd prize in this class went to MM. HENRI LYPPENS & Co., Moerbeke, for a smaller pair.

For a collection of six plants of *Dracenas* (Cordylines), variegated forms, the 1st prize was awarded to M. P. PERRÉ for *D. Douceti*, in which there were distinct variations of marking and habit.

With *Phormium tenax variegata*, M. VERGAUTEREN was 1st, the plant well furnished with foliage.

For six plants of *Phormiums* in specimens, the 1st prize was awarded to M. JULES DE COCK, who had *P. atropurpureum*, *P. atropurpureum striatum* (distinctly fine), *P. versicolor*, a dwarf variegated form, *P. Veitchii*, erect in growth, and freely variegated; *P. Colensoi*, and *P. tenax variegata*, the last being severely trimmed.

With a pair of *Phormium tenax*, M. J. DE SÆGHER was 1st, the plants extra large and bushy, being really tubful of plants bedded out.

For three plants with fine foliage for a cool-house, the 1st prize was awarded to M. VOORTMANN, Ghent, with *Agave americana*, *Phoenix tenuis*, and *Phormium Colensoi* variegatum, the latter a specially fine example.

For twenty-five plants for the cool-house with variegated foliage, M. ADOLPHE DE MEYER, Gendbrugge-lez-Gand, was 1st, his exhibit consisting of really useful plants suitable for the purpose. The best were *Dracaena Douceti*, variegated *Phormiums* and *Eleagnus*, *Nerium Oleander variegatum*, *Ligularia Kämpferi*, and *Aspidistra elatior variegata*, with a very pretty example of *Rhodeia japonica fol. aur.* var. M. JULES DE COCK was 2nd in this class, with good plants of *Phormiums*, *Euonymus*, *Ivies*, variegated Orange, &c., all being well grown.

For twelve varieties of Bamboos the 1st prize was awarded to M. JULES DE COCK, for tall plants chiefly, but no real novelty was apparent, the best example being of *B. aurea*.

For a collection of eight ornamental foliage plants, M.

GEORGES FRETIN was 1st with well-grown examples, amongst which were *Rhopala corcovadense* and *Cocos insignis*.

For a collection of twelve ornamental plants that can be used for the out-door garden during the summer, M. BEDINGHAUS was easily first with grand examples, the finest being *Doryanthes Palmeri*, a splendid plant; *Dasyllirion longifolium* also extra good; *Elaeagnus reflexa marginata*, a huge plant of dense growth; *Phormium tenax atropurpureum*, a huge plant; *Phoenix tenuis*, equally fine; and *Yucca aloifolia quadricolor*; with good plants also of *Phormium tenax variegata*, *Brahea Roezli*, with glaucous and *Dracena indivisa lentiginosa*, with coppery foliage.

For the largest collection of greenhouse hard-wooded plants, which were not in culture in Europe on January 1, 1893, outside of Botanic Gardens, the following exhibit did not strictly comply with the foregoing terms—at least, not so far as British gardens are concerned. M. BEDINGHAUS was the only exhibitor, this collection being staged in one of the glass erections in the grounds. It consisted of half and quarter specimens, with some small ones, being an exhibit of special interest. The most noticeable were *Erica affine*, *Diosma ambigua*, *Hibbertia volubilis* (very distinct, flowers yellow), *Erica imbricata*, *E. persoluta alba*, *Tieria Smithi* (Eriostemon-like in flower and growth), *Tremandra verticillata*, and *Acacia cordata*.

For a collection of twenty Cape and New Holland plants in pots not exceeding 6 inches in diameter, to be well flowered, the 1st prize was awarded also to M. BEDINGHAUS, who complied with the terms, and won easily, his best plants being *Acacia linearis*, *Erica Cavendishi*, *E. ventricosa coccinea minor*, *Cytisus scoparius Andreanus*, *Leptospermum bullatum*, *Boronia serrulata*, *B. elatior* (very fine, a dense miniature standard), *Polygala grandiflora*, *Epacris miniata splendens*, *Acacia cordata*, *Chrozema cordatum splendens*, and *Grevillea Priessi*. This exhibit was of special interest, as an example of the value of these plants when well managed.

Specimen cool-house Palms. For a pair of *Phoenix tenuis* of large size the 1st prize was awarded to M. DE GHELLINCK DE WALLE, these plants were each about 20 feet through by 15 feet in height, and most dense in leafage; the 2nd was awarded to M. D. J. KUYCK, of Ghent, who had smaller specimens. The finest specimen of *Chamerope humilis* was also from M. GHELLINCK DE WALLE, a well-grown tall plant.

For a pair of *Dracena* (*Cordylina*) *lineata*, two fine examples, from M. H. BERT, were placed 1st, these were very dwarf and dense in foliage.

For a pair of large specimen *Bays*, the 1st prize went to M. L. FRELIN DE MEIRELBEKE, for an immense pair of plants with large dense heads.

PALMS.

Large specimens of most of the well-known Palms and a considerable number of small plants of the rarer species in cultivation were prominent in various positions. The gigantic plants of *Kentia*, *Livistona*, *Cocos*, *Pritchardia*, and *Rhapis* were such as only Ghent can produce at an exhibition. The rarer species were *Phoenix Roebelinii*, a Palm of exceptional elegance, which will become very popular, if only a quantity of seeds of it can be had. *Verschaffeltia splendida*, in the collection of M. RIGOUTS, bearing seven grand leaves on a stem 6 feet high; *Stevensonia grandiflora*, 12 feet high, with leaves 10 feet by 6 feet; *Astrocaryum mexicanum*, with a grand head 20 feet through, on a stem 8 feet high; *Ptychoraphis angusta*, fully 6 feet high, and as elegant as *Cocos Weddelliana*; *Cocos* (*Glaziovæ*) *insignis*, very handsome examples; *Ceroxylon andicola*, the true Wax-palm, a beautiful specimen, with leaves 10 feet long; *Pritchardia Gaudichaudii*, *Brahea dulcis*, *Livistona brachypoda*, a distinct plant, after the style of *L. sinensis*, but with leaf-stalks so shortened as to cause the blades to crowd on to each other; *Corypha nermis Laucheanæ* has longer petioles than the type, and they are purplish at the base; *Ceratolobus concolor*, a plant 4 feet high, with bright green leaves, Caryota-like pinne and brown spines; *Licuala peltata*, several fine plants, labelled *L. Doctor Oxley*; *Wallichia oblongifolia*, *Cocos nucifera*, *Brahea havapensis*, looked suspiciously like *B. dulcis*.

The plants shown as new Palms comprised a number of strikingly distinct and promising introductions, for most of which horticulture is indebted to Messrs. F. SANDER & Co. So far as new plants are concerned, the Palms were a long way in front of every other family. Some of them are described on p. 241. Their names are *Licuala Leopoldii*, a distinct little species with small, circular leaf-blades, divided into spoke-like segments; *Kentia Warteliana*, and *K. Karsteniana* (probably *Ptychospermas*); *Areca Ilsemanii*, *Licuala Jeanneneyi*, *Rhopaloblaste singaporensis*, *Linospadix Petrickiana*, *Calamus Laucheanus*, and *C. Alberti*. Variegated forms of *Livistona sinensis*, *Kentia Belmoreana*, and *K. Forsteriana* were shown, and won admiration, but it is unlikely that they will ever become abundant or favourites, the variegation either dying off soon, or changing to an unattractive hue.

CYCADS.

Numerous plants of Cycads, *Macrozamia*, *Encephalartos*, and other genera of Cycadeæ formed a prominent feature of the exhibition, as, indeed, has been the case at every Quinquennial. Many of the specimens were of large size, and some quite exceptional. They were in good health, and remarkable for the small amount of the root-space afforded them. The names used were confusing to those who know these plants by the Kew name. *Zamia* was used for almost all the genera, even *Cycas* being called *Zamia* in some cases. However, the plants were there to speak to the skillful culture of the Belgian growers; their names can be righted

easily. Prizes were offered for the best of fifteen Cycads, eight Cycads, and seven other classes.

The most striking of the plants shown were *Cycas siamensis*, *Encephalartos Hildebrandtii*, *E. tridentata*, *E. Lehmanni* (shown in one group as *E. Perowskiana*), *E. Altensteini*, *E. caffra*, and *E. Ghellinckii* (shown as a new Cycad, and named *Cycas Speluncæ*). *Macrozamia* were represented by some magnificent specimens. *M. Denisoni*, with a stem 5 feet high, carrying a fine lead of leaves, was exhibited as a new species of *Cycas* under the name of *C. Shepherdi*, from Tonkin! The serrated form of *Bowenia spectabilis* was represented by a many-leaved plant. What looked like a new species of *Cycas* was a small plant said to have come from Tonkin, and shown by the Société Anonyme Horticole, Ghent. It has the habit and general outlines of *C. circinalis*, but differs from it and other Cycads in the rigidity of its leaflets, which were almost as stiff as those of *Dioon*.

AROIDS.

There were many Aroids shown, both in the miscellaneous groups and in special classes. Few plants lend themselves better to the quick formation of large specimens than the *Dieffenbachias*, *Alocasias*, *Philodendrons*, *Caladiums*, &c.; consequently, they are largely grown for exhibition. Such plants as *Nephtytis picturata*, of which there were several specimens 6 feet across and 3 feet high; *Dieffenbachia Jenmani*, the decorative character of which is never so well revealed as it was by some big plants in several groups; *Anthurium Scherzerianum*, in great numbers, showing wide range both in size and shape of spathe, as well as in colour, the latter ranging from deep crimson to pure white, through salmon-pink, rose-pink, and lavender—even yellow—was represented in one called *Vervænanum*. The variety with many small spathes springing from the spadix, and also one with a pair of equal-sized spathes to each spadix, were shown in several groups. The Ghent nurserymen have devoted considerable attention to this plant, which now shows a very striking range of forms, all the result of selection and inter-crossing of varieties for it has not yet been crossed with any other species. *Alocasias* were numerous, both as regards plants and varieties. M. DE SMET DUVIVIER showed a fine collection, which included a form of *A. Sanderiana* called *Gandavensis*, and peculiar in being of a rich metallic-purple; *A. Kerchovei*, *A. Pucciniana*, *H. Watsoniana*, *A. Lowii*, and *A. argyræa* were specially good. One called *A. plumbea* has large dark green crinkled leaves, with purplish petioles. Messrs. SANDER & Co. showed a new one under the name of *A. Wavriniana* (see p. 243). The largest and most striking Aroid shown was a specimen of *Anthurium Hookeriana*, which was like a huge Lettuce, 10 feet across, the oblong leaves being 6 feet by 2 feet. *Spathiphyllum picturatum* has large mottled leaves, and is more like a *Dieffenbachia*. *Philodendron Martinetti* is a new plant, with large dark green sagittate leaves, dark green above, purplish below. *D. Pynaerti* is also a likely plant for large stoves, pillars, and walls. *Dieffenbachia Kerchoveana* is a new plant, after the style of *P. Jenmani*, but with leaves four times as large, and the spots confluent. *Philodendron triumphans*, shown by M. DE SMET-DUVIVIER, is like *P. Carderi*, differing mainly in being a stronger grower, with leaves twice as large. It is one of the best of the genus. M. ALBERT RIGOUTS also showed a fine collection of moderate sized plants, but all the specimens were well grown.

BROMELIADS.

The collections of Bromeliaceæ were as large as is usual at continental exhibitions. Many of the plants were grand examples of culture; the finish they bore as regards leafiness, colour, and in some cases fine flowers, being also exemplary. The giant of the family was a huge specimen of *Tillandsia* (*Vriesia*) *regina*, shown as *V. Bloki*. It was as high as a man, and was in flower. *T. Moensiana*, evidently a near ally of *T. regina*, was represented by a plant 5 feet high, with rigid channelled leaves, 4 inches broad at the base, tapering gradually to the apex, and coloured cream-yellow, with green margins. *T. Martelli* is a variety or near ally of *T. zebrina*, differing in its narrower leaves, and in their being whitish about the base; the flowers were bright red. *Nidularium amazonicum Treyerianum* is a beautiful new plant, which delighted the hearts of lovers of Bromeliads. The upper surface of the leaves is yellow, with green stripes, whilst the under side is of a rich crimson, and green below. It was exhibited by M. DUPRAT, of Bordeaux. *Streptocalyx Vallerandi*, a Pineapple-like plant, with a spike of bright pink flowers, and *Nidularium Makoyanum*, with leaves variegated as in *Dracena Lindenii*, are also worthy of special mention. MM. DUVAL ET FILS showed a fine collection of Bromeliads, including specimens of *Vriesia Pohlmanni* ×, a cross between *V. gloriosa* and *V. Van Geerti*. The plants were dwarf with flat spatula-like spikes of rich orange-scarlet bracts. M. ALBERT RIGOUTS also showed in this class.

FERNS.

Tree-Ferns 20 feet high with enormous heads of fronds formed a conspicuous feature in the large annexe, other groups owing their attractiveness largely to big specimens of such sorts as *Polypodiums*, *Gleichenias*, *Angiopteris*, *Marattias* &c. The most striking Fern among the new plants was one called *Polypodium difforme macrophyllum*, shown by Mr. RIGOUTS, which promises to be a first-rate plant for large houses, its noble pinnate fronds suggesting a Cycad, and its colour a soft moss-green. The fronds measured 5 feet in length, and the pinne 9 inches by 2 inches, and markedly dentate. *Acrostichum Lindenii* is a rare plant with the habit of *Adiantum reniforme*, but shorter in leaf-stalk, the

kidney-shaped fronds being 3 inches across. The variegated *Adiantum Claesianum* was conspicuous among the plants from M. LINDEN. A plant shown as *Marattia orbifolia*, is only *Angiopteris evecta*. *Pteris Drinkwateri*, now recognised in England as one of the best of all Ferns for decorative work, has also found admirers in Belgium. A large plant of *Lycopodium squarrosum* was shown in a group of specimen stove-plants.

MARANTAS, ETC.

The Belgian horticulturists pay more attention to *Marantas*, *Calatheas*, and their allies than the English. Many fine plants were exhibited, and attracted much attention, some of the kinds being pretty and bright in variegation, whilst all were striking. *M. orbifolia* and *M. hieroglyphica*, both forms of the variable *M. fasciata*, are handsome in having roundish leaves a foot or more in diameter, and the veins picked out in other colours than the rest of the plant. *Heliconia illustris* was gorgeous in colours, plants 5 feet high and as much through, being more cardinal-coloured than green. *Cyclanthus bipartitus*, 8 feet in diameter, shown by M. RIGOUTS, *Coccoloba pubescens* 8 feet high, with orbicular leaves from top to bottom, and each a yard across. *Dracena Triomphe de l'Exposition* is a form of *Cordylina australis*, near *Doucetti*, but with the leaf bases tinged with bright red, and the stripes creamy-yellow instead of white. *Leea amabilis*, *Pavetta borbonica*, *Aralia sonchifolia*, *Carlodivia palmata* and *C. palmifolia*, the latter like *P. plicata*, *Strelitzia Reginae*, *Artocarpus incisa*, *Dizygotheca* (*Aralia*) *leptophylla* in flower.

CAMELLIAS.

There were not very many *Camellias* shown, but a few in the Annexe were of good form and well-flowered plants.

For fifteen plants in variety, M. E. DE COCK, Ghent, was 1st, the best being *Lavinia Maggi*, *Bicolor de la Reine*, *Mathotiana alba*, and *Reine des Belges*.

For a collection of thirty *Camellias*, the 1st prize was given to M. LOUIS ECKHAUTE, Ghent, who staged a well-grown and freely-flowered collection of very fine specimens, the best being *Madame Cochet*, *Leeana superba* (grand), *Comtesse Lavinia Maggi*, *Roi Leopold*, and *Mathotiana alba*.

For a specimen *Camellia*, the 1st prize was awarded to M. J. Vervæne, for a well-flowered plant of *Madame Cochet*.

AZALEAS.

The Ghent exhibitions owe very much to the Azaleas of various sections, particularly varieties of *Azalea indica*. We have few such plants as those the Belgian horticulturists take so great delight in. There are few pyramidal-trained bushes, most of them being umbrella-shaped, some exactly so, others, the same form in various degrees of modification. They were arranged in the temporary building known as the Annexe, which, in capacity and in artistic characteristics is exactly suitable to the display of these and similar plants. Standing upon the summit of the staircase that connects the Annexe with the old saloon and gallery, the Azaleas are the most effective feature of the display. They are placed rather closely together in beds a few yards long, and 9 to 12 feet wide. In such a bed not a leaf can be seen, each plant presents an unbroken surface of blooms, and the colour being mixed, the effect is that of a patchwork picture. This floral lavishness is relieved by a *Dracena* or similar graceful plant in a pot placed at each corner, immediately exterior to a narrow verge of grass that is laid around the Azaleas. On Sunday, at mid-day, when most of the visitors were in holiday attire, the scene was remarkably gay. We should add that the paths are metal colour, being laid with finely-broken dark-coloured stone.

The following new varieties of *Azalea indica* are the best of those exhibited by Mr. Jos. Vervæne, 13, Chemin de Rode, Ledeberg-lez-Gand:—President Van Imschoot, semi-double, deep crimson; Madame Joseph Vervæne, a large semi-double flower, salmon-pink in colour, with deep spotted blotch; Madame G. Botelberge, semi-double flowered, purple in colour, very large; Souvenir du Congo, large single flower, purple colour with fine spot; Perle de la Belgique, a very fine double-flowered white variety; Mons. Milland, a semi-double flower, crimson-lake in colour; and Mons. Jerome Vervæne, deep crimson, double flower, very bright.

The following varieties exhibited by M. O. VANDER-CRUYSSSEN of Gerdbrugge are to be commended:—Madame Cuppe, a double-flowered variety, soft pink in colour, with darker centre; M. Emmanuel Aldrufer, a large semi-double-flowered variety, salmon-red in colour, with deep spot; and Madame Arthur de Smet, a distinct flower with white ground, splashed and flaked with purplish lilac.

Messrs. F. SANDER & Co. showed the following new Azaleas:—Mrs. J. Godseff, semi-double, very large red flower, with good blotch; Julius Roehrs, light purple semi-double flower of good form. Mr. O. Thomas is similar to Mrs. J. Godseff, but is a little deeper coloured. Mr. Fred Moore has large flowers of good form, rosy-purple in colour, with effective blotch. Mrs. S. Seager has semi-double crimson-lake coloured flowers.

Of the winners in the various classes for groups of ordinary varieties we can only refer to a few.

The best collection of thirty *Azalea indica* plants was from M. DE GHELLINCK DE WALLE of Ghent; and the best amateur's collection of twenty plants was found in an admirable exhibit from the Comtesse DE KERCHOVE DE DENTERGHEM.

The best group of twenty *Azalea indica* from the trade was shown by MM. Vervæne Bros.; and the best group of twelve plants by M. P. E. DE COCK.

There were several first-rate exhibits in the class for which an object of art, value 200 francs, was offered by M. LOUIS

DE SMET. This was for sixty plants of *A. indica*, of not more than a certain diameter, nor fewer than thirty varieties. The best flowered examples were from Messrs. F. SANDER & Co., Bruges; but, being contrary to schedule in point of height, &c., the collection was placed 4th, and the 1st prize was won by Société Anonyme L. Van Houtte, Père, who had a very fine exhibit.

M. AD. D'HAENE, of Gendbrugge, had the honour to win the class for a collection of 100 varieties.

Azalea mollis was well shown. M. PYNAERT VAN GEERT, Ghent, won a Gold Medal for the best thirty plants; and M. B. SPAE a Gold Medal for twenty plants.

In competition for a collection of twenty plants of hybrids between *A. mollis* × *A. sinensis*, the 1st prize was taken by MM. KOSTER & SONS, of Boskoop, Holland, who also showed a lovely group of the fine variety of *A. mollis*, known as Anthony-Koster, a soft yellow-flowered sort, and one of the very best and most effective of this section. In other classes M. A. DE SMET showed successfully.

FLORISTS' SPECIALTIES.

There were a few exhibits of bouquets, various designs worked with cut flowers, and vases decorated with them, but none of these need to be remarked upon, as generally they were much below in quality those generally exhibited at the Temple Show of the Royal Horticultural Society. At Ghent, the more simple arrangements were the better executed, and they exhibited the better taste.

MISCELLANEOUS.

The best amateur's greenhouse was adjudged to be one shown by M. C. BUSS, of Ghent; and M. J. B. COURT, of Brussels, exhibited a very commendable temperate-house. Statues, vases, plans of gardens, collections of microscopic objects illustrative of the structure of vascular cryptogams, together with various other exhibits of a miscellaneous character added interest to this remarkable show. A very large collection of garden tools and instruments was made by MM. DUTRY, Colson.

ENGLISH EXHIBITS.

The only English amateur who saw his way to exhibit at Ghent was W. THOMPSON, Esq., of Stone, Staffordshire (gr., Mr. Stevens), whose splendidly grown *Odontoglossums* are remarked upon with the rest of the Orchids.

Messrs. JAS. VEITCH & SONS, King's Road, Chelsea, exhibited a group of their strain of *Hippeastrum*, well known over Europe by reason of its excellence, and a very pretty group of *Nepenthes* and other allied plants. A Work of Art was awarded Messrs. Veitch.

The *Nepenthes* included N. *Dicksoniana*, N. *Morganiae*, N. *Burkei* excellens, N. *Hookeriana*, N. *Veitchi*, N. *Curtisi* superba (a very fine plant), N. *mixta*, N. *sanguinea*. There were also *Sarracenia*s Drummondii, *Cheloni*, *purpurea*, and several plants of *Drosera*, *Cephalotus*, and *Heliamphora*.

Messrs. WM. CUTBUSH & SONS, Highgate Nurseries, London, N., showed how in England we cultivate and admire the varieties of *Souvenir de la Malmaison* Carnation, by exhibiting a group of these plants in bloom, including the white flowered variety, and several of the newer-coloured ones. A number of plants in bloom of *Richardia Elliotiana* added interest to this group, which included also a few varieties of winter-flowered Carnations, particularly a very bright one known as Winter Scarlet.

A stand occupied by the JADDO COMPANY, Ltd., Exeter, set forth the claims for this compound, now well known as a rooting medium for plants; various photographs were displayed, which represented some effects of using same.

Messrs. K. P. KER & SONS' *Hippeastrums* from Liverpool, which were so successful in the competitive classes for these plants, are noticed in another column.

The best zonal *Pelargoniums* in this show were same sprays of cut flowers from Messrs. H. CANNELL & SONS, Swanley, who sent some of the brightest of their excellent strain of large-flowered types, and staged them in much the same manner as the firm does in England. Flowering sprays of *Reseda alba grandiflora*; plants of blue-flowered, and other varieties of *Primula vulgaris* were from the same firm.

In so vast a show it is impossible to note even everything that is noteworthy. Next week we shall add a few more particulars concerning the miscellaneous exhibits.

SOCIETIES.

CHESTER SOCIETY OF NATURAL SCIENCE.

THE SAN JOSÉ SCALE PEST.—Mr. Newstead, curator of Chester Museum, who has made an exhaustive study of the San José scale pest, has been lecturing before the Zoological Section of the Chester Society of Natural Science on this pest. Mr. Newstead, who has had an interview with Mr. Long, Minister of Agriculture, and his advisers at the Board, said he had suggested that the Government should engage a staff of trained workers to detect suspicious imports of fruit and submit them for expert examination. The origin of the American fruit-pest scare was due to the action of Germany in March of the present year. That country had passed a law protecting itself from the importation of infested fruit. The oyster scale which infested some fruit trees resembled the San José so closely that it was impossible to distinguish one from the other except by microscopical examination. Mr. Newstead explained the life-history of the insect, showing that after two days of activity in the larval stage it became

an inert fixed mass, living in the same place for the rest of its life and sustaining itself on the tree juice, which in time stunted and diseased the tree. During one season a single female insect was capable of producing 500 or 600 young, and in some parts of America there were five or six broodings. Its presence had been recorded in three places out of America—Australia, Chile, and one of the western islands. He did not think it would thrive in England, but it was very desirable to prevent its introduction. The lecture, for which Mr. Newstead was cordially thanked, was illustrated by micro-photographic slides, drawings, and specimens.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

ON the occasion of the meeting, held at the Corn Exchange, Manchester, April 14, 1898, there were present—Messrs. G. SHORLAND BALL (in the Chair), Law-Schofield, Leemann, Backhouse, Bolton, Johnson, and Gent. (Hon. Secretary).

SAMUEL GRATRUX, Esq., Whalley Range (gr., Mr. McLeod), showed a very fine *Lycaste*, a cross between *L. Skinneri* and *L. plana*, and named Mary Gratrix, the petals of which are of a dark maroon, and the sepals a dull terra-cotta, the contrast being very pleasing. A First-class Certificate was awarded. The same exhibitor also staged a very nice plant of *Dendrobium nobile*. THOMAS STATTER, Esq., Stand Hall (gr., Mr. Johnson), showed a very well-grown plant of *Cypripedium macrochilum giganteum*, which attained a First-class Certificate; and one of *Dendrobium nobile* Backhouseianum. E. J. SIDEBOTHAM, Esq., Bowdon (gr., Mr. Shiner), showed *Cattleya speciosissima*, a fine plant and a good variety, but the flowers not so large as when he showed this plant about a year ago. DUNCAN GILMOUR, Esq., Sheffield (gr., Mr. Day), showed *Cattleya Schroderae* albens. This was entered as alba, but there was the slightest tint of pink in the flower, which caused the committee to give an Award of Merit only; in other respects the flower was first class.

J. LEEMANN, Esq., Heaton Mersay (gr., Mr. Edge), showed a light and distinct form of *Cypripedium Mastersianum* (Award of Merit), *C. Germinyanum* violaceum, *Cattleya Schroderae*, *C. Trianaei*, *Odontoglossum* species, a very fine form in the way of *Ruckerianum* (Award of Merit), and *O. crispum*, a very pretty white form, full and of excellent substance (Award of Merit). D. LORD, Esq., Stackstead (gr., Mr. Swallow), showed a fine form of *Cymbidium eburneum* (Award of Merit). M. G. BUCKLEY, Esq., Saddleworth, showed a yellow form of *Cypripedium insigne*, with rather small flower, accounted for, no doubt, by its being out of season. Messrs. HUGH LOW & CO., Enfield, showed a very fine dark-lipped form of *Cattleya Trianaei* named *gloriosa*, *O. Mendeli*, a very fine spotted *Odontoglossum crispum* called *The Gem* (Award of Merit); *Cymbidium Lowie-eburneum* (Award of Merit); *C. concolor* (Award of Merit); and *Cypripedium James Buckingham*. The same exhibitors also staged a very effective group, including the above-named plants, and a very fine form of *Odontoglossum Wilckeanum*, *O. luteo-purpureum*, *Cattleya Mendeli*, *Oncidium Marshallianum*, *Cypripedium Swinburnii magnificum*, *C. selligerum majus*, and many others. The society's Silver Medal was awarded to this group.

SHIRLEY AND SURROUNDING DISTRICTS GARDENERS' AND AMATEURS' MUTUAL IMPROVEMENT ASSOCIATION.

APRIL 18.—The first monthly meeting of the fifth year of the above Society was held at the Parish Room, Shirley, Southampton, on the above date, Mr. B. LADHAMS, F.R.H.S., presiding, there being an average attendance of the members.

Mr. J. JONES, The Gardens, Terrace House, Polygon, Southampton, gave an interesting paper on "Table Plants, and Plants for House Decoration." A series of questions were put and answered satisfactorily, and a hearty vote of thanks was accorded to Mr. Jones at the close of his paper.

There was a very good show of hardy *Primulas*, contributed by Mr. B. LADHAMS, F.R.H.S.; also *Caladiums*, by Mr. E. J. WILCOX.

READING & DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

ONE of the most interesting and successful meetings yet held, was that held on Monday last, when the prizes offered by Mr. Leonard Sutton at the commencement of the season, 1898, for the best Essays on "How to keep the Greenhouse gay from October 1 to March 31," and "How to crop the Vegetable-garden to ensure the best varieties of Vegetables from October 1 to March 31," were awarded to the successful competitors. The interest taken in the competition was greater than anticipated, thirteen members sending in papers, and it was not a matter of surprise that a good gathering of members assembled on Monday evening, 18th inst., to learn the result and to hear the prize-winning papers read by their writers. After the formal business had been transacted, Mr. C. B. Stevens announced the awards as follows:—

"How to keep a greenhouse gay": 1st, Mr. A. W. BLAKE, Foreman, The Gardens, East Thorpe, Reading (£1 11s. 6d.); 2nd, Mr. G. STANTON, The Gardens, Park Place, Henley-on-Thames (£1 1s. 0d.); 3rd, Mr. JOHN BOTLEY, Foreman, The Gardens, Warfield Hall, Bracknell (10s. 6d.).

"How to crop the Vegetable-garden": 1st, Mr. E. TROLLOPE, The Gardens, Coombe Lodge, Whitechurch (£1 11s. 6d.); 2nd, Mr. H. WILSON, The Gardens, Lower Redlands, Reading (£1 1s. 0d.); 3rd, Mr. G. HINTON, The Gardens, Sherwood Lodge, Reading (10s. 6d.).

Mr. L. Sutton in presenting the prizes said that he considered the subject of essay writing was one of the most useful and beneficial to the members that the society could take up, for it encouraged the putting of one's ideas on paper, and at the present time it was those gardeners that could go to their employers with well-thought-out ideas that would prove successful, and it would also be of the utmost value to the young gardeners who entered these competitions, for they would reap the benefit of their study and research in after life. The president then called upon the various winners to read their papers, and although, of course, all were on the same subject, yet they were treated from different standpoints, thus creating great interest amongst the members present. A hearty vote of thanks was passed to Mr. Leonard Sutton for his kindness in giving the prizes, and also to the members for reading their papers.

Owing to the success of the venture, and the statement by the writers of the assistance they had received from an educational point of view in writing their papers, the Association has decided to take up this interesting subject as a part of their programme for season 1898-99, and a vote was passed that a sum not exceeding £8 should be devoted for this purpose, but that the competition should be divided into various grades, thus giving all members an equal chance to compete.

Cut flowers were staged by Mr. WOOLFORD, The Gardens, East Thorpe, including two good forms of *Odontoglossum crispum*, two fine types of *Cattleya Lawrenceana*, spikes of *Amaryllis* *Empress of India*, and spathes of *Anthurium Scherzerianum* Wardii; also flowering spikes of *Prunus sinensis flore pleno* by Mr. SWANBOROUGH, Warfield Hall Gardens; whilst vegetables were shown by Mr. STONE and Mr. HINTON, including some nice heads of Sutton's April Cabbage.

SOCIETY OF ARTS.

SOURCES OF COMMERCIAL INDIA-RUBBER.

WE publish the summary of a Cantor Lecture delivered by Dr. MORRIS, C.M.G. at the Society of Arts on April 18:—"Since the days when Le Comandante first described the Rubber-tree of Brazil, and Don José, King of Portugal in 1755 sent several pairs of his royal boots to Para in order that they might be covered with the water-proof 'gum elastic,' the use of India-rubber has enormously increased. Besides the demand in almost every department of arts and manufactures, the rapid development of cycling, and of the use of rubber tyres for carriage wheels has added largely to the increased consumption of this interesting article. The quantity of raw Caoutchouc imported into the United Kingdom in 1830 was only 23 tons. Even in the year of the accession of our Queen it was only about 200 tons. Last year it had increased to 20,000 tons—exactly a hundred fold.

The present value of the imports is about 5 millions sterling. The total trade is probably not less than 10 millions sterling. More than one-third of the imports is now received from British possessions. In 1888, only about one fifth was so received. It is estimated that the world's consumption of rubber is 60,000 tons, of the value of fourteen millions sterling. This stupendous quantity of raw material is laboriously extracted from the milky juice of trees or shrubs belonging to three Natural Orders, viz., the Spurge (Euphorbiaceæ), the Nettles (Urticaceæ), and the Dogbanes (Apocynaceæ). These plants are distributed over nearly every part of the tropical zone—none are found in the temperate zones—the most important being found in the vast basin of the Amazon, an area almost as large as that of the continent of Europe; others are found on the east and west coasts of Africa, in Assam, and in the Malay Archipelago.

Hitherto the preparation of India-rubber has depended upon the crude hereditary art of a semi-savage people, the rubber-hunters, who explore the depths of tropical forests and obtain the rubber-milk at the sacrifice of millions of trees, which, owing to the recklessness with which they have been treated, are yearly decreasing.

The result is that many localities where rubber was once abundantly obtained, have almost ceased to produce it. New sources of supply have, it is true, been found in West Africa, especially in Lagos, the Congo State and Portuguese Southwest Africa. But here also the work of destruction is rapidly going on. The collectors have to go further and further into the interior, and the cost of transit is thereby greatly increased. An account was given by the lecturer of an important discovery whereby the rubber could be extracted from the milk in a perfectly pure state. This is a mechanical contrivance on the principle of a cream separator. This was likely to prove of great value in the preparation of Central American and some West African rubbers, where the rubber flows in an appreciable quantity, and is capable of being brought in by the collectors. It would be indispensable on regular plantations of rubber-trees. By such means the process of preparing the rubber could be kept under scientific control, and all injurious substances such as the proteids and all chips and dirt excluded. The value of rubber so prepared has been shown to be increased fully 25 per cent.

The Rubber-trees of Brazil were then exhaustively described, together with the distribution of the various species yielding the Para rubber of commerce. The exports from Para in 1897, including rubber received from Bolivia, Peru, and Venezuela, amounted to 22,650 tons. Of this amount

51 per cent. was shipped to the United States, and 38 per cent. to the United Kingdom, leaving only about 11 per cent. or 2,500 tons for all other countries.

The price of Para-rubber, which regulated the price of all other sorts, has been steadily increasing since 1894, when it was 2s. 11d. per lb.; it 1895 it rose to 3s. 2d.; in 1896 to 3s. 4d.; in 1897 to 3s. 6½d.; while the average price for the first three months of 1898 was 3s. 9½d. At the last sales on the 15th inst. it was 3s. 11d. per lb.

It was, however, pointed out that these prices were below what they were in 1882 and 1883, when fine Para fetched 4s. 4d. per lb.

The next lecture of the series will be delivered on the 25th inst., the subjects treated will be African and Asiatic rubbers, and the prospects of obtaining at least some of the future supplies of rubber from cultivated trees.

THE ROYAL GARDENERS' ORPHAN FUND.

THE annual dinner took place at the Whitehall Rooms, Hôtel Métropole, on Wednesday evening last, Charles E. Keyser, Esq., presiding. The room was fairly well filled with guests, including Sir Trevor Lawrence, Bart., President of the Royal Horticultural Society, and Vice-President of the Royal Gardeners' Orphan Fund, Mr. N. N. Sherwood, Mr. W. Marshall, Mr. Martin J. Sutton, Mr. Leonard Sutton, Mr. A. W. G. Weeks, Mr. G. Monro, Mr. H. B. May, Mr. H. T. Wooderson, and numerous nurserymen, gardeners, and other supporters and friends of the Institution, who would have been more numerous represented, but for the circumstance that many had not yet returned from Ghent.

After the President had proposed the health of Her Majesty the Queen in felicitous terms, he proposed that of "The Prince and Princess of Wales, Patroness of the Fund, and the Rest of the Royal Family," following this with the toast of the evening, "The Royal Gardeners' Orphan Fund." The President alluded in the course of his speech to its origin in 1887, the year of the Queen's Jubilee, and to the great amount of good that it had done in the interval in assisting the orphans and fatherless children of gardeners all over the country. The funded money now amounted to \$10,000, and its income to £1000 a year. There had been from various causes a slight falling off in its annual income, but he hoped that this would prove merely temporary, and that, in spite of the counter attractions in Ghent, the company present would respond fully to the needs of the charity.

The toast of prosperity to the Royal Gardeners' Orphan Fund was responded to by Mr. N. N. Sherwood, treasurer, in appropriate terms, and he indicated a method that might be adopted, of collecting money in aid of the charity, by gardeners enlisting the assistance of their employer's younger children, and providing them with collecting boxes.

The toast of "Gardeners and Gardening," proposed in a few felicitous remarks by Mr. Martin Sutton, was briefly responded to by Mr. A. W. G. Weeks. The amount collected at the various tables during the evening came to the sum of £515, inclusive of £116 from the chairman.

CATALOGUES RECEIVED.

WILHELM PFITZER, Militärstrasse 74, Stuttgart—Plant and Seed Catalogue.

J. W. WIMSETT & SON, Royal Ashburnham Park Nursery, Chelsea, S.W.—Bouquets, Wreaths, Crosses, Sprays, Specimen Palms, &c.

WM. PAUL & SON, Waltham Cross, Herts.—Roses, Florist's flowers, &c.

LOTHROP & HIGGINS, East Bridgewater, Mass.—Dahlias.

TOOGOOD & SONS, Southampton.—Farm-seeds.

APPLE-PIPS AND CHERRY-STONES: *W. L. R.* The first of these are best sown in the autumn in pots or pans of loamy soil, and placed in a cold pit. Apple-pips may likewise be sown at this season in the open ground broad-cast, or drilled at a shallow depth. As a rule, fruit-stones should be layered in damp soil, that is a layer of stones alternating with a layer of soil 2 inches thick, and so on till the whole of the stones are covered. This is the practice when the quantity of stones is large. For an amateur it would suffice to lay them in a box or big flower-pot exposed to the weather, but sunk to the rim in the ground. Autumn-sown pips, and layered Cherry-stones will make their appearance during the spring and summer months.

ARALIA SIEBOLDI: *Aralia*. If in good condition, it would be cheap at 5s.

BOOKS: *Miss G. Morgan*. *Cucumber Culture for Amateurs*, published at the Bazaar Office, 170, Strand, W.C.; *The Tomato and its Culture*, published at the *Journal of Horticulture* Office, 12,

Mitre Court Chambers, E.C.; *The Potato and its Cultivation*, by A. W. Crews, published at the office of the *Field*, Windsor House, Bream's Buildings, E.C.; *Farming for Pleasure and Profit*, 8th edition, by W. Ablet, published by Chapman & Hall, Ltd., 11, Henrietta Street, Covent Garden, W.C.

CARNATION SEEDLING: *W. L.* A full, bold flower, but we notice it has the bad habit of splitting its calyx. Some persons like the indented margin of the petals, as seen in this variety, but we must confess that we do not, as it imparts roughness to the flower.

CARNATION: *A. C.*, *Clontarf*. Your Carnation Countess Ferrars seems to be a very fine and fragrant flower of a very pleasing shade of blush-pink.

CATTLEYA MENDELI: *G. E.*, *Epsom*. The flower, though not large, is very pretty and distinct. The *Dendrobium nobile*, very fine.

CUCUMBERS: *W. W.* Your Cucumbers are suffering from canker of the basal portion of the stem, in consequence of having been planted too deep.

CUCUMBER ROOT: *A. G. E.* Filled with eel-worms. Throw out and char the whole of the soil and plants, starting afresh with plants, soil, and manure from new sources.

CUCUMBERS ROTTING: *London*. Probably the result of eelworms at the root. If so, there is no cure. Please send roots for inspection. The worms you remark in the soil are not eelworms—the latter are much too small to be detected without a microscope.

CYPRIPEDIUM SEED: *E. W.* The seed being the result of chance fertilisation, the blooms may be worthless from a gardener's point of view; but you will not have to put your patience to a longer test than three years before the plants flower. Sow the seed on the surface of sterilised peat, loam, sphagnum-moss, and sand, in a well-drained pan, and keep in the stove.

EUCHARIS: *G. B.* The only course likely to reclaim your stock would be to turn the plants out of the pots, shake off the soil, wash the bulbs and leaves clean in a tub of water, repot into good turfy loam, and plunge on bottom-heat of 80°. Put them into small pots at first, and afford larger ones as required.

HARDY ANNUALS, WHEN TO SOW: *W. L. R.* For this year's flowering, from the present date till the middle of June; and for early bloom next year, in the beginning and end of September in the south.

LAWNS: *Pteris*. If the lawn be very foul, you must relay or sow down anew after manuring and digging it. Directions were given in *Gardeners' Chronicle* Calendar for the Flower Garden on April 9 last.

MANGOLD AND BEET SEED: *Agriculturist*. Two or three seeds are enclosed in the corky calyx of the parent flower, so that when sown two or three seedlings appear at one spot; you should therefore sow in patches of two or three "seeds," at from 9 to 15 inches apart, according to kind and variety, and thin out the least promising seedlings soon after they make true leaves.

MUSHROOM-BED FAILING: *S. W.* The failure of the "buttons" to grow bigger was doubtless due to the almost entire loss of warmth in the bed. For lack of warmth in the soil, field Mushroom-spawn does not grow, or at the least Mushrooms are not commonly observed before the summer sun has raised the warmth of the soil to its highest point, and showers have fallen. A Mushroom-bed should have a sufficient bulk of short stable-dung and droppings from horses fed chiefly on oats and hay, trodden firmly together, to ensure a warmth of about 80° till the spawn is exhausted, say for two months. The spawn may be put into the bed 3 to 4 inches deep, when the warmth is at 98° and declining slowly, and then the soil (loamy) should at once be put on and beaten down. This coating will conserve the heat, which a covering of mats or hay will still further assist in doing, which is very necessary in a glass ventilated freely as such structures must be.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*J. E.* *Hislingbury*. A *Grevillea* or a *Hakea*, we cannot be sure without flowers; South Australian.—*Geo. Doolan*. The hard wood-plant is *Mackaya bella*, the other *Iris fimbriata*.—*R. T.* *Dendrobium bigibbum*.—

T. W. *Ornithogalum nutans*.—*H. B.* 1, *Selaginella Wildenovii*; 2, *Selaginella coccia*; 3, *Maranta zebrina*; 4, *Selaginella viticulosa*; 5, *Ruellia Portellæ*; 6, *Campylobotrys (Hoffmannia) regalis*.—*J. C.* 1, *Ornithogalum nutans*; 2, *Narcissus odoratus flore pleno*; 3, *Corydalis cava alba*; 4, *Fritillaria meleagris variety*; 5, *Scopolio carnolica*; 6, *Triteleia uniflora*; 7, *Narcissus pseudo-narcissus moschatus*; 8, *Uvularia grandiflora*.

NASTURTIUMS AND OTHER COMMON HARDY ANNUALS, &c.: *W. L. R.* The plants should appear in from ten days to a fortnight if sown at the proper depth in warm positions at this season. If the ground is very dry a thorough application of water by means of a fine rose can will help germination. Coarse seeds like those of *Nasturtium* may go 1½ inch under the surface, Sweet Peas 2 inches, smaller seeds ½ inch deep, and very small be sown on the surface, and scarcely be covered at all, merely pressed or beaten into the surface. The minute seeds of *Nicotiana affinis*, *Digitalis*, and *Lobelia* should be sown on the surface of soil, properly prepared by sifting, and put into pans, pots, or boxes, these being placed in warmth.

PTERIS: *I. G. B.* Two or three of the market forms of *Pteris* are more apt to get portions of their fronds between the veining destroyed than others. Woodlice and other insects probably cause the mischief.

PTERIS TREMULA: *Pteris*. We have seldom seen a worse case of scale infestation of a Fern. You can do nothing before cutting all the fronds, and burning them, even then the root-stock will be infested with them, but their numbers may be kept under by extreme cleanliness. First coat the root-stock with clay and cow-dung mixed to the consistency of paint, and thus smother the brown scale insects. The coating falls off in time, bringing the scale with it, and does not harm the Fern.

PURCHASE VALUE OF A SMALL NURSERY: *Corsican*. We are unable to answer your question. Why not consult a practical horticultural valuer?

RED-BORDERED LILY OF THE VALLEY: *D. M. G.* The beauty is quite taken out of the flower by the wretched dye. How could you do it? They will dye the Lily of the painters, or the *Eucharis*, next.

RED-SPIDER ON VINES: *H. S.* The frequent use of the syringe and soft water, as you suggest, would tend to greatly lessen the numbers of this acarus, but it is hardly possible to suppress the plague entirely by that means, and at the same time leave the bloom intact upon the fruit. You would do better to make use of Richards' XL All vaporiser, or of the special kind which he sells for the annihilation of red-spider.

SHADY LAWN: *C. C.* The best kind of grass for growing under trees is *Poa pratensis*. If no kind of grass will grow, plant *Hypericum calycinum*, Irish Ivy, the major and minor varieties of *Vinca*, *Periwinkle*, native Ferns, *Butcher's-Broom*, and plenty of *Snowdrops* and *Crocuses*.

STAG'S-HORN MOSS, ALSO BUCK'S-HORN MOSS: *W. S. T.* This is *Lycopodium clavatum*.

WOOD-LOVE: *J. G.* They may be caught in large numbers in flower-pots lightly stuffed with damp hay, and killed wholesale by pouring boiling water into all cracks, &c. We should suppose that the XL All vapour would be fatal to the insects.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED,
and that it continues to increase weekly.
Advertisers are reminded that the "Chronicle" circulates among GOUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Markets and Weather, see p. xiv.)

THE

Gardeners' Chronicle.

SATURDAY, APRIL 30, 1898.

SOME CAUSES OF FAILURE IN APPLE CULTURE.

ATTENTION has been called by Mr. I. Woolverton, Secretary to the Fruit Growers' Association, Grimsby, Canada, to some of the causes of failure in Apple culture, which will be of interest to many fruit growers in our own country. The following is a summary of some of the main points.

Properly cared for, the Apple orchard is, comparatively speaking, one of the most valuable portions of the farm, even if it is only large enough for home uses. Situated as some farmers are, at a long distance from a railway station, or a good market, the expenses of carting the crop might make the odds against cultivating a commercial orchard; but otherwise, taking one year with another, the author considers the Apple crop can be made to pay twice as well, acre for acre, as a grain crop, all things considered.

1. THE LOCATION OF THE ORCHARD.

A common notion is that any place will answer for the Apple-trees, and therefore very often a stony corner that cannot be worked, or a very heavy clay which one does not want to cultivate, is set out as an Apple orchard. That such an orchard would never be a success goes without proving.

But a more common fault for the location is a wet soil left without under-drainage. Trees in such situations may grow well in summer, but are almost sure to become winter-killed, or at least so injured by the cold in winter that they become enfeebled and unproductive. The remedy is plain, a thorough system of drainage is of the first importance.

Another evil of situation is exposure to high winds. Those who have had almost their whole crop strewed upon the ground in the autumn by wind storms know how to appreciate the favouring protection of a dense wood of deciduous and evergreen trees. This cannot be quickly remedied, but a windbreak of a double row of Norway Spruce-trees will, in a few years, be of inestimable value in this respect.

2. LACK OF CULTIVATION.

The second cause of failure, and one of the most common, is lack of cultivation. Somehow or other, the idea has got abroad that the Apple-orchard needs no cultivation. True, there is no growth of wood, the fruit is small, and imperfect of its kind, but it never seems to occur to the owner that the trees would grow any better for being cultivated; or if he does believe in it, he does not sufficiently value his Apple crop to give it the same attention as he would his grain or Potato crops. There is need of a general waking up in this matter. It has been found that where the orchard is in an

unthrifty condition, so that the leaves are of a light-green or yellowish tint and ripen easily, and the fruit is scant and poor, cultivation is the surest and speediest cure, and will accomplish what pruning and manure will utterly fail in doing without it. Cultivation of the soil so exposes the land to the action of the air as to make available the plant-food which is already there in store; and besides, has a most important influence in counteracting the evil effects of drought.

3. LACK OF MANURE.

Who ever thinks of giving his Apple-orchard an annual dressing of manure? All the available manure is put to the field crops; no farmer would think of growing fine Potatoes, or a paying crop of grain without a heavy application of manure, but the Apple-orchard must shift for itself, without either cultivation or manure, and then if it does not yield a paying crop it is condemned as worthless, and ought to be cut down because it does not pay. Is it the fault of the orchard or of the orchardist? Why should it be expected to do what no other farm-crop could possibly do? Besides, it is most probable that the portion of land selected for the orchard had been under arable cultivation for centuries, and the fertility of the soil well nigh exhausted, before the trees were put in, and these are now blamed for their unproductiveness.

In regard to artificial manures, potash may be considered as one of the most important fertilisers for the orchard. It promotes growth, improves the flavour of the fruit by causing an increase of sugar and a decreasing amount of acid. It improves the colour of the fruit, and this is very important in Apples intended for the market. Apples draw heavily on the soil, and especially upon potash. It has been stated on very good authority that 100 barrels of Apples draw more heavily on the soil for manurial constituents than a crop of fifty bushels of Wheat, and its proportion of straw.

Wood-ashes are always considered of great value for application to fruit-trees. With regard to the action of ashes upon the soil, it is important to notice that a heavy application of unleached wood-ashes to a heavy soil is damaging to its texture, rendering it heavier still, more tenacious, and inclined to be cloddy. But for this reason its action on light soils is highly beneficial, rendering it more compact, filling up the pores and keeping it moist. It also tends to correct "sourness" in the soil by precipitating the soluble iron-salts which are sometimes over-abundant.

Another benefit of wood-ashes is that it promotes nitrification, or the process by which nitrogenous matters in the soil are rendered available for the tree-growth. It is thus evident that ashes have more value than simply for the amount of potash and phosphoric acid they contain, on account of their mechanical action, especially for light soils.

The quantity to be applied may range from about one-half to one ton per acre, or about one-half a bushel to a bushel, per tree of moderate size.

4. RAVAGES OF INSECTS.

The ravages of insects constitute frequently no less important a factor in producing failure in Apple growing for profit than manuring and cultivation. The advantages of spraying for insect pests are now fairly universal among the best growers. Experiments have proved the benefit of copper-sulphate for destroying fungi, and of kerosene-emulsion for such insects as do not eat the foliage, but only suck their nourishment

from the leaves. These discoveries are creating a revolution in fruit-growing in Canada, and making possible the highest success for those fruit-growers who will use to the best advantage the prescribed remedies.

Professor Bailey, of Cornell, says spraying is of some value every year on Apples, Pears, Plums, and Quinces. Nearly all the sprayed orchards are carrying a better foliage than those which are untreated; and where the codling-moth, bud-moth, case-bearer, and other insects are plentiful, it has been of decided benefit. It is recommended to spray thoroughly, or not at all. A tree is thoroughly and honestly sprayed when it is wet all over, on all the branches, and on both sides of the leaves. An insect or a fungus is not killed until the poison is placed where the pest is.

5. BAD HARVESTING.

Even presuming that the orchard has been properly cultivated, pruned, and manured, there are many who yet fail to handle the fruit to the best advantage. In the first place, it is a common mistake to leave the fruit hanging too long on the trees before picking, and in consequence they become too ripe to keep well, and a large proportion is spoiled by falling to the ground. As all the Apples upon a tree do not reach maturity at the same time, it will frequently pay to make two gatherings, leaving the greener and smaller fruits to grow and colour up. Attention to the details of preparing fruit for market always return a good profit, and must not be grudged. Careful handling and careful sorting are of paramount importance. Many throw Apples into the basket as if they were Potatoes, or squeeze them with thumb and finger as if they were made of stone, and so leave marks which spoil their beauty. Round cross-handle baskets, attached with a wire hook to the rounds of the ladders, are the best for Apple-picking.

In Canada most orchardists empty their Apples in piles upon the ground, but sorting in that case is back-breaking work, and every shower of rain delays it. Some empty them in heaps upon a barn-floor, but in a large orchard this means much labour in carting. A better system appears to be, to empty into barrels in the orchard, the heads of which are left in the bottom, and store under cover, and then, in packing, empty them out on a packing-table for sorting. For young orchards and scattered varieties this is certainly the best plan, for the important work of packing can then be done in a clean, dry place, without moving about from one part of the orchard to another.

6. POOR VARIETIES.

Perhaps the orchardist may not have the most profitable kinds of Apples; then top graft with those varieties which are proved most desirable. The work is not difficult or mysterious, but quite practicable by any one who can handle his knife skilfully; but for old trees, a method known as crown-grafting is very well adapted.

There is much difference of opinion as to the relative merits of autumn and spring planting of fruit-trees. We consider the advantages of autumn-planting are several. The trees become established during the open weather of winter, and they usually make a start in spring which is of great benefit; for this early start not only means a better growth the first season, but, what is more important, trees which get a very early hold upon the soil endure the droughts of a hot summer much better than trees planted in the spring. *J. J. Willis, Hecla Villa, Carlton Road, Harpenden.*

NEW OR NOTEWORTHY PLANTS.

GEONOMA? PYNÆRTIANA, Hort. Sander.

SOME doubt must necessarily exist as to the genus of this handsome Palm until it produces flowers and fruits. Nevertheless, even in its present condition it is strikingly handsome (fig. 98). Messrs. Sander's specimen, which was shown among the new plants at the recent Ghent Exhibition, is densely tufted in habit. The leaves are shortly stalked, and, as it appears, destitute of spines, and glabrous. One of the smallest leaves measures 28 inches (71 cent.) in length, by 10 inches (25 cent.) at the broadest portion between the centre and the apex. The form is ob-lanceolate, gradually tapering at the base, and dividing at the apex into two rounded erose lobes, with an acute sinus between them. The midrib is prominent on both surfaces, especially on the lower face. The secondary veins, which are numerous and parallel, form an acute angle with the midrib, and run from it to the margin. Native of Malaya. *M. T. M.*

REMINISCENCES OF GHENT.

IN so vast and varied an exhibition as that held last week at Ghent something must be overlooked. The constant interchange of greetings between friends and colleagues from all parts of Europe, is, moreover, apt to interfere with steady note-taking. We may, therefore, now add a few particulars to our previous report:—

After the new plants, perhaps the most striking feature was the collections of specimen-plants, especially of New Holland and Cape plants. These reminded us of what we used to have in London years ago, till people got tired of seeing the same plants year after year, and in terms of derogation called them "elephan's." At the provincial shows especially, Mr. CYPHER still excites our admiration by his specimen-plants; and the more so, because it is not the mere size that we look to, but the perfection of cultivation, some plants, as every gardener knows, being much more difficult to manage than others—or to use the phrase of the day, some plants do not adapt themselves to their environment so well as others.

The splendid group of stove foliage plants exhibited by M. RIGOUTS and the SOCIÉTÉ HORTICOLE GANTOISE (figured on p. 265), have already been alluded to, as well as the Palms, the Cycads, and the touching group exhibited by M. LINDEN, of which we give an illustration in the present issue (fig. 100, p. 261).

M. BERNARD SPAE exhibited in the annexe a remarkably fine group of greenhouse Araucarias, some being perhaps 10 to 12 feet in height, and beautifully "furnished." They included *A. Cooki*, *Wioti*, *Rulei*, *brasilensis*, *elegans*, *glauca*, *robusta*, *alba-spica*, *plumosa*, and other varieties of excelsa.

Mr. KERKWOORDE, of Ghent, should be mentioned for his interesting group of dwarf hardy Conifers, including a variegated form of *Tsuga canadensis*. The SOCIÉTÉ VAN HOUTTE, Père, also showed good specimen plants of Conifers, but we observed nothing new among them.

Cacti were shown in excellent condition by M. F. DE LAET, of Contich, and by M. BEDINGHAUS, of Ghent, who had some noteworthy specimens of *Echinocactus* of numerous species.

Messrs. SANDER & Co. showed a Wardian travelling-case containing specimens of *Anæctochilus Leopoldi* with deep green velvety leaves, traversed by a whitish or cream-coloured reticulation. The plants had travelled 27,000 kilometres in four months, and though necessarily travel-worn, were, considering all things, in wonderful health and vigour.

M. LÉON DE BRUYN, the Minister of Agriculture, was elected Honorary President of the Jury; M. VIGER, Minister of Agriculture in France, President of the National Horticultural Society of France, was nominated President; the Vice-Presidents being Dr. MAXWELL MASTERS, Member of the Institute of France, one of the delegates with Mr. HUDSON of the R.H.S. of London; M. RUYS DE BEERENBOCK, from Holland; M. FISCHER DE WALDHEIM, Director of the

St. Petersburg Botanic Garden; and Professor WITTMACK, of Berlin. The general secretaries were M. ED. ANDRÉ, of Paris; M. MICHELI, of Geneva; M. H. DE VILMORIN, of Paris; and Dr. BURGENSTEIN, of Vienna. The judges in the section 1 (new plants) were Dr. MAXWELL MASTERS, chairman; MM. ANDRÉ, MICHELI and BOIS. Mr. O'BRIEN was chairman of the Orchid section, and among others of our countrymen occupying similar positions were Messrs. W. BULL; JONES, Lewisham; KER, Liverpool; and OWEN THOMAS. The plants exhibited numbered over 12,000, disposed over a surface of 6752 mètres.

RESPECTFULLY SUGGESTED—1, That in future Quinquennials the columns of the winter-garden be draped with climbers, and that hanging-baskets be suspended here and there from the girders, so as to break the rigidity of the iron-structure; 2, that an office be opened in the centre of the town, where jurors and others might get their tickets on arrival, obtain information and guidance, and especially

exhibitor. For our parts we should have condemned him to take the thing away at once, and banished him from any future competition till his taste improved!

A COLLECTION OF HYACINTHS.—Messrs. BYVOET BROS., Overveen, Haarlem, who won the 1st prize at the Ghent Show for a collection of 150 Hyacinths in fifty varieties, staged the following. We give the list as being in the opinion of the firm, who are excellent cultivators, the most popular selection of fifty sorts.

Single Red.—Belle Querine, Cardinal Wiseman, Charles Dickens, Etna, Fabiola, Lord Derby, Macaulay, Moreno, Mr. Stanley, Mrs. Beecher Stowe, Ornement de Rose, Roi des Belges, Romeo, Solfatara, Von Schiller, Vuurbaak.

Single White.—Alba superbissima, Baroness Van Tuyll, La Grandesse, Leviathan, L'Innocence, Mina, Mr. Plimsoll, Princess Amalia, Snowball.

Single Blue.—Charles Dickens, Czar Peter, Grand Lilac, Ivanhoe, King of the Black, King of the Blue, Leonidas, Lord Derby, Lord Palmerston, Marie, Mimosa, Schotel, Sir Henry Barkley, Starlight, William the First.

FIG. 93.—GEONOMA PYNÆRTIANA: HORT. SANDER (GHENT EXHIBITION).

where the addresses of the visitors staying in the city might be obtained. If each juror would write his name and address, much time would be saved in procuring interviews and meetings between friends—interviews now left to chance.

AZALEA LINEARIFOLIA.—We rarely see any but very small plants of this species in our own country. At the Ghent exhibition there was a specimen about 2 feet high and nearly 3 feet across, exhibited by M. EMILE DE COCK, 56, Boulevard d'Akkergem, Ghent. The plant bore very pale-coloured flowers, and the petals were narrow, but this species is very variable, for small plants from M. LOUIS ECKHAUTE, St. Denis, had rich rose-coloured flowers and wider petals. The latter variety is a very ornamental plant, but doubtless of very slow growth. Some of the plants, although not more than 3 inches high were well covered with blossoms.

WHAT NEXT?—One of the exhibitors of floral devices at Ghent, not content with twisting coloured ribbons around his Araucarias, had so arranged them that bows of ribbon, like those in the bonnets of some ladies, were made to stand up straight above the foliage. We did not see what fate attended this

Single Yellow.—Comtesse de Flandre, Duc de Malakoff, Ida, King of the Yellow, Obelisk.

Single Violet.—Haydn, Sir William Mansfield.

Double Red.—Koh-i-noor.

Double White.—Isabella.

Double Blue.—Laurens Coster.

M. JULES HYE-LEYSEN'S ORCHIDS.—The famous collection of this enthusiastic Belgian amateur Orchid cultivator is soon to have a new home in a fine block of houses to be erected on a very suitable piece of ground, adjoining that on which the Orchid-houses now stand in the Coupure at Ghent. For some time past the confined space in which the Orchids had to be grown, although a very high standard of good culture has been maintained, has entailed on M. Jules Hye, and his diligent Orchid-grower, Mr. Coen, the keenest watchfulness in order to keep the collection up to their notion of what is good condition. Here Odontoglossums reign supreme, and in the collection there are to be found some of the finest and most valuable spotted forms of *O. crispum* and of natural hybrids. We noticed our British variety, *Odontoglossum crispum* Wrigleyanum, in good form; also *O. c. Hyeanum*, one of the handsomest, and *O. c. Albertianum*, the claret-red *O. c. Frantz Masereel*, and other fine forms, all of them in the

most robust health. In flower in the several houses of *Odontoglossums* were remarked some good specimens of *O. crispum*, *O. Pescatorei*, *O. triumphans*, *O. luteo-purpureum*, *O. Wilckeanum*, &c., most of which are selected plants, and some of them are unique.

In the block of smaller houses there were in bloom many rare *Cypripediums*, also good examples of *C. callosum* Sanderæ, *C. Lawrenceanum* Hyeanaum, *C. insigne* Sanderæ, and those two handsome hybrids, *C. × Madame Jules Hye*, and *C. × triumphans*, besides a number of other fine varieties.

Among other good batches noted were selected varieties of *Miltonia vexillaria*, a few of the rare ones being about to expand their blooms, and fine examples of *Miltonia × Bleuana* and its varieties, of which *M. B. nobilior* is one of the best.

In the intermediate-houses in bloom were a few *Cattleya Mendeli*, *C. Trianaei*, and *C. Schroderæ*; *Oncidium sarcodes*, *O. phymatochilum*, *Odontoglossum hastilabium*, *O. Cervantesii* roseum, *Zygopetalum Perrenoudi*, *Lælia × Latona*, *Vanda tricolor*, *Cymbidium eburneo-Lowianum*, and other *Cymbidium*s; and in a sheltered corner plants of *Vanda cœrulea* were doing well. In the small Masdevallia-house the varieties of *M. ignea*, *M. Veitchiana*, *M. Chelsoni*, *M. Lindeni*, and others were remarkably well bloomed.

THE PUBLIC GARDENS.—*The Administration Communale de Gand* has always taken a keen interest in the development of the local horticultural trade, and has continued, so far as the means of the town permitted, to increase the area of the public gardens and squares. M. O. Bruneel, first alderman of the town, being at the same time President of the *Chambre Syndicale des Horticulteurs Belges*, has been director of the public gardens for the last sixteen years, and the progress made during that time will have been noted by the visitors to the successive Quinquennial Exhibitions, but at no former time in so marked a degree as now, when the good work of M. Henri de Wilde, who was appointed superintendent about two years ago, has become apparent. There is an area of land under M. de Wilde's charge of about 30 hectares, consisting of gardens of varied extent, and about 7000 trees in the different promenades of the town, and new avenues and boulevards are being planted every year. A special corps of men, wearing a distinctive uniform, has been organised to keep everything in order. The Square, Van Artevelde, and the garden round the Palais de Justice, are both very neat and well kept; the former bright with Tulips and other flowers, among which were striking lines of blue and white *Muscari botryoides*. In the latter, good specimen sub-tropical plants, such as *Dracænas*, Palms, Bamboos, &c. were effectively planted; the whole square being encircled by a border of Pansies, with a double edging of the fine bluish-white *Ionopsidium acaule*, which M. de Wilde considers one of the best and quickest-raised dwarf edging plants, the plants being procurable in a few weeks to any extent from seeds.

The Square du Béguinage was also very prettily laid out in modern style, although only a few years ago La Béguinage, of ancient reputation, one of the attractions of the town for visitors, was a much more sombre-looking spot. In various parts of the town the squares were bright with Tulips, of which La Reine, Rose Gris de Lin and Belle Alliance were specially showy, and in the square facing the Casino where the show was held, great masses of *Narcissus incomparabilis* and Van Sion were very bright and fresh.

The Great Park on the south side of the town is well worthy of a visit. At present it covers about 16 hectares, and an additional 6 hectares will probably be added soon, which will make it one of the finest parks in Belgium, and highly creditable to the local authorities. At present clumps of *Magnolias*, and other spring-flowering shrubs and plants, make it very attractive.

LEAF-SOIL AS A ROOTING-MEDIUM FOR ORCHIDS.—We were interested when visiting the establishment of L'Horticulture Internationale at Brussels the other day to find that an experiment is being

made there in regard to the possible suitability of ordinary well-decayed leaf-mould as a rooting medium for *Odontoglossums* and other species of Orchids. It would be premature to give the following circumstances as results, for the trial is by no means concluded. Present indications, however, show that the plants root exceptionally freely into the material; that they grow well, develop good foliage, and fat, fleshy pseudo-bulbs, but the flower-stems are weaker, and it seems probable that the plants will flower less well in leaf-mould than in the ordinarily-used compost. All the drainage used in these trials is one crock at the bottom of each pot.

THE ROSARY.

ROSE PROSPECTS.

ALTHOUGH experience has shown us that the prognostications as to the probable character of the Rose season are too often falsified, and that the performance does not correspond with the promise, yet the anxiety to know what is likely to be the character of the season is always a matter which occupies very much the minds of the rosarians as the month of

FIG. 99.—FLOWER OF *PHALENOPSIS SCHRODERÆ* × *P. LEUCORRHODA* × *P. INTERMEDIA* VAR. PORTEI.
Shown by Messrs. H. Low & Co.

(See our report of the Royal Horticultural Society's Meeting in our issue for April 16, p. 238.)

April opens; and never perhaps has there been a more curious state of affairs than in this present year. An unusually mild winter, without frost or snow of any importance, seemed to indicate a very early season, and one was continually asked, as growers saw the growth that was being made, "Ought we not to prune early?" These were the questions of novices mostly; more experienced growers knew that early pruning in such conditions would be injurious, for if the mild weather continued it would induce the lower buds to start, and then these would probably meet with some check afterwards—and so in effect it happened. March of many weathers brought us towards its close what is now the fashion to call a blizzard; in this part of England (Kent), so heavy a fall of snow took place, accompanied by a strong northerly wind, that the roads were in many places blocked, and all forward shoots were considerably blackened, and for a long time there seemed to be a complete stoppage of growth. This, on the whole, was not unfavourable to the Rose, where pruning had not been commenced too early; it gave a check that was much needed, and made such a complete change in the state of affairs that growers began now to talk of a late, instead of an early season. I think, on the whole, this check has been beneficial to the Rose: the wood is sound, there are none of those dark places on the rind which

indicate that the rough hand of frost had laid hold of them. If there have been any losses among Roses during the past winter, it cannot therefore be put down to the effects of frost; and judging from my own small experience, I should say that there were fewer gaps in the Rose-beds this spring than in any previous one that I can recollect. Teas, too, have escaped quite uninjured, and will now be subjected to pruning. I have just finished mine, and they look sound and well; in fact, I do not find in this south-eastern part of England that they suffer more than the H.P.'s. As I have mentioned these, I may allude to the curious alteration that has taken place with regard to them. We are undoubtedly a people who deal in extremes, whether it be in politics, theology, dress, or anything else; we are always subject to what has been called the swing of the pendulum. Some time ago an outcry was made about the neglect of what are called garden Roses, and lamentations made over what were sentimentally called, "the dear old-fashioned Roses." Well, the cry was taken up, and what has been the result?—the great diminution of interest in what are called exhibition Roses; and I am credibly informed by some distinguished professionals that the demand for them by the general public has greatly diminished. Of course, those who wish to exhibit will be as keen on them as ever; but the non-exhibitor is continually told to avoid these "fat Roses," and as what are called garden Roses can be cultivated with less trouble, he is not disinclined to listen to the suggestion. There is another indication of this change in the very small number of new varieties that are offered by the French growers. Time was when it was not unusual to have between forty and fifty of these announced, and I recollect in one year one raiser advertised eighteen new H.P. Roses, and now the last French catalogue does not contain more than half-a-dozen; the usual number, however, is made up by the Teas, hybrid Teas, and other classes which are offered to us. There will not, therefore, be that anxious looking for new varieties at our exhibitions that used to form one of the delightful features connected with our Rose prospects. Of course, it is impossible to say what some of our home raisers may have in store for us. The distinguished firms of Messrs. Paul & Sons of Cheshunt, Messrs. W. Paul & Son of Waltham Cross, and Messrs. Alexander Dickson & Sons of Newtownards, have often surprised us with their novelties. One can well remember the time when *Devoniensis* was the only English-raised Rose to which we could lay claim; then, at many years' interval came John Hopper, and year by year the firms which I have mentioned brought forward some excellent varieties both in Teas and hybrid perpetuals, and continue so doing.

Amongst the new Roses, both British and foreign, which we shall look to see at forthcoming exhibitions, one may especially note *Empress Alexandra* of Russia, from Messrs. William Paul & Son, of Waltham Cross; it is a large globular flower, of peculiar colour, a rich lake-red, shaded with orange and bright crimson. The Rev. Alan Cheales, from Messrs. Paul & Son, a striking novelty, very large, pure lake, with reflexed, silvery-white shaded petals. Mrs. Frank Cant (Messrs. Frank Cant & Co.) is a large, well-formed, and free-blooming Rose of the *Gabrielle Luizet* type, the colour a bright rose-pink, and of a vigorous habit. Then there is *Ulster*, which obtained a gold medal for Messrs. Alexander Dickson & Sons, and promises to be a valuable addition to the series of H.P.'s of which Mrs. Sharman Crawford and Helen Keller are well-known examples; the habit seems to be vigorous, the flowers are freely produced, and are borne on strong footstalks. Again, there is *Countess of Caledon* from the same firm, which ran very close for the gold medal, and appears to be likely to be a favourite for garden decoration, the colour a deep rose.

Amongst the foreign Roses, there are two with the sight of which I have been favoured by Mr. Frank Cant, and which come under the designation of garden Roses, and which, from their peculiar colour, will find favour with lovers of this style of flower; they are pure Teas, with pointed buds, and in their

unexpanded form are very beautiful. One is Madame René Gerard, a large flower of a coppery-yellow colour, shaded with the same colour as Ma Capucine; the other, Souvenir de J. B. Guillot, which ought to be a good Rose, calling to remembrance that most successful raiser of Tea Roses—a very brilliant, probably the brightest of Tea Rose, a red shade of Ma Capucine, passing into a lighter shade of the same colour. Then there is announced a white Maman Cochet; should this be really white, and maintain all the qualities of the flower from which it has ported, it will be a most valuable addition to our white Tea Roses. I cannot come to the same conclusion with regard to a white Maréchal Niel, the glory of that flower being its brilliant yellow colour; its habit is not desirable, as the flowers hang down so, and if the sport does the same, it will not be much of an acquisition. Of course, there are a number of other Roses announced from the French raisers, but they have not been seen on this side of the Channel, and we have long since realised that they see Roses with a very different eye to what we do; so we must patiently wait. I have omitted to mention one Rose which I saw at the Drill Hall as a pot-plant, exhibited by Messrs. Paul & Son, viz., Antoine Rivoire, a clear, deep flesh-colour, with yellow base; it is said to be sometimes flushed carmine, but this colour was not in the flower that I saw. As a pot-plant it seemed to be all that was desirable; and from its good substance, I should think it would do well in the open.

One cannot write about Rose prospects without alluding to Rose exhibitions, and especially those of the National Rose Society. The three exhibitions will be held at the Crystal Palace, Bath, and Halifax; that at the Palace ought to be, if the season be favourable, the best that the Society has ever held. The classes are varied, and great weight has been given to the decorative classes; while one new feature has been introduced, namely, a class for Lord Penzance's Hybrid Sweet Briars, the 1st prize in which has been given by Lord Penzance, and the 2nd and 3rd by Messrs. Keynes, Williams & Co., Salisbury. The two provincial shows will be held in places where Rose shows have existed for many years, and there is no doubt that they will be carried out in the same spirited manner as on former occasions. Altogether, then, our prospects are hopeful; and, should no unforeseen calamity overtake our Roses, we may expect much enjoyment from them. *Wild Rose.*

SCALE INSECTS AFFECTING THE PEAR-TREE.

THE following communication has been kindly sent by Mr. Robert Newstead of the Grosvenor Museum, Chester, in answer to some enquiries made, and specimens of Pear-scale sent by Mr. J. Simpson of Wortley, Yorkshire, who is evidently in doubt as to the names given to these insects by different entomologists, pomologists, and writers on horticultural subjects:—

"The name Pear-tree scale is a misnomer, as it applies equally to four species of scale insects found upon the Pear, viz., *Aspidiotus ostreaformis*, Curtis; *Mytilaspis pomorum*, Bouché; *Lecanium pyri*, Schrank; and *Pseudococcus* sp.

Diaspis ostreaformis was described in error by Signoret (*Essai s. l. Cochenilles*, p. 121, pl. iv., fig. 4), as has been abundantly proved.

Aspidiotus conchiformis, Curtis, does not exist except as a useless synonym of *Mytilaspis pomorum*. The female scales of *Aspidiotus* and *Diaspis* are more or less circular, or irregular ovate; those of *Mytilaspis*, mussel-shell shaped or linear. There is also a marked difference in the form and character of the male scales of these genera.

The late Dr. Signoret wrote the first monograph of all the then known Coccidæ found in various parts of the world. His work, which was completed in 1876, is very valuable and rare, and although out-of-date, is indispensable to the student of the group. Since the publication of Signoret's work there has been a steady increase in the number of workers in this group of insects; but owing to the tedious preparation necessary for the

microscopical study of them, the workers are still few in number. On the Continent we have Dr. Karl Sulc at Prague, Dr. Gustavo Leonardi and Professor Berlese at Portici, Italy; and formerly Mr. Morgan in Portugal. In the United States of America, Professor L. O. Howard, the States Entomologist, and Mr. Theo. D. A. Cockerell, besides several professional entomologists who are thoroughly acquainted with the economic species of that country and other parts of the world. Mr. Maskell, the Registrar of New Zealand, has done more to advance the study of the Coccidæ than any other student, and his works should be available to every worker. In Australia, Dr. Froggatt and Mr. French are authorities for certain sections of the group. And Mr. E. Ernest Green is now preparing an elaborate work on the Ceylonese species. England can boast in having, as a pioneer in this difficult study, no less an authority than the veteran entomologist, Mr. J. W. Douglas, to whom the writer owes many debts of gratitude for hints ungrudgingly given during the last nine years that he has devoted to the study of these pests. It will be seen, therefore, that the "British authorities" are not "a little behind," but well advanced in the study, and can take equal rank with their fellow workers in other parts of the world.

The species submitted for identification is the *Mytilaspis pomorum*, B., or "Mussel Scale," which in the writer's practical experience as a fruit-grower, is much more frequently found upon the Apple. It is also fond of the Cotoneaster, and occurs also upon Currant, Raspberry, Hawthorn, Broom, Wild Rose, Vaccinium, Gorse, and common Heath (*Erica*). The writer has also met with it on Cassia under glass. It will be seen, therefore, the species is a very general feeder, and by no means peculiar to the Pear-tree."

COLONIAL NOTES.

NEW ZEALAND.

WE have been away for a month in the interior to see the Alpine plants at home, and to get photos of them *in situ* for a book we are preparing on the Alpine flora. We have been much struck with the beauty of the alpine *Senecio* Lyalli and its varieties, and we think they rank next to *Ranunculus* Lyalli. We have tried to bring them into cultivation in our nursery, but have hitherto failed owing to the heat of our summers. Seeds of these *Senecios* are rarely fertile, and this may be said of many of our Compositæ. With regard to *Aciphylla*, we find them very bad seeders. The plant is dioecious, having male flowers on one plant, female on another. The male plants are disappearing, and this accounts for the imperfect state of the seed. To all appearances the seed is good when ripe, heavy, and full of albumen, but 90 per cent. of it has never been fertilised.

Many of our New Zealand seeds take two or three years to germinate, *Clematis indivisa* is an example. The first year there is no sign of a plant; the second year 1 per cent. will come up; but if the pan is left in a cold frame undisturbed, every seed will germinate the third year. We never throw away our seeds till after the third year.

On the receipt of plants from New Zealand, they should be potted singly, and kept in cold frames till 12 or 18 inches high before they are planted out on a north border. The border should be prepared with peat and rough sandstone; plant the roots 3 inches deep with crowns inclining upwards, and let them alone. Any coddling treatment will kill them. A perforated pipe running at the back of the border (which should slope to the front) will enable the grower to keep them constantly wet during the heat of your summer. But, after the blooming period the supply must be cut off, or you will get no bloom the next season. *Adams & Son, Christchurch.*

CEYLON BOTANIC GARDENS.

The report for 1897 of the Director (Mr. J. C. Willis) of the Royal Botanic Gardens, Ceylon, is now before us. Among the work undertaken was the

introduction of new and important economic plants and experiments in cultivation. The director reports that: "A large amount of ground has been laid out during the year in experimental plots of economic plants, chiefly at Peradeniya. The labour required for this work has been provided partly by discontinuing the sale of common pot-plants for verandahs, partly by neglecting the ordinary work of the gardens, such as weeding, &c. An increased vote for labour has, I am glad to report, been sanctioned for 1898, the increase amounting to Rs. 1,150. The whole of this labour will be devoted to experimental work. Money has also been voted to provide the salary of an efficient native officer to supervise this work, under the immediate direction of the European officers." We further read that: "The completion of the late director's *Flora of Ceylon* has been undertaken by Sir Joseph Hooker."

"A large amount of time and labour has been expended in the study of the Cacao disease; and various diseases of Tea, Cocoa-nuts, Betel, Nutmeg, and other plants have also been studied by the Director and the Honorary Entomologist." Among the notes on economic plants, we find the following relating to Tea, Coffee, and rubber:—

Tea.—The total export is again the largest on record, exceeding 116,000,000 lb., an increase of 8,000,000 lb. over 1896. Exchange has continued high, and prices rather low (7'71d., against 8'21d. in 1896). The immense area now covered with Tea still remains singularly free from disease, but great care and attention must be exercised if this condition of things is to last. When an outbreak of any disease apparently due to insects or fungi is noticed, the affected plants should be at once destroyed by fire, to prevent if possible any further spread of the disease. One or two cases have occurred during the year of outbreaks of disease among nurseries of young plants grown from Indian seed. Planters should pay special attention to their nurseries in this respect, as considerable risk is run of importing dangerous and troublesome diseases with foreign seed.

Coffee.—The exports of Coffee barely exceeded 19,000 cwt., over 3,000 less than last year. The planting of Liberian Coffee has received a severe check by the very great fall in price which has occurred during the year.

Rubber.—The interest taken in the cultivation of Para rubber has received a very great impetus during the year, and the demand for seed has been enormously larger than the supply. These gardens form practically the only source of seed from mature trees. The total crop this year was rather over 100,000 seeds, of which 88,500 were sold to planters in Ceylon."

The extracts give some idea of the important work undertaken at this station, and of the energy with which it is carried on.

A SCHOOL OF HORTICULTURE IN NOVA SCOTIA.

Professor Sears, in the Report to the Secretary for Agriculture, gives an account of this school. There are fifty-five regular students, two of whom are from England. The instruction afforded includes the propagation of plants, seeding, budding, grafting, &c.; principles of pruning for wood or for fruit, pruning at different times of the year, and special pruning applied to different fruits; spraying of plants for both insect and fungous pests; choice of fruit, fruit-growing, tillage, planting, harvesting, marketing, packing, &c.

GARDEN PICTURES AND LANDSCAPES AT THE NEW GALLERY.

GARDEN pictures and landscapes are rather numerous, and form a decided feature in this season's exhibition at the New Gallery, and in some cases as parts of *genre* pictures, as in the case of Walter Maclaren's "The Balmy Gale from Hill and Dale," which give us besides excellent figure drawing and colouring. Worthy of note by lovers of rustic subjects, mention may be made of a landscape by James Charles, showing feeling for colour and detail in the group of Elms stripped, truly, in the barbarous fashion too often to be seen about to

suburbs, their fresh early summer greenery, however, contrasting well with the varied tones of the bit of copse at their foot.

The New Forest affords, as it needs must, abundant food for the artist, and "End of Autumn," by F. Golden Short, No. 28, depicting a glade with Oaks in the fall of the leaf is excellent; whilst No. 23, by Camille Vernede, affords us Oaks in their summer-attire, also excellently rendered. Arthur Lucas' "Cuckfield," which is the church on the hill at that village, is taken at a time of day when the sunlit building afforded the greatest contrast with the dark

hither and thither at all sorts of angles, but all very pretty notwithstanding, as we behold the orchard on this sunny May morning. We wonder if the owner has taken similar precautions against the "Worm i' the Bud," the dreaded winter Moth that may play sad havoc with the crop. At any rate, no grease-bands were visible on the stems. The "Pool," by James E. Grace, although consisting of but a few Birches, is the work of one who is possessed of the true artistic spirit. In Herbert A. Olivier's "A Garland Greeting," we seem to be transported to ancient Greece, excepting for the dresses

cliff, and yellowish-orange and bronzy hues of wild vegetation in the immediate foreground; and these two features, with the blue of the sea in the middle distance, make a successful whole. Arthur Lucas' "In a Garden," and Alfred Parsons' "Larkspurs and Roses" will find admirers, although utterly dissimilar in subject and treatment. Small floral pictures, consisting of Roses, Azaleas, Japan Anemones, Irises, Chrysanthemums, Carnations and Love-in-a-Mist, were remarked, of which it must be said they were in all cases truthfully and carefully drawn, and prettily posed—no pun being intended here.

FIG. 100.—MEMORIAL GROUP OF PLANTS INTRODUCED BY THE LATE J. LINDEN, AT THE GHENT QUINQUENNIAL EXHIBITION.

(From a photograph by B. Jacobs & Cie., Ghent.)

mass of Scots firs adjoining. In "Sweet Williams," by Alfred Parsons, a capital use is made of a thick row of these plants in most abundant bloom on either side of a cottage-garden path. We should say to gardeners by profession "Please note," for you now seldom make all the use you might of this beauty among Dianthi. The back of the borders is filled in with the tall soft-yellow flower-spikes of the Evening Primrose, *Oenothera biennis*. The "Back of the Village," by the same artist, is like many another views in a South country and Midland village, an instance of abundant blossoming Apple-trees, not planted in straight lines or consisting of straight perpendicular stems, standing at a given distance apart, as we are advised in these days of American competition to plant our trees, but irregularly, leaning

of the young women, which seem decidedly modern, and the question involuntarily arises, how are we to fit in this kind of floral compliment with present-day ideas? The effect of the setting sun's rays lighting up the boles of the Fir-trees on the hill to the right-hand side of the figures, and also irradiating the prettiest one of the band of young women, is rather startling, and almost equivalent in its strained effect to limelight on a theatrical stage. The trees, herbage, and water in this picture are managed with happy effect. "A Pool on the River," by J. Clayton Adams, shows the still water of a shallow, with trees very naturally disposed, and over all a partially clouded sky—a pleasant scene, excellently drawn and painted.

John Finnie's "Runswick Bay" is part sea, part landscape, with, as a distant background of sunlit rocky

BOOK NOTICE.

HARDY HAWTHORNS.

THE Copenhagen Botanic Garden has long been noted for its collection of species and varieties of the genus *Crataegus*, and Mr. J. Lange, formerly Director of the garden, has done good service by publishing a descriptive illustrated monograph* of the forms there cultivated. It is written in Danish and Latin, and the plates are beautifully executed, and sufficiently coloured for all practical purposes. Mr. Lange is an authority on this genus, and it is hardly

Revisio Specierum Generis Crataegi, imprimi curam quo in Hortis Danicæ coluntur. Copenhagen, 1897. 8vo, pp. 106, with ten partially-coloured plates.

necessary to add that the descriptive part is highly critical; but what is more, it is singularly clear and intelligible. The species figured are:—*C. intricata*, Lge.; *C. sorbifolia*, Lge.; *C. Celsiana*, Bosc.; *C. pinnatifida*, Bunge.; *C. pinnatiloba*, Lge.; *C. altaica*, Ledeb.; *C. polyacantha*, Jan.; *C. orientalis*, Pall.; *C. tanacetifolia*, Pers.; *C. macracantha*, Loud.; *C. succulenta*, Schrad.; *C. hiemalis*, Lge.; and *C. Dippeliana*, Lge. For purposes of classification, Mr. Lange makes use of the direction of the lowermost pair of lateral nerves of the leaves, the presence or absence of hairs on the fully-developed leaves, deciduous or persistent stipules, and the colour of the fruit. Altogether forty-eight species are described, including several of unknown origin. I may add that the classification is purely artificial, as may be gathered from the fact that *C. oxyacantha* and *C. monogyna* are widely separated. *W. B. H.*

TREES AND SHRUBS.

MAGNOLIA CONSPICUA.

A REMARKABLY fine specimen of this pretty Chinese species is now in flower at Woking in the nursery of Mr. W. C. Slocock, and as it is from 25 to 30 feet in height, it presents quite a striking feature, being literally covered with its pure white flowers, which are sometimes suffused with purple. As the plant is sheltered by large trees, the frosts of the past few days have not injured it. The age of this specimen must be more than seventy years, for an old inhabitant of Woking assures me that he can recollect it sixty years ago. Another fine specimen of *Magnolia grandiflora*, Exmouth variety, can be seen in the same nursery growing on a wall of a house, which, although not yet in flower, will present a grand sight during July and August.

Magnolia Soulangeana, the supposed natural hybrid between *Magnolia conspicua* and *Magnolia obovata*, with white flowers tinted purple on the exterior, is probably the hardiest *Magnolia* in this country, and several fine specimens, averaging from 12 to 15 feet high, and several yards through, are growing in St. John's, Woking. Specimens of *Magnolia Lenne*, with rose-coloured flowers, is another distinct variety, the result of crossing *M. conspicua* and *M. obovata*, var. *discolor*. *M. stellata*, syn. *Halleana* is another plant that is well worth growing, and flowers very freely at Woking; it has pure white flowers, is of Japanese origin, introduced to this country in 1878. *Magnolias* thrive in the deep sandy-soil of Woking; but in exposed situations, and cold soils, slight protection is needed in the spring months. *E. S., Woking.*

THE WEEK'S WORK.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts

Pines.—When suckers from the old stools have grown to the required size, it will be necessary to detach them and trim the base of each with a sharp knife. Take off a few of the lower leaves and pot the sucker firmly into 6-inch or 8-inch pots, using fibrous soil from which the fine particles have been shaken out. Any suckers that were potted early in the season may now be shifted, before they become pot-bound, into the pots in which the plants will fruit. Leave a space of 2 inches for affording water in sufficient quantity, and when the potting is completed plunge the plants in a bottom-heat of about 85°. Plants that were potted some time ago, but were only partially plunged, owing to a possibility that the heat would increase beyond a safe point, should now be given attention in the direction of adding more tan, or firmly pressing round the pots that which was previously provided. If there is not sufficient tan to cover the pots to the rim, add a little now to the surface rather than disturb the plants by lifting them out. Examine once a week all plants that are rooting freely, and after testing them for dryness by rapping the pots, give sufficient to those that need water to thoroughly moisten the soil in each case. If any shading is used, it should be very slight, and only

during the hottest part of bright days. The temperatures may range from 70° at night to 75° during dull days, allowing a rise of 5° to 10° when the house is closed for the day; and by closing early, less fire-heat will be necessary through the night. Afford ventilation with care, and gradually commencing before the temperature rises above 75°. Plants with swelling fruit may be kept a little warmer than the above temperatures, and all the gills should be removed from the base of the fruits. Remove any suckers that show on growing plants, and in the case of fruiting-plants leave one or two only at the base. Spray the plants with the syringe on fine days, at closing time; but at other times, damp the floor, walls, and the tan-bed between the plants. When damping between plants with fruit swelling, direct some of the water to the lower leaves so as to nourish the roots in the axil.

Melons.—Plants upon which the fruits are colouring may be kept rather dryer at the root than formerly, and plenty of air should be afforded. The fruit is fit for cutting from the plant when the stalk shows signs of parting from the rind. Give plenty of water to plants with swelling fruits, and occasionally add some manure to the water. When syringing take care to do it thoroughly, so as to prevent red-spider. They are more liable to canker at this stage than at any other. If the stem immediately above the soil shows the least indication of canker, apply freshly-slaked lime round the part. Plants just coming into bloom will need attention in regard to setting the flowers; no syringing should be done at this time, but a somewhat dry atmosphere maintained. The house may be damped once each day, in the afternoon. Put out succession plants before they suffer check from becoming pot-bound, or failing present accommodation, afford them a large shift. Another sowing of seed should be made at this date.

Cucumber seed may be sown. When the roots of the older plants have permeated the last layer of soil that was given, add another layer of the same kind and quantity. Frequently attend to stopping and tying. Afford water copiously whenever the soil shows signs of dryness, occasionally substituting manure-water, and for a change use some well-proved concentrated manure. Syringe twice on fine days, and once if the weather be dull. Do not allow the fruits to remain on the plants when they are fit to be cut.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Hippeastrums.—Plants whose flowering is past, should be encouraged to make growth by placing them in full light, plunging the pots in some moisture-holding material in a house or pit, and afforded good warmth and free ventilation in fine weather, soot-water and other weak stimulants being supplied occasionally. Bulbs that may be at rest should now be shaken out and repotted, as any further delay in starting them into growth hinders proper development, and the thorough ripening of the bulbs.

Centropogon Lucyanus.—If young plants are required, take lateral shoots 2 inches in length, and after trimming insert them in 5 or 6-inch pots filled with sandy soil round the edges of the pots. Cuttings of this plant root freely if put on a moderately dry shelf and shaded from the sun. The old plants may be cut back and repotted after shaking out a large proportion of the exhausted soil, and once the plants start to grow, afford them intermediate-house temperature.

Begonia Weltoniensis.—Cuttings of this variety should now be inserted in light sandy soil in 3-inch pots, and struck on bottom heat in a frame or in the propagating-pit, shading them carefully from the sun till rooted. As plants of *Begonia manicata* go out of flower, cuttings may also be struck, and if a large increase of the stock is desired, the stems may be cut into lengths of two or three joints each, and inserted singly in small pots. Make cuttings of *Begonia Gloire de Sceaux*, and similar varieties when these are obtainable, plunging the cutting pots in cocoanut-fibre on bottom-heat of 80°; affording water to settle the soil, and keeping them close. Repeated applications of water is apt to rot them.

Justicia flavicoma.—If strong cuttings are plentiful an increase may now be made, placing them to the number of five in a 60, or one in a thumb. Cuttings soon make roots if they are kept moist and shaded in a close hot-bed frame or under a hand-light. The old plants should be cut closely back, and when they break shaken out partially, and repotted in the same

sized pots. Young are preferable to old plants, growing with more vigour and being less liable to infestation by brown scale.

Greenhouse Rhododendrons.—Some varieties of these plants, as for example, *Lady Alice Fitzwilliam*, make straggling growth and become unsightly; these may, after being cut hard in, be placed in a genial moist atmosphere, where they will push buds freely from the old wood, and in two years will form shapely plants. The young growths of these species and varieties are impatient of strong sunshine, and must be slightly shaded from it.

Stephanotis floribunda.—Plants that were placed in heat early in the season will be showing trusses of flowers, and a considerable amount of growth, which should not be allowed to grow at will, but be kept tied in as it progresses. If mealy-bug be present let the plants be cleared of it before the trusses open, it being a difficult matter, and damaging to the flowers to do this afterwards. Manure-water in a weak state should be frequently applied to the plant when in active growth, and air freely afforded in the warmest part of the day when the weather is favourable.

HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Fruit-trees on Walls.—The present year has been hitherto exceptionally dry, and the deficiency of rain since January 1, according to returns from the Meteorological Office, amounts to more than 3 inches below the average in many parts of England; the showers that have fallen were light, and incapable of penetrating deeply into the soil. The snowfall has been very light in most parts of England, and the consequent deficiency of moisture is likely to make itself felt by wall fruit-trees especially, less moisture reaching them than trees in the open quarter. The trees on the eastern aspect are liable to suffer greatly, the greater part of our rainfall coming from west and south-west. Under these circumstances, the fruit-tree border should now be afforded a thorough application of clear water, or if liquid-manure be obtainable, this would be preferable, but it must be well diluted if rank and strong. If the soil has caked on the surface, let it be loosened with a digging-fork, so as to allow the water to penetrate in every part; and a few days after the water has been applied, the ground may be stirred with a Dutch-hoe to loosen the soil and give a crumbly surface, and thus act in the nature of a mulch in preventing rapid evaporation, and a light dressing of short manure will be useful in this respect. All kinds of fruit trees and bushes fruit will be benefited by water at this season, especially trees which have numerous flowers open, and failing this many of the flowers are sure to fall off.

Apricots.—In warm districts the foliage of these will now be sufficiently advanced to afford protection to the fruit, rendering fish-netting and other protective means unnecessary. Their removal is advisable, as their retention would render the leaves tender, and liable to burn during bright sunshine. Those Apricot-trees which have set a good crop of fruit may now have the latter thinned, taking off all the smaller fruits, and leaving others at 3 inches apart. It is as well to do this early, as exhaustion of the tree is thus prevented, and the grower is enabled to secure a good crop every year, large quantities of carbonate of lime and other substances being drawn from the soil, only to be thrown away afterwards if thinning be left till stoning has taken place; the growth of the tree is also weakened owing to the heavy crop of fruit that has to be taken afterwards in order to recuperate. A small, green kind of maggot (*Ditula angustiorana*) frequently attacks Apricot-leaves at this stage, doing much damage by eating them, and if left undisturbed for a few seasons it increases fast, and will then completely denude the trees. The grubs should be collected and killed.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

East Indian-house.—*Bolles*, *Pescatorias*, *Warscewiczellas*, *Huntleyas*, and *Batemannias* are now growing and rooting freely. These plants succeed well in pots or baskets, and in a soil consisting of peat and sphagnum-moss, using rather more moss than peat. Afford plenty of drainage, and when repotting keep the plants well above the rim of the pot. Healthy established plants that do not need to be moved may be resurfaced with heads of living moss. The plants should be placed in the coolest position

available in the East Indian-house, and be always shaded from the least degree of bright sunshine. In order to keep their surroundings continually moist, stand the plants upon a layer of sphagnum-moss upon a stage. Throughout the summer spray the foliage over lightly two or three times a day, and afford root waterings as often as may be necessary. Protect the plants from a dry current of air, or insect pests will attack them. *Calanthe veratrifolia* fast developing its flower-spikes must be kept free from green-fly, and in the case of small weakly plants, it will be better to remove the flower-spikes as soon as they appear.

Calanthes.—The deciduous *Calanthes* that were potted several weeks ago, are now rooting from the new growths, but it is necessary to advise beginners against over-watering the plants. Examine the most forward plants occasionally, and if the soil is found to be dry sprinkle the surface with tepid rain-water from a fine-rose can. As the plants become better established they may be afforded more water, and damp the sides of the pots morning and evening.

Cattleyas.—Plants of *Cattleya Trianaei*, *C. Gaskelliana*, *C. exoniensis*, *C. amethystoglossa*, *C. Scho-*

up flower-spikes, will require a little more water at the root until the flowers are fully developed; *C. Bowringiana* being at rest should be afforded water only at long intervals of time. Until growth commences a cool position in the house is necessary. The distinct *C. Walkeriana* is now producing flowers from the short slender shoots which issue from the base of the last-made pseudo-bulb, it should be suspended near to the roof-glass, and where it may obtain plenty of sunlight throughout its growing period.

Various Species.—*Lælia Lindleyana* should also be suspended to the roof-glass of this house, but a rather shady position is preferable. Should it be necessary, the plant may now be supplied with fresh potting material. In the intermediate-house the elegant-flowering *Platyclinis filiformis* is now starting to grow, and will require a more generous treatment. Suspend the plant in a moist shady corner of the house, and afford plenty of water at the root; an occasional syringing of the foliage with tepid rain-water will encourage the young growths and flower-spikes, and at the same time keep the foliage luxuriant and free from insect pests. Plants of the pretty *Oncidium ornithorrhynchum* and its variety *album*, which are

then set out the prepared plants in two rows in each trench, allowing 6 inches for dwarf, and 9 inches for the stronger varieties, from plant to plant. Seedlings growing in frames require much air in fine weather, otherwise they will become weak and stunted; overcrowding must also be avoided, which cannot, however, occur if the plants were pricked-out 4 inches apart.

Turnips.—Make sowings of Turnip-seed at fortnightly intervals till the middle of August, sowing thinly in drills hardly 1 inch deep, and drawn at 18 inches apart, and let the plants be thinned in good time to a distance of 6 inches apart, and eventually, as regards later sowing, that do not bolt so soon as early ones, to 1 foot apart. Pay particular attention to the early sowings, the Turnip-fly or beetle being very prevalent in seasons like the present. If the ground be dry, afford water to the drills before sowing, and again when the young plants are about to be thinned, if no rain fall. Dust the plants with fresh soot, or soot and wood-ashes in the early morning as a precaution against the fly. Excellent varieties will be found in Dobbie's Model, White Stone, Chirk Castle, and Veitch's Red Globe—the last two for late use; and of yellow Turnips, Golden Ball and Sutton's Yellow Perfection.

Maize or Indian Corn.—Sow the seeds singly in pots in loamy soil, and place in a temperature of 50°, choosing the varieties Extra Early Tom Thumb, Crosby's Early Sugar, or Moore's Early Concord, and grow them on under glass till the end of the month of May, when, being hardened off, they may be planted 2 feet apart in a warm part of the garden. It does no harm to Maize to remove some of the leafage if it be very abundant. During hot weather water is beneficial. For cooking, the culms should be gathered when of full size, and the enveloping sheath still quite green.

Sorrel.—Remove the flower-stalks as they appear, and thin out seedling plants.

Savoy.—Seeds may be sown again of Drumhead, Dwarf Green Curled, and others, for winter supplies.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Herbaceous Perennial Borders.—Most of the plants having by this time appeared above the soil, let it be afforded a good soaking with clear water, unless rain fall heavily, the soil having become very dry, and the surface caked. The day following, the border should be hoed, then in the intervening spaces sow such summer annuals as Sweet Peas, Mignonette, Candytuft, *Linum grandiflorum*, *Nemophila* in variety, *Godetias*, &c., which have a good effect, and form a carpet or ground-work to the taller-growing plants. The weaker shoots of Delphiniums, Phloxes, and others, should be removed from the stools in order to strengthen those that remain. Sow at wide intervals at the back of the borders, seeds of the tall Sunflowers, and in the front the dwarf variety, these being very effective plants in the early autumn. Lily-bulbs may still be planted.

Bedding Begonias.—The tubers of these plants, if they were placed in a mild warmth as advised, will now be in a fit condition for potting or planting-out in frames. If the latter method has, from necessity, to be done, the tubers should be planted about 1 foot apart in a mixture of leaf-mould, sand, and decayed manure, keeping the frames close for a week or two until the roots have begun to penetrate the soil; then gradually admit air on fine days, thoroughly hardening them off before planting-out, and affording a spraying with a fine-rose water-can in the afternoon if the day is warm. The plants from seed sown in February last, being now of a good size, should be kept growing, potting them as they require it, and taking great care not to afford water very freely or the soil may become sour.

General Remarks.—Afford newly-planted shrubs and trees abundant root watering, and spray the tops on warm evenings. Newly-planted Rhododendrons, and all other American plants, should receive particular attention in this respect, east winds having dried up the moisture in the soil to an excessive degree. Take note of any early spring-flowering subjects requiring to be shifted in the autumn, as it is only by paying attention to these details at the different seasons that the planting of a garden can be so managed as to afford gratifying effects at all seasons.

Auriculas now, or just about to come into flower, should be afforded water, and the ground around them mulched with cocoa-nut fibre refuse.

FIG. 101 — BEDS OF DWARF AZALEAS IN THE ANNEXE, GHENT.

(From a photograph by B. Jacobs & Cie., Ghent.)

fieldiana, the autumn-flowering *labiata*, and the different varieties of *Lælia elegans*, are either commencing to root from the last made pseudo-bulbs, or sound breaks are pushing from which new roots will shortly appear. Such plants may, if they need more root-room, be safely repotted, as the young roots will quickly establish themselves in the new material. The compost should consist of good fibrous peat and sphagnum-moss in equal proportions, freely mixing with it some thick crocks or bits of charcoal. Avoid using pots larger than the plants require. Keep the plants well above the pots, and use sufficient stakes to hold them firmly in their places. Pot moderately firmly, but not so hard as to prevent the water from passing rapidly through the compost. The pots should be three parts filled with drainage materials, over which it is usual to place a layer of sphagnum-moss. When the plants have been repotted, stand them in a moist shady part of the Cattleya-house, and for a few weeks keep the compost rather on the dry side. *C. Lawrenceana*, when it has finished flowering, should be kept comparatively dry. Immediately that root-action has commenced, the plants may be repotted. The sweet-scented *C. Schroderæ* is also in bloom, and when the flowers fade it will require identical treatment. *C. Mossiae*, *C. Mendelii*, *C. Schilleriana*, *C. Skinneri*, *C. Warneri*, *Lælia purpurata*, *L. tenebrosa*, and the various congeneric hybrids that are sending

now in full growth, will require plenty of root-moisture until growth is completed. A cool shady position in the intermediate-house is the best place for them.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Asparagus.—The keen frosts which have frequently occurred of late damaged many of the heads as they were coming through the ground where no protection was afforded with bracken, clean straw, &c. To prevent future loss from this cause, let the beds be examined daily, cutting all heads that range from 3 to 4 inches above-ground. Flower-pots (48's), with the hole plugged with a bit of clay, offer good protection, and are easily applied, covering one, two, three, or more heads under each.

Celery.—In order to have fine heads of early Celery, the trenches should be prepared betimes, affording a space of 4 feet from centre to centre, and making them 2 feet wide, and 9 inches in depth. Manure in a half-decayed state must be freely used, i.e., the trenches may be half-filled, and just burying it by digging, if the lower stratum of soil be of good quality; otherwise, shovelling soil from the sides of the trenches for this purpose. Before planting, allow the stuff to settle somewhat,

APPOINTMENTS FOR MAY.

TUESDAY,	MAY 8	Scottish Horticultural Association, Meeting.
THURSDAY,	MAY 5	Linnean Society, Meeting.
FRIDAY,	MAY 6	Royal Botanic Society, Lecture.
SATURDAY,	MAY 7	Royal Botanic Society, General Meeting.
TUESDAY,	MAY 10	Royal Horticultural Society's Committee, Somersetshire Agricultural Society, Show at Weston (3 days).
FRIDAY,	MAY 13	Royal Botanic Society, Lecture.
MONDAY,	MAY 16	Devon County Agricultural, Show at Newton Abbot.
WEDNESDAY,	MAY 18	York Florists' Exhibition.
FRIDAY,	MAY 20	Royal Botanic Society, Lecture.
SATURDAY,	MAY 21	Royal Botanic Society, General Meeting.
TUESDAY,	MAY 24	Linnean Society (Anniversary).
WEDNESDAY,	MAY 25	Royal Horticultural Society's Show in the Temple Gardens (3 days). Bath and West of England and Southern Counties Society's Exhibition at Cardiff (5 days).
FRIDAY,	MAY 27	Royal Botanic Society, Lecture.

SALES FOR THE ENSUING WEEK.

MONDAY,	MAY 2	Clearance sale of Plants, Horses, Carts, Furniture, Greenhouses, Piping, &c., at the Pond Lane Nursery, Clapton, by Protheroe & Morris.
TUESDAY,	MAY 3	Greenhouse Plants, Hardy Perennials, Calceolarias, Gladioli, &c., at Protheroe & Morris' Rooms.
WEDNESDAY,	MAY 4	Japanese Lilies, Palms, Carnations, Gladioli, Bedding Plants, &c., at Protheroe & Morris' Rooms. Palms, Border Plants, Bulbs, &c., at Stevens' Rooms.
FRIDAY,	MAY 6	Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—51° 7°.

ACTUAL TEMPERATURES:—

LONDON.—April 27 (6 P.M.): Max., 59°; Min., 50°.

PROVINCES.—April 26 (6 P.M.): Max., 56°, Eastern Counties; Min., 43°, Aberdeen.

Mild, light rain; thunder in places.

The Feeding of Plants.

AMONG the most remarkable exhibits at Ghent was a series of plants grown under the influence of certain manures, and varying in composition according to the particular plant. The composition of the manures is deduced from the analyses of many hundreds of plants, and we believe these analyses, probably, far the most numerous ever undertaken in the case of garden-plants, will shortly be published in full. The manure has the form of a fine powder enclosed within a metallic-wrapper, and firmly compressed into the shape of a cartouche or capsule, cylindrical in form, about $\frac{3}{4}$ inch across, and $\frac{1}{2}$ inch in depth (fig. 102). It is simply thrust into the soil of the pot to a depth of $\frac{1}{2}$ or 1 inch, and allowed to remain. After a time it is found that the fertiliser gradually disappears, and at length nothing is left but the little pill box-like wrapper, which originally contained the mixed fertilising-powder.

The results, as shown, were certainly remarkable. Two plants of each kind that had been thus fed were shown one on either side of a plant of the same age, which had received no dose of fertilising-powder, and the difference in such case was very noticeable.

The main feature of these experiments consists in the separate analysis of each plant, so that the manure applied is compounded according to the composition of the plant itself. It may be objected that one analysis of each plant is not sufficient to furnish any accurate basis. The analyses, however numerous, only give the composition of the dead plant at the time the analysis was made. This is a matter of prac-

tical moment, because the requirements of the plant during the growth of the vegetative organs may be, and are, different from those experienced by the plant during the production of flower, and, still more, of reserve matters in the seed.

Another feature of the experiments is the slow and gradual way in which the fertiliser is made to act. The moisture of the soil penetrates slowly and gradually between the folds of the wrapper, and the plant thus gets the benefit of rich nutritive food, applied gradually, and consumed slowly. It is not the first time we have had the opportunity of referring to M. TRUFFAUT's experiments, and they were described by Mr. GEORGE L. PAUL in our number for October 23, 1897, p. 284. At Ghent, the experiments were shown, so that those who ran might read. It is obvious, however, that a more leisurely examination of the results would be amply repaid. For the following details we are indebted to M. TRUFFAUT:—

Anthemis.—The plants shown by M. Truffaut were struck from cuttings made on January 5, 1898. One kilogramme of *Anthemis* contains 3.10 grammes of nitrogen, 0.26 gr. of phosphoric acid, 2.35 gr. of potash, and we applied to them a fertiliser containing 13.4 per cent. of nitrogen, 8 per cent. of phosphoric acid, and 7.20 per cent. of potash, by means of two metallic capsules. The treatment commenced on February 20, 1898.

Asparagus tenuissimus.—The plants exhibited were raised from cuttings made last September. One kilo. of *Asparagus* contains 5.44 gr. of nitrogen, 2.09 gr. of phosphoric acid, 5.09 gr. of potash. The manure

FIG. 102.—M. TRUFFAUT'S ARTIFICIAL MANURE CARTRIDGE.

applied consisted of 13.4 per cent. of nitrogen, 8 per cent. of phosphoric acid, and 5.80 per cent. of potash, contained in two capsules. The treatment commenced on January 15, 1898.

Calceolaria.—These were raised from seed. One kilo. of *Calceolaria* contains 1.73 gr. of nitrogen, 0.26 gr. of phosphoric acid, and 2.85 gr. of potash; we therefore used a manure consisting of 7.20 per cent. of nitrogen, 9 per cent. of phosphoric acid, and 7 per cent. of potash, in 3 cartridges or capsules of 6 grammes. The treatment commenced Feb. 15, 1898.

Corypha australis.—The treatment of the plants began in July, 1897. One kilo. of *Corypha* containing 4.39 gr. of nitrogen, 0.73 of phosphoric acid, 1.80 gr. of potash. The manure applied contained 10.20 per cent. of nitrogen, 7 per cent. of phosphoric acid, and 5.80 per cent. of potash in 4 capsules.

Cocos Weddelliana.—The treatment of the plants commenced in November, 1897. One kilo. of *Cocos* containing 5.79 gr. of nitrogen, 0.34 gr. of phosphoric acid, and 5.5 gr. of potash. The manure applied contained 10 per cent. of nitrogen, 7 per cent. of phosphoric acid, 5 per cent. of potash, in 2 capsules of 6 grammes.

Dracena Baptisti.—The plants were raised from cuttings taken in December, 1897. The treatment commenced March 1, 1898. One kilo. of *Dracena* contains 3.14 gr. of nitrogen, 0.07 gr. of phosphoric acid, and 3.32 gr. of potash. We applied, therefore, manure consisting of 9.45 per cent. of nitrogen, 3.80 per cent. of phosphoric acid, 7.65 per cent. of potash in two capsules of 6 grammes.

Elargonium.—The plants were raised from cuttings made in October, 1897. Treatment was begun March 1, 1898. One kilo. of *Elargonium* contains 3.50 gr. of nitrogen, 3.27 gr. of phosphoric acid, 2.74 gr. of potash. We applied manure containing

8.60 per cent. of nitrogen, 8.60 per cent. of phosphoric acid, and 8 per cent. of potash in two capsules of 6 grammes.

Hortensia.—The plants were raised from cuttings made in June, 1897. Treatment commenced February 20, 1898. One kilo. of *Hortensia* contains 7 gr. of nitrogen, 1.48 gr. of phosphoric acid, and 3.35 gr. of potash. We applied 11.5 per cent. of nitrogen, phosphoric acid (quantity obliterated), and 5.9 per cent. of potash in three capsules of 6 grammes.

Kentia Belmoreana.—Treatment commenced June 10, 1897. One kilo. of *Kentia* contains 2.92 gr. nitrogen, 0.47 gr. phosphoric acid, and 1.44 gr. of potash. We applied 12 per cent. of nitrogen, 7 per cent. of phosphoric acid, and 5.80 per cent. of potash in four capsules of 6 grammes.

Pandanus.—The treatment of the plants shown began June 10, 1897. One kilo. of *Pandanus* contains 2.26 gr. of nitrogen, 0.40 gr. of phosphoric acid, and 1.37 gr. of potash. We applied a mixture containing 10 per cent. of nitrogen, 7 per cent. of phosphoric acid, 5.80 per cent. of potash, in four capsules of 6 grammes.

Puris Wimselli.—Treatment began February 25, 1898. One kilo. of *Pteris* contains 2.27 gr. of nitrogen, 0.22 gr. of phosphoric acid, and 1.32 gr. of potash. We applied a mixture containing 9.40 per cent. of nitrogen, 3.80 per cent. of phosphoric acid, and 7.50 per cent. of potash, in two capsules of 6 grammes.

Results.—1. In no case did the use of manures give unfavourable results. 2. As a general rule, the plants treated are greener, and have firmer tissues, and a more abundant and earlier blooming season than have others not treated.

GHEENT EXHIBITION.—In our last issue we were enabled to give illustrations of almost all the "New Plants" exhibited on this occasion. To-day we give representations of three of the most important groups, full descriptions of which were given in our report last week.

LINNEAN SOCIETY.—The next meeting of the Society will be held on Thursday, May 5, at 8 P.M., when the following papers will be read:—Sir JOHN LUBBOCK, Bart., M.P., F.R.S., on some "Spitzbergen Collembola." Miss ETHEL BARTON, on the "Structure and development of Soranthera." Mr. J. T. CUNNINGHAM, "The species, the sex, and the individual."

EXHIBITION AT LYONS.—The town of Lyons has decided to organise an international horticultural exhibition, to be opened on September 1 of this year. M. ANTOINE RIVOIRE is the President, M. CONSANÇAT is Secretary, and M. ROZAIN-BOUCHARLAT is the Assistant-Secretary.

RATING OF NURSERIES IN IRELAND.—At a meeting of the Council of the Royal Horticultural Society of Ireland on April 14, the following resolution was adopted:—"That this Council of the Royal Horticultural Society of Ireland desire to urge on the City and County of Dublin Parliamentary representatives to endeavour to alter the proposed Local Government Bill to the extent of including all agricultural lands in urban districts, as well as rural districts, in the provisions of the Bill. That copies of this resolution be forwarded to the above members of Parliament."

THE SUPERIOR QUALITY OF BRITISH ARTIFICIAL MANURES has triumphed over the attempts of the Franco-Belgian syndicate to close French markets to them. During 1897, the British manures imported into the agricultural district of Cherbourg held their own, and maintained their prices, while the Franco-Belgian firms were selling at a loss, several of the firms breaking down under the strain. The Continental superphosphates in many cases proved unsatisfactory, there being a general complaint of the uneven quality of manures from Germany, Belgium, and the north of France, the percentage of phosphoric acid not being uniform, and could therefore not be depended on. As the use of artificial manures for pasture, Potatoes, and market gardening is gradually extending in the district, an advance may be expected in this branch of British imports. *Pharmaceutical Journal*.

FIG. 103.—GROUP SHOWN BY THE SOCIÉTÉ HORTICOLE GANTOISE, AT THE GHENT QUINQUENNIAL. (SEE P. 250 OF OUR LAST ISSUE.)

(From a photograph by B. Jacobs & Cie., Ghent.)

FLOWERS IN SEASON.—As showing how admirable is *Heuchera sanguinea* when grown in a pot for glasshouse decoration, Mr. PARKS, the gardener at Whittington Hall, Chesterfield, sends a capitally coloured bunch of the blossoms. Whilst making use of this plant in the spring flower-garden, in obedience to the dictum of the late W. INGRAM, of Belvoir Castle, gardeners lose sight of the fact that *Heuchera sanguinea* is an ornament to the greenhouse at this season. The flowers last a long time on the plant, and when cut and placed in water. From Mr. W. A. COOK, head gardener at Compton Bassett, have come flowers of double *Cineraria*, in half-a-dozen shades of colour, the heads globular, with no appearance of a disc, unless the florets are parted so as to disclose. The flowers, at a cursory glance, remind one of the *Globe Amaranth*, and possess equal decorative value. The sender remarks on their usefulness as cut flowers for filling *jardinières* and small vases, and that his best lot was in full beauty in February. Our readers would be glad to know his method of raising and cultivating the variety.

MESSRS. J. VEITCH & SONS, LTD.—It is interesting to note that growing evidently out of the great expansion proceeding in a great business, this eminent firm has recently purchased some 50 acres of land at Feltham, Middlesex, for the varied purposes of their trade. The land hitherto has been purely agricultural. It is of a yellowish loam, chiefly on a bed of sandy gravel, and if in time it becomes a fruit-tree nursery, should produce first-rate stuff. Naturally the occupation of this large portion of land in the parish has aroused much local interest, as it will henceforth need a very large amount of local labour as compared with what was employed upon it previously. Apart from that, a good nursery in a locality seldom fails to excite emulation in gardening, to arouse in it greater interest, and in that way also create greater trade.

SUBSTITUTION BRANCHES.—M. AUGUSTE BOIRIVANT has been studying the changes which occur when the terminal shoot is destroyed, and a lateral one is made to take its place, or takes its place spontaneously. We cannot give the details in this place, but we may say in brief that when a lateral shoot replaces a terminal one, it undergoes modifications of structure and appearance which cause it to resemble more closely the branch it supplants than the branch from which it has proceeded. We trust M. BOIRIVANT will continue his researches, as there are many plants which will not or cannot be induced to form a "leader" when the original one is destroyed. If we knew more of the structure of these plants, *Abies amabilis*, for instance, we might be able to remedy the defect, where now we are unable to do so.

CALCUTTA BOTANICAL GARDENS.—Surgeon-Major D. PRAIN, Curator of the Herbarium, is gazetted Superintendent of the Royal Botanic Garden, Calcutta, of the Lloyd Botanic Garden, Darjeeling, and of *Cinchona* cultivation in Bengal; also Government Quinologist and Director of the Botanical Survey of India, *vice* Sir GEORGE KING retired.

THE GROWTH OF THE CELANDINE.—The period of active growth in the common *Celandine* (*Ficaria ranunculoides*) extends from September to May. During the whole summer the plant is, for the most part, reduced to a certain number of roots, swollen, and attached to a short rhizome. In September, one or more buds develop and yield the leaves, the blades of which then cover the surface of the soil. From the end of December the flower-buds appear and expand in succession until April. Towards the end of February new roots are formed, distended, and filled with nutritive matters, while the old ones are gradually absorbed and wither. In May, the leaves dry up, the new roots entirely replace the old ones, the activity of the plant slackens. In the course of the evolution of the plant, starch is transformed into dextrine, afterwards into non-reducible sugar, under two circumstances—1, in May and June, when activity is lessened, then the transformation stops at non-

reducible sugar, which is kept in reserve; 2, from October, when the reserves have been utilised, but then the non-reducible sugar drawn from amylaceous materials yields, in its turn, glucose, which is immediately assimilable. Matters at this period advance as in other plants with a store of starch. Between the two phases, about the month of August, an inverse transformation proceeds, and part of the sugar is again resolved into starch. Such are the conclusions arrived at by M. LECLEERC DU SABLON, and published in the *Comptes Rendus*.

THE OPENING OF KEW GARDENS.—Appended are the regulations at present in force for the admission of artists and students to the Royal Gardens in the morning prior to the admission of the public. These privileges may be seriously curtailed if the sight-seeing public is admitted at an earlier hour than at present. The first consideration is, of course, the proper maintenance of the garden, and the unfettered performance of the work done in it, practical or scientific; next the interest of students and practical gardeners, last of all the claims of the general public:—

Royal Gardens, Kew.—Regulations for the admittance of artists and others in the forenoon.

"Persons desiring access to the Royal Gardens for the *bona fide* purpose of drawing, sketching, photography, or special study, can obtain a card of admission, available during morning hours, on addressing to the Director a written application, stating the object for which such admission is desired. If the application is approved, the card will be sent by post to the applicant's personal address. The privilege of admission is strictly personal to the holder of the card, and it is not transferable.

"A card of admission cannot be issued to admit a class or a party collectively.

"The Gardens may be entered by persons to whom a card is issued, either by the Victoria Gate, opposite the Kew Gardens Railway Station, or by the private gate adjoining the Curator's office [Kew Green]. The holder of the card must sign his or her name in the book kept for the purpose at the gate-keeper's lodge.

"Admission may be obtained after 6 A.M. from April to October; after 6.30 A.M. in March, and after 8 A.M. in January, February, November, and December.

"The privilege is not, however, available on Sundays, Christmas Day, Good Friday, or Bank Holidays.

"Persons holding cards may draw, sketch, or photograph in the open air during such hours as the Gardens are open to the public. But drawing or photographing in the houses cannot be permitted after noon of each day, nor can it be allowed to interfere with the necessary cultural work of the gardeners.

"The Staff of the Royal Gardens accept no responsibility as regards the custody of drawing, photographic, or other apparatus.

"By Order, Royal Gardens, Kew. April, 1897."

FLOWERS FROM THE RIVIERA.—The Post Office has put an end to the transmission of flowers by sample-post, on the ground, we suppose, that the flowers sent out are not samples. What then are they? They are not merchandise, but consist for the most part of small consignments sent as presents to friends at home. Occasionally they are specimens sent from one botanist to another. To suppose that any material injury is done to British traders is, to our thinking, absurd, for the recipients would not purchase the flowers here even if they could. Now, if sent at all, they must be sent by parcel-post.

SAN JOSÉ SCALE.—The Canadian Parliament has enacted a bill precluding the introduction of nursery stock of any kind from the United States, Japan, Australia, and Havana into the Dominion.

THE SURVEYORS' INSTITUTION.—The next Ordinary General Meeting will be held on Monday, May 2, 1898, when the adjourned discussion on the paper read by Mr. H. M. GRELLIER (Fellow), at the meeting of March 21, entitled "Tithe Rent Charge Recovery," will be resumed; and, should time permit, the discussion on the paper read by Mr. THOMAS BLASHILL (Fellow), at the last meeting, entitled "Lessons from Fire and Panic," will be continued. The chair will be taken at 8 o'clock.

NATIONAL CHRYSANTHEMUM SOCIETY.—The annual report and amended financial statement is to hand, in the form of a pamphlet which contains much information useful to Chrysanthemists. The new rules are now published, and they embrace several important modifications from the older ones. There

are to be four exhibitions during next season, on dates already published. In future the Society would do wisely to drop one or two of its shows, and concentrate its efforts upon the events alone that are of use in furthering the objects of the Society. The September show is usually one of Dahlias and Gladioli; the few Chrysanthemums that are staged always suffer in comparison to the brighter-coloured flowers. It is regrettable that the November show will again clash with a meeting of the committees of the Royal Horticultural Society at the Drill Hall. A list of the Fellows of the Society; of affiliated Societies; and the result of the work of the Classification Committee; together with information respecting the winners of the Society's awards during 1897, are included in the pamphlet.

PUBLICATIONS RECEIVED.—*One and All Gardening*, a popular annual for amateurs, allotment-holders, and working gardeners (Agricultural and Horticultural Association, Agar Street, Strand). This handbook, edited by Mr. E. O. Greening, and including various special articles by proficient writers, is well worth the small cost of 2d., and should be useful to the public, to whom it is addressed.—*Sixty Bedding Designs*, by H. Cannell & Sons, Swanley, Kent. A useful handbook for admirers of formal bedding; as, in addition to the varied designs, it includes lists of the most appropriate plants with which to develop them.—*Durban Botanic Society: Report on Natal Botanic Gardens for 1897*, by J. Medley Wood, Curator. We are pleased to find that this is in every way satisfactory, there having been "no serious losses during the year, and the plants, both in garden and nursery, all that could be desired." The acclimatisation, manuring, and anti-disease experiments made with various plants were carried out with enterprise, and are carefully reported.—From the same source comes the *Report for 1897 of the Colonial Herbarium, Durban*, and this is an equally gratifying record of labour and progress.—*Proceedings and Journal of the Agricultural and Horticultural Society of India*, Oct. to Dec., 1897. This gives a list of plants and of publications interchanged with kindred societies. Also interesting notes on drought, and how to cope with it; and on the history and value of the Orange and the Lemon.—*Bulletin of the Botanical Department, Jamaica*, January, 1898, with an article on Public Gardens and Plantations of Jamaica, Notes on Orchids, and Synoptical List of Ferns.—*Agricultural Journal of the Cape of Good Hope*, March 17, 1898. Noteworthy papers are those on Beet-Sugar Industry in California, Wheat Crops of the World, Weeds and their Destruction, and Orchard Soil Cultivation. Stock Farming Matters are also dealt with.—*Some New Indo-Malayan Orchids*, by G. King and R. Pantling (Calcutta). These reports on various novel species of Malaxideæ, Epidendreæ, Vandææ, Neottieæ, Goodyereæ, and Ophrydeæ are reprinted from the *Journal of the Asiatic Society of Bengal*, and are welcome in their present more accessible form.—*Annual Report of the Secretary for Agriculture, Nova Scotia*, 1897. This publication contains the usual articles on technical subjects, and useful abstracts of reports from the proceedings of affiliated agricultural societies which are thus brought together for comparison and study.—*Transactions of the Massachusetts Horticultural Society for 1897*: The contents include notes of meetings, with papers on "Tropical Horticulture," "Structure and Classification of Mushrooms," "The Chrysanthemum," "Plant Beauty," "Sweet Peas," &c. From the Michigan State Agricultural College Experiment Station, Horticultural Department: *Bulletins No. 151*, Raspberries, Blackberries, and Grapes; *No. 152*, Report South Haven Sub-Station, 1897; and *No. 153*, Vegetable Tests, 1897.—*The Fern Bulletin*, edited by W. N. Clute (Binghamton, N.Y., U.S.A.), Spring (quarterly) part, with well-illustrated papers on "Ferns in the New Jersey Pine Barrens," "Bulbets of *Lycopodium lucidulum*, *Equisetum scirpoides*," "*Pellaea atropurpurea* in Cultivation," "Fern Study in Great Britain," and "Notes for the Beginner." The Bryologist is a department of the Bulletin devoted to Mosses.—*Bulletin de l'Association pour la Protection des Plantes*, March, 1898. With no

space to mention, all the matters herein dealt with, and relevant to the title of the pamphlet, attention may be drawn to the article "Les Beaux Arbres de la Suisse," the illustrations to which are very attractive.

HOME CORRESPONDENCE.

SUBSCRIPTIONS, AND THE WHEREWITHAL TO PAY THEM.—In these columns there often appear reports and other communications referring to the Gardeners' Royal Benevolent Institution and Gardeners' Orphan Fund, and to the lack of support from the gardeners. In your issue of April 9, there appears the following:—"The committee trust that every well-wisher of the first-named Institution will note that the Victorian Era Fund is still open, and donations will be thankfully received." If every well-wisher were able to contribute I have little doubt that the amount required would soon be forthcoming; but unfortunately such is not the case, for there are many who, like myself, have begun at the bottom of the ladder, and steadily worked upwards till we have reached the top, only to find that the position and title of head gardener is too often lacking in the means to properly support it. It is my present lot to be in the apparently desirable position of head gardener under a Yorkshire City Corporation; and having, when my rent is paid, the princely income, for seven days' work, of 21s. 3d. with which to purchase firing, vegetables, &c., and keep a wife and child. I saw it suggested a few weeks back that circulars should be sent round to gardeners requesting subscriptions, but I trust they will pass me by, for I can already feel my lowly position acutely enough when seeing the familiar names published now and again in your columns with a good subscription attached to them. My good wishes for such a noble institution as the Gardeners' Royal Benevolent are as sincere as those of any subscriber can be; but until my lot brightens, I trust some wealthy employer will dip a little deeper into his pocket to make up what is lacking on my side. C. C.

TURNIP-FLEA (HALTICA NEMORUM).—This little shining black beetle is found in myriads in dry weather eating holes in the early leaves of Turnips, soon devastating whole fields and beds in the garden if remedies be not taken against it. In gardens a crop of Turnips may be saved by frequently dusting the young plants early in the morning when the seed leaves are damp with dew with a mixture of soot and lime, or wood-ashes, but it is of very little use if not well followed up; of course, a rapid growth is very essential, therefore every encouragement should be given the young seedlings. There is an advantage in filling in the drills when the seed has been sown with rich soil, Moule's closet manure or other, first affording water in the drills, as by so doing the plants make rapid growth. If the weather proves dry after the seed has germinated, afford water frequently, and dust them with soot and lime before the leaves get dry. H. Markham, Margate. [Miss Eleanor A. Ormerod, in her *Manual on Injurious Insects*—chapter on *Haltica nemorum*, recommends that all plants that the beetle frequents, viz., Shepherd's Purse, Charlock, and Jack-by-the-Hedge, should be destroyed, the beetle often being supported by these plants in the spring till the Turnips appear; also all lumps of manure from the stable and cowshed should be buried or covered with soil, as these form hiding and breeding places for the insects. Ed.]

WINDOW-PLANT CULTIVATION.—A recent post brought me an enquiry from a New York publishing house as to the existence in London of any society for the promotion of the culture of plants in windows. It was not without feelings of regret I had to reply that I have no knowledge of the existence of a society taking up this special line of work. A few years ago an annual exhibition of plants grown in windows in Westminster was held in Dean's Yard, but I am not sure if that is continued. The Rev. H. Webb-Peploe used to have shows in Chelsea in connection with the Mission Rooms attached to his church in Onslow Square, and if any of these are still held they are not heard of. There were formerly exhibitions in Spitalfields, Whitechapel, and other places in the east, but I fear much the largest part of them have ceased to exist. The once famous City Flower Shows, so warmly promoted by the late Rev. William Rogers, and which were always highly successful, were abandoned some years before his death. The People's Palace Horticultural

Society provides classes in the schedules of prizes of all its exhibitions for plants grown in windows, and there is an annual inspection of window-boxes in the more congested parts of the East End, and the judges award prizes. The Mansfield House Settlement at Canning Town, holds a flower-show once a year, at which plants grown in windows are largely exhibited, and attempts are made to interest the young girls and lads employed in the factories about there in the culture of plants. R. D. [There is, or was, a window-gardening society in Mayfair. Ed.]

CATTLEYAS AND OTHER ORCHIDS.—I for one desire to record my thanks and appreciation to Mr. G. Lee for his excellent lecture on the "Culture of Cattleyas," which appeared in two recent issues of the *Gardeners' Chronicle*, for, according to my fourteen years' experience amongst Orchids, it is more to the point than anything of the sort I have ever read. Those Orchids of which I now have the charge are cultivated in a plant-stove of three-quarters span, running east and west (it would be preferable if it ran north and south). When *Dendrobiums* and *Cypripediums* are placed with a general furnishing stock of hothouse plants, one may understand how easy it is for the Orchids to deteriorate more or less after a few years. It is, therefore, most gratifying to find Mr. G. Lee's opinion on the point correspond with my own, and especially that which he says about the application of the scrubbing-brush, soft-soap, and water to imported plants; also to keeping the materials separate when potting. A. J. Nightingale.

SPARROWS AND FLOWERS.—Some observations that I have recently made in my garden, may perhaps throw some light upon the reason for the annoying depredations of sparrows. The flowers attacked are Primroses, Polyanthus, Hepaticas angulosa and triloba, Carnations and Crocuses. The Primrose and Polyanthus are bitten off just at the junction of pedicel and flower; only the petals of Hepatica angulosa and triloba are plucked off before the flowers are properly expanded. The Carnations are regularly bitten off at the tips of the leaves. At first I thought that the Carnation-leaves were bitten off by a shrew-mouse (of which one existed in the garden and ate the Freesia bulbs, and attacked some Lobelia fulgens roots in a cold-frame), but on examining the leaves I found they were not neatly nibbled off, but pulled off, leaving a bruised part; and on watching I caught the sparrows tugging at the tips of the leaves. It occurred to me that the tips of the leaves might be sweet, and on tasting them I found that they appeared to be slightly so. The fact that frost often sweetens vegetable structures containing starch, suggested that this might be a possible explanation, coupled with the fact that it is invariably on the approach of a colder atmosphere that the birds attack the flowers. As soon as the plants flower freely, they are no longer touched. Whether this is because the flowers have then utilised the sugar present, or whether because in attempting to pick one flower the next touches them, and perhaps startles them, as it might in the Polyanthus, I do not know; but think it probable, the former is the correct explanation. I notice that the shady side of the garden, where the Primroses and Polyanthus do not get much light or warmth, and the plants are not vigorous, is the side almost exclusively attacked. The yellow Crocuses are so invariably attacked in cold weather that I grow only the white and deep blue, which they do not touch. When in full flower, and in a sunny situation, I have noticed even the yellow Crocuses are not much injured, if at all. Black thread over the flowers, crossing diagonally, is the only remedy I have found of avail in protecting the blossoms. E. M. H.

COMBATING THE FOREIGNER.—It is evident that our home caterers of flowers, fruit, and vegetables, for market purposes, are neither frightened by the bogey of foreign competition, or by the recent decision of the High Court of Appeal, in relation to the rating of glasshouses, for the erection of these goes on apace in all directions. Would that it were possible to obtain annually reliable statistics as to the area of glasshouses, for market purposes, erected in the kingdom each year. Passing down the Windsor branch of the South Western Railway the other day, my attention was attracted to two new erections in my old parish of Feltham, Middlesex; the first a lofty church-tower and spire, which is costing several thousands of pounds, and will be absolutely non-reproductive; the other, a little farther down, is a huge mass of glasshouses, costing far less than the other erection, and which on recently occupied land is being built by an enterprising market grower, and

a member of an old Isleworth family, Mr. A. W. Smith. This huge group of glass when complete will consist of twenty houses, each 30 feet wide, and 600 feet long; that was the measurement given to me. Thus we see here in one block—only assuming the length of each house is 600 feet—over 2 miles of span-house 30 feet wide. This is literally glassing over the land, so as to give to it something of that summer-like character which naturally characterise the southern portions of the European continent and islands. What labour will this area of glass provide? What will it furnish in the way of food for the people? How much will it add to the health and happiness of the community? At Isleworth I learn Mr. Smith's brother has lately erected an equally large area of glass, and both will be shortly engaged in doing their best to produce early products, such as the foreigner has the chief monopoly in producing just now. This is the way to combat foreign competition, and it also serves to show that the men who have long experience in the market trade realise that there is money in it yet, for they do not sink their thousands of pounds in ventures of this description without being well assured that it will repay them. Talking with that well-known gardener, Mr. Denning of Hampton, the other day, he told me that all about his district glasshouses for market produce had during the past few years extended enormously. Hampton seems to be *par excellence* the market-growers' quarter of the metropolitan area. There were then some eighty or more of these market establishments in that district, and others were cropping up at the rate of almost one each week. This vast glass expansion must open a wide field for the energies of the Nurserymen and Market Gardeners' Hailstorm Insurance Society. One wonders how many of the persons now engaged in this great industry ever think of the efforts of those who many years ago laboured so hard to remove the tax on glass. Do they ever in their festive gatherings drink a toast solemnly to the memory of the dead and living reformers, without whose aid this vast expansion of glasshouse industry never could have been? However, it is satisfactory to note how practically our own people are striving to overcome in the production of food elements foreign domination. It is so much wiser and nobler than is sitting down to whine. A. D.

LAW NOTES.

FAILURE OF A PENZANCE FLORIST.

THE creditors of Thomas Fox, nurseryman, Buryas Bridge, and 65, Chapel Street, Penzance, first met at Truro, 12th inst. The meeting was then fixed for the 21st inst. According to the debtor's statement, £1547 is due to 55 unsecured creditors, and assets amount to £800, including stock-in-trade, £250; trade fixtures, &c., £400; growing crops, £50; furniture, £50; other property, £45; and book debts estimated to produce £5. The usual deductions leave a deficiency of £780. Debtor attributes his failure to want of capital and inexperience of nursery business, loss of the whole stock for one year by arsenical poisoning, and the complete failure of last season's fruit and early Tomatoes. Debtor states that he commenced business as a nurseryman and florist in 1894 without capital, having been previously employed as an insurance agent. Debtor was, in the opinion of the Official Receiver, greatly to blame for embarking in a business in which he had no experience. Having regard to the time the debtor had been in business, and to the very large deficiency, he considered his affairs would require strict investigation. *The Western Morning News*.

FAILURE OF A POTATO DEALER.

The first meeting of the creditors of Oswald Ignatius Smith, potato merchant, Selby, was summoned for Tuesday, 12th inst., at the York Official Receiver's office. No creditors were then present. The summary of affairs showed gross liabilities, £460 6s. 5d.; deficiency, £457 16s. 5d. The debtor attributes his insolvency to sickness of himself, wife, and family. *The Yorkshire Daily Post*.

DISPUTE IN THE SEED TRADE.—A TREE CABBAGE.

In the Westminster County Court, on Monday, his Honour, Judge Lumley Smith, Q.C., tried the case of *Howcroft v. Laycock*, in which the plaintiffs,

SOCIETIES.

ROYAL HORTICULTURAL.

APRIL 26.—The usual fortnightly meeting of the Committees of the Royal Horticultural Society was held on Tuesday last in the Drill Hall, James Street, Westminster. There was a very large display of exhibits, and throughout the day the number of visitors was unusually great, the hall at times being uncomfortably thronged. Considerable space and interest was absorbed by the show of the National Auricula and Primula Society, held in conjunction with this meeting. Upon the whole, the Auriculas were not of very fine quality, being rather rough, owing to the weather having been very far from suitable to these plants. A large share of the display was again contributed by the collections of Narcissus, which were even more numerous than on the last occasion. Orchids were shown in quantity; but one of the most remarkable and lovely characteristics of the exhibition were the groups of cut Roses. These were magnificent, and compelled admiration from every point of view. There were several fine collections of hardy plants in flower, beside the usual miscellaneous exhibits of novelties. Following so soon upon the Ghent show, where generally the ornamental foliage plants were so superior to flowering plants, the contrast was very noticeable. In the small Drill Hall there was congregated a much greater profusion of flowers, in proportion to the whole of the exhibits, than was the case in the large and excellent exhibition our Belgian friends were justly proud of. Before the Fruit Committee were two most commendable exhibits—the one a collection of fruits and vegetables, and the other a collection of vegetables alone, both from private establishments.

Floral Committee.

Present: W. Marshall, Esq., chairman, and Messrs. John Fraser, Owen Thomas, Chas. T. Drury, H. B. May, Geo. Nicholson, R. Dean, Geo. Stevens, W. Howe, J. F. McLeod, Thos. Peed, John Jennings, R. B. Lowe, W. Baines, Jas. Hudson, Chas. Jeffries, W. Bain, J. D. Pawle, Chas. E. Shea, J. W. Barr, T. W. Sanders, E. T. Cook, Ed. Beckett, H. J. Jones, D. B. Crane, Geo. Paul, H. Selge Leonard, Geo. Gordon and Harry Turner.

An award of Merit was recommended to a large-flowered variety of *Primula vulgaris*, named Evelyn Arkwright, shown by Mr. J. H. ARKWRIGHT, Hampton Court, Leominster. The original stock of the variety, it is said, was found wild in Dinmore Wood, Herefordshire, in 1887, and comes true from seed.

A fine collection of sprays of varieties of Himalayan *Rhododendrons* was shown by Sir JOHN T. D. LEWELYN, Bart. Penllergare, Swansea. They were a remarkable lot of blooms, and all had been cut from plants growing in the woods and shrubberies.

Azalea mollis × *sinensis* hybrids, from Messrs. R. & G. CUTHBERT, were very beautiful. The best varieties were Anthony Koster, Alma Tadema, J. J. De Vink, pale lemon-coloured, with decided spotting on upper petal (Award of Merit); C. Moorschalk, rather small, but densely-flowered, and of rich yellow; Sebastopol, pale salmon-rose; and General Dettler, very large flower, of distinct orange tint, with very pronounced spotting (Silver Banksian Medal).

Mr. F. Cornish, gr. to the Dowager Lady Bowman, Joldwynds, Dorking, exhibited a mass of flowers of the parasite *Lathraea clandestina* (*Bot. Mag.*, t. 7106).

Trillium grandiflorum album was exhibited as a magnificent specimen, in a 12-inch pot, from Mr. Empson, gr. to Mrs. WINGFIELD, Amptill House, Amptill. The plant had presumably been cultivated indoors, and was nearly 3 feet across, with fresh-looking large foliage, and studded closely with large white flowers. A Cultural Commendation was awarded.

Messrs. JOHN PEED & SONS, Roupell Park Nurseries, Norwood Road, London, S.E., made a large exhibit of *Cordylines* (*Dracaenas*), which were staged on the floor. In addition to the coloured-leaved section, which was very well represented, we remarked *D. alba marginata*, Excellent, Snowball, Coullingii, terminalis alba, albo-marginata, Constant, Lemoni, Goldieana, and Sanderiana; all green-leaved varieties with more or less variegation.

Messrs. R. WALLACE & CO., Kilnfield Gardens, Colchester, showed a nice lot of *Erythronium* flowers, including a distinct pale-yellow flowered variety of *E. revolutum* known as Watsoni. *E. giganteum*, *E. Hartwegii*, and *E. revolutum* were all well shown. Of *Fritillaria* there were fine blooms of *F. meleagris* alba, a small blossom of *F. pudica*, and two plants in bloom of *Lilium roseum* (*Fritillaria macrophylla*), an erect-flowering lilac-coloured species, resembling an *Anthericum*. The showy *Tulipa Gregii* was also noted in the group.

From Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, came a group of *Gymnogrammas*, among which were remarked *G. grandiceps* superba, *G. multiceps*, *G. Alstoni*, *G. Parsoni*, *G. elegantissima*, and several silver-coloured varieties, as *G. Mayii*, *G. argentea cristata*, and *G. Peruviana argyrophylla*. An Award of Merit was recommended to *Pteris cretica* Summersi, a very pretty variety of the crested *Pteris* (Silver Flora Medal).

A fine new hybrid *Polyantha* Rose med Psyche was

shown by Messrs. PAUL & SON, Old Nurseries, Cheshunt, who exhibited three plants about 4 feet high of the variety. The flowers are pink, becoming paler with age, about 2½ inches across, very double, and produced in sprays. An Award of Merit was recommended to this variety, and also to the Dawson Rose, another of the *Polyantha* section, flowers deep pink, single, foliage small. Messrs. Paul & Son also showed variegated plants of *Rosa Wichuriana*, and a new rose-coloured H.P. Rose named J. B. M. Camm.

Mr. JAS. WALTER, Thame Nurseries, Oxon, showed as many as twelve dozen blooms of *Maréchal Niel* Roses of capital quality.

Mr. W. RUMSEY, Joyning's Nurseries, Waltham Cross, Herts, made a large display of cut Roses, there being eight boxes requisitioned to exhibit these; and there were upwards of a dozen pretty bunches in bottles. Though the popular varieties *Niphetos* and *Maréchal Niel* were shown in greatest quantity, the varieties represented were very numerous, Baroness Rothschild, Mrs. Rumsey, The Queen, Duchess of Albany, and Marchioness of Londonderry being among those best presented (Silver Banksian Medal).

The group of cut Roses from Mr. GEO. MOUNT, Canterbury, was lovely. It would be next to impossible to flatter the two dozen blooms of *Catherine Mermet* by any description. In colour they were perfect, and most of them in form also. Hybrid Perpetuals, too, were beyond praise, and those shown with long stems and abundant healthy foliage were effective to the last degree (Silver-gilt Banksian Medal).

The most distinct exhibit of Roses, however, was the very fine collection of blooms of the old variety, *Fortune's Yellow*, shown from Lord WANTAGE's garden at Lockinge (gr., Mr. Fyfe). The exceeding freeness with which the plants bloom at Wantage was not only indicated by the numerous large, well-coloured blooms shown, but sprays of growth several feet long were also exhibited, and these bore numerous flowers of excellent quality. In the bud state, this old Rose is most enchanting, including shades of Apricot and rose-pink. The stems are generally very slender, and have to be wired (Bronze Banksian Medal).

A group of *Anthurium*s, and many cut spathes of additional varieties, from Sir TREVOR LAWRENCE, Bt., Burford, Dorking (gr., Mr. Bain), were very interesting and showy. A *Scherzerianum latifolia*, with eleven spathes, was a capital form of this intense-coloured variety. Another variety named *Triumphans*, with spathes nearly 8 inches long, and beautiful pink in colour, was one of the gems in the group. *Rothschildianum* maximum, with mottled scarlet and white spathes, and another with white spathes; also *elegans*, a much mottled or spotted spathe, with *Andreanum* form, were all good. Cut spathes of varieties of *A. Andreanum* were magnificent, of mammoth size, and the most brilliant colours (Silver Flora Medal).

A group of excellent varieties of *Anthurium Scherzerianum* was also shown from L'Horticulture Internationale, Parc Leopold, Brussels, and a Silver Banksian Medal was awarded thereto.

Gloxinias were shown in a group, with interspersed Ferns, by Messrs. JNO. LAING & SONS, Forest Hill Nurseries, London, S.E., and some of the best varieties so displayed were John Laing, bearing crimson flowers of good form; Mrs. Laing, purple throat, with white margins; Lady Tweedmouth, white, with rose-coloured zones; and Lady Edridge, intense purple (Silver Flora Medal).

A fine group of hardy flowering plants was shown by Messrs. PAUL & SON, Cheshunt. There were large clumps of *Doronicum plantagineum excelsum*, *Geum minimum*, *Adonis vernalis*, *Pulmonaria saccharata*, *Trillium grandiflorum*, the double-flowered *Caltha monstrosa*, *Violas*, several fine varieties of *Aubrietia*, viz., W. Marshall, Fröbelli, &c. Rarer plants included *Gerbera Jamesoni*, one of the choicest and most brightly-coloured of hardy plants; *Andromeda tetragona*, and *Bryanthus empetrifolius*. A single-flowered H.P. Rose named *Royal Scarlet*, was exceedingly vivid.

In addition to the fine collection of *Narcissi* elsewhere noticed, Messrs. BARR & SONS, King Street, Covent Garden, staged a few hardy plants in flower, including several species of *Primula*, and a few hardy *Orchis*.

An Award of Merit was recommended to *Richardia Rhodessa*, shown by Mr. J. Jennings, gr. to LEOPOLD DE ROTHSCHILD, Ascott Gardens, Leighton Buzzard. This is another yellow-flowered *Calla*, with spotted foliage, and in all respects appears as vigorous and large-growing as the ordinary white-flowered *Calla*. The flowers are of a rich shade of yellow.

Messrs. JAS. VEITCH & SONS, Limited, King's Road, Chelsea, exhibited plants in flower of *Chionanthus virginicus*, *Deutzia hybrida* Lemoinci, and *Rhododendron indicum* var. *Kämpferi*, and a pretty bright rosy-red-flowered *Azalea* with moderate-sized blooms. Messrs. Veitch showed, and were recommended an Award of Merit for *Deutzia parviflora*, a very fine-flowering *Deutzia*, and a Botanical Certificate for *Azaleodendron* Edouard André, another hybrid from *A. mollis* and *R. ponticum*, several of which have been described in these columns. A very beautiful white-flowered *Celmisia coriacea*, and a pretty, silver-spotted, ornamental-leaved *Begonia* named *Eudora*, were included in their exhibit.

Messrs. OSMAN & CO., Horticultural Sundriesmen, 132, Commercial Street, London, had a novel exhibit of needle-work from the West Indies. Natural Ferns, and other dried plants were woven up into D'Oyleys, lamp-shades, table mats, and such like articles. The work was exceedingly fine, and the effect good. It was stated that the proceeds from the sale of these tasteful novelties will be devoted to charitable objects (Silver Banksian Medal).

Messrs. Howcroft, a firm of seed merchants of Hart Street, Covent Garden, sued defendant, a market gardener of Midhurst, Hants, to recover the sum of £21 in respect of seeds supplied to his order.

The plaintiff's claim was admitted, but the defendant set up a counter-claim, in which he sought to recover £18 as damages for loss he had sustained owing to the alleged misrepresentation of the seeds supplied to him.

Mr. George Thomas Laycock was called, and said he was the defendant in the action, and had been in the habit of purchasing seeds from plaintiff for some time past. About a year ago he purchased, among other goods, a 2 lb. packet of *Couve Tronchuda*, which was a species of Cabbage sometimes used in place of *Seakale*, and was a plant of a high-class character. In due course seed was planted, but after going to considerable trouble and expense in planting and growing the goods, he found that instead of producing a plant about 18 inches high, with a fine white heart, it ran up to an abnormal length of several feet, and produced nothing but a huge thick stump and a mass of coarse leaves which were totally useless for any purpose whatever. He (defendant) had tried to sell the produce both in Covent Garden and to private shopkeepers, but no one would purchase it at any price.

In cross-examination, the defendant said that the seeds were properly sown in properly prepared ground, and everything that was possible was done to make them a success.

The plaintiff's case was that the seeds were supplied under a non-guarantee clause, and that such clause was inserted in the catalogues and invoices, and also in the *Gardeners' Chronicle*.

On behalf of the plaintiff's case, Mr. Hayward was called, and said he was in charge of the warehouse. All seeds were sold under a non-guarantee clause, not only by their firm, but by all seed merchants. The plant in question was not much in demand, as it was used principally for cattle, and was not an article of domestic use.

His Honour said he should find as a fact that *Couve Tronchuda* was an edible Cabbage, fit for human consumption, and that the plant (produced), which was the outcome of the plaintiff's seeds, was only fit for cattle. In giving judgment his Honour said he thought the plaintiffs were protected by their non-guarantee clause, and therefore judgment would be in their favour, both on the claim and counter-claim, with costs, but defendant would have leave to appeal.

EVAPORATED VEGETABLES.—According to the *Melbourne Chronicle*, Mr. F. A. Pulleine, of Lobethal, South Australia, is "making a name for desiccated vegetables and fruits; and, although several others are in the habit of evaporating fruits on a large scale, and make a first class article, he is the only one who deals with vegetables during the off-season for fruits. Carrots, Parsnips, and Potatoes, are reduced to about one-eighth part of their original bulk and weight; Onions are brought down to one-twentieth part. Reduced thus in bulk and weight, vegetables can be transported to distant parts at a very moderate cost, and they will keep perfectly good for two or three years. When required for use, the articles are soaked in five or six times their weight of water for twenty-four hours, when they are ready for cooking like fresh vegetables."

Obituary.

MR. E. MORSE.—We regret to announce the death of Mr. E. Morse, of the Epsom Nurseries, in his eightieth year. Many of our readers will remember this kindly and enterprising nurseryman, who filled many important posts, and established a large nursery business many years ago at Epsom. This will be conducted in the future by his two sons. The funeral, which took place on Tuesday, 19th inst., was attended by a host of friends and acquaintances of the deceased, some representing the local boards with which he had been for so many years connected.

Narcissus Committee.

Present: J. T. Bennett-Poë, Esq., in the Chair; Miss Willmott, Messrs. C. R. Scrase-Dickens, Jas. Walker, A. Kingsmill, F. W. Burbidge, W. Goldring, Revs. S. E. Bourne and G. H. Engleheart.

The long drought, with frost, has detracted from the size and substance of the Narcissi this season, and it may be supposed that many of the varieties shown in the trade collections had been received from Holland. This indeed was apparent from the presence of such early kinds as *N. maximus*, long since over in England. The general quality of the flowers was, however, surprisingly good.

Of the professional exhibits the palm, in point of quality and arrangement, must undoubtedly be given to that of Messrs. PEARSON, Chilwell, Notts. It is needless to particularise, for most of the best kinds in cultivation were represented by beautifully fresh flowers, arranged without crowding, in light bunches with foliage. Indeed, this group afforded a much-needed lesson in the right presentation of such flowers, and was well worth a higher Award than the Silver Flora Medal adjudged to it.

The same recognition was won by Messrs. VEITCH with a large bank of good flowers, which would, nevertheless, have been more effective had half, or a third only, of the material been employed; and the same criticism may fairly be passed upon Mr. T. S. WARE's exhibit.

Messrs. BARR & SONS had, it is superfluous to say, a fully comprehensive collection in all the subdivisions of the genus. Three very fine blooms of Weardale Perfection occupied the central place of honour (Silver Flora Medal).

The Rev. G. H. ENGLEHEART, Appleshaw, Andover, again had a stand of select seedlings. One of these, Will Scarlett by name, attracted great attention by the extraordinary depth of colour in its broad and solid cup of rich, luminous red. The raiser considers this perhaps his best achievement in high-coloured Narcissi, the plant being broad-leaved and of great vigour (First-class Certificate). He also gained Awards of Merit for White Lady, a flower in the way of Catherine Spurrell, but larger and better; for Diadem, a novel and very striking variety with sulphur divisions and a broad, flat eye of chrome, edged with a narrow ribbon of intense orange; for White-wing, a round flower with overlapping white segments, and shapely yellow crown. Mr. ENGLEHEART showed many noteworthy seedlings, including several of his new strain of *N. poeticus*.

Messrs. VEITCH obtained an Award of Merit for Ivanhoe, a quite small, neat flower of the Nelsoni class with bright-red cup.

Mr. R. BACKHOUSE, Sutton Court, Hereford, brought some seedlings of promise, mostly as single flowers, more of which should be seen for a fair judgment.

Orchid Committee.

Present: W. Thompson, Esq., in the chair; and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshaw, H. Ballantine, H. Little, A. H. Smee, F. J. Thorne, H. J. Chapman, W. H. White, W. H. Young, E. Ashworth, T. W. Bond, W. Cobb, H. Williams, J. Douglas, H. M. Pollett, E. Hill, S. Courtauld, and T. B. Haywood.

There was a grand display of Orchids, in which the *Odontoglossums* and hybrid Orchids predominated.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, staged a very effective group, for which they were awarded a Silver Flora Medal, in which the leading novelty was *Laelio-Cattleya* × *Thorntoni* (C. Gaskelliana ♀, L. Digbyana ♂), the third cross they have effected with varieties of *C. labiata* and L. Digbyana. In general appearance it resembled L. C. × Digbyana-Trianæi, illustrated in the *Gardeners' Chronicle*, Jan. 1, this year. The sepals and petals were of a pale lilac, the lip creamy-white, with yellow markings on the centre, and pale rose flush towards the enlarged and fringed front lobe (First-class Certificate).

Another fine hybrid, for which also a First-class Certificate was awarded, was *Laelio-Cattleya* × *Wellsiana* var. *Langleyensis* (C. Trianæi ♀, L. purpurata ♂), a handsome flower, with sepals and petals white, tinged with lilac. The showy lip had a yellow tinge in the tube, the front lobe being rich violet-crimson. The third fine exhibit, selected for an Award of Merit, was *Cattleya Schroderei amabilis*, a grand variety of the typical peach-blossom colour, with orange throat; and *Laelio-Cattleya* × *Ascania superba*, and L. C. × *Philo* showed these two pretty hybrids in their best form. A blaze of rich orange and red colour was given to the group by the many fine plants of the original and best form of *Lælia* × *Latona*, and striking features were good varieties of *Cattleya Mendeli*, *Masdevallia Veitchii*, with twenty flowers, the handsome *Brassia brachiata*, and *Epidendrum Wallisii* with three heads of bloom.

Messrs. LINDEN, l'Horticulture Internationale, Parc Leopold, Brussels, were awarded a Silver-gilt Flora Medal for one of the finest and most interesting groups of Orchids ever exhibited. In the group were bewildering series of varieties of *Odontoglossum Wilckeanum*, of which O. W. Lindeni was the finest and most richly coloured, though O. W. Schusterianum, O. W. Thompsoni, O. W. Ballantinei, and O. W. Stevensii, were all fine, and totally dissimilar from each other. Other fine-spotted *Odontoglossums*, to which it was difficult to assign a pedigree, were O. × *Queen of the Belgians*, a cream-white, spotted hybrid of O. Hunne-wellianum, which was also represented in variety; O. × *Princesse des Canaries*, a bright yellow flower, with fringed white lip, with some of the features of an O. luteo-purpureum, but with the thin texture and angular outline of *Miltonia virginalis*; O. × *Royal Tiger*, a very strange

flower; and among forms of recognised species and varieties, O. *Pescatorei* Roi Leopold, a fine white, with a profusion of violet spots; O. *crispum* Comte de Flandres, with one large blotch on each sepal; O. *Ruckerianum deliciosum*, O. *triumphans aureolum*, *Miltonia vexillaria*, *Memoria Lindeni*, a grand flower of a rich rose colour; *Cypripedium* × *Lebaudyanum superbum*, a charming hybrid; C. *Rothschildianum platytenium*, C. *Argus Lindeni*, *Cattleya Mendeli* "The Pearl," a lovely bluish-white, *Miltonia vexillaria candidula*, &c.

Sir TREVOR LAWRENCE, Bart., Burford, Dorking (gr., Mr. W. H. White), showed *Mcrmodes ananthum*, a fine variety of the M. *Buccinator* form, but with flowers wholly of rich claret-purple. The specimen bore four strong spikes of many flowers (Botanical Certificate).

The Rt. Hon. JOSEPH CHAMBERLAIN, Highbury, Moor Green, Birmingham (gr., Mr. Smith), sent a pretty group, in which the principal feature consisted of several plants of the pretty *Laelio-Cattleya* × *Highburyensis* (C. *Lawrenceana* × L. *cinnabarina*), of a decidedly novel hue, the sepals were of a salmon colour slightly tinged with rose, the petals veined and tinged with rose-purple, and the lip of a rich claret-crimson. Another of the Highbury hybrids shown in fine condition was *Masdevallia* × *Chamberlaini* (Harryana × *buttleworthii*), with handsome flowers of a light purple colour, bearing red lines in the centre, and reddish-yellow tails.

ELIJAH ASHWORTH, Esq., Harefield Hall, Wilmslow, Cheshire (gr., Mr. Holbrook), showed *Cattleya Mendeli* Beatrice Ashworth, a charming nearly white form, with a delicate bluish hue on the petals (Award of Merit); and *Cattleya Schroderei*, Harefield Hall var., a singular departure from the usual form of the species, the labellum being richly coloured with ruby-crimson, as in some forms of C. *Mossiae* (Award of Merit).

Baron Sir H. SCHRODER, The Dell, Englefield Green (gr., Mr. Ballantine), showed *Odontoglossum triumphans superbum*, a very large and richly-coloured form.

His Grace the Duke of WESTMINSTER, Eaton Hall, Chester (gr., Mr. Barnes), showed *Odontoglossum Pescatorei* Duchess of Westminster, a fine flower of perfect form, clear white, profusely blotched with purple (Award of Merit).

Messrs. HUGH LOW & Co., Clapton, staged an effective group, in which were several very fine *Cattleya Mendeli*, the best being C. M. Mrs. John Bradshaw, a fine bold flower, with crimson front to the lip, contrasting finely with the white and chrome-yellow of the side lobes. Among their *Odontoglossums* were O. *Pescatorei* Enfieldense, a well-formed flower, with small purple spots on the petals; some fine O. *crispum*, and O. *Andersonianum*, one plant of the latter bearing three large branched spikes; O. *Edwardi*, O. *cirrhosum*, several pretty forms of *Oncidium*, *spilopterum*, &c. (Silver Banksian Medal).

Messrs. B. S. WILLIAMS & SON, Upper Holloway, were awarded a Silver Banksian Medal for a pretty group, in which were good forms of *Cattleya Mendeli*, one of them being the light coloured C. M. *Morganiae*, the pretty little *Trichocentrum tigrinum*, *Trichopilia crispata*, and T. *lepidula*, *Vanda suavis*, and excellent forms of *Odontoglossum crispum*, O. *Andersonianum*, and others.

J. BRADSHAW, Esq., The Grange, Southgate (gr., Mr. Whiffen), showed a group composed of fine varieties of *Odontoglossum crispum*, among which was a pretty spotted form of the O. c. *Horsmanii* class, a finely-coloured *Cattleya Lawrenceana*, C. *intermedia alba*, *Brassia brachiata*, *Dendrobium Jamesianum*, &c.

H. GREENWOOD, Esq., Highfield, Haslingden, showed *Odontoglossum Humeanum*, Greenwood's variety, with cream-coloured lip, yellow sepals and petals marked with red-brown, and purple column; *Odontoglossum Hunne-wellianum maximum*, a very beautiful variety (Award of Merit), and a purple-tinted form of O. *aspersum*.

J. COLMAN, Esq., Gatton Park (gr., Mr. King), showed a grand plant of *Cattleya Lawrenceana*, furnished with about twenty flowers (Cultural Commendation).

WALTER COBE, Esq., Dulcote, Tunbridge Wells (gr., Mr. Howes), showed a fine plant of *Cypripedium* × *Gertrude Hollington* (Cultural Commendation), *Odontoglossum polyanthum*, Dulcote variety, and a fine specimen of *Dendrobium albo-sanguineum*.

DE B. CRAWSHAW, Esq., Rosefield, Sevenoaks (gr., Mr. S. Cooke), again showed the noble *Odontoglossum triumphans* var. *Lionel Crawshaw*, illustrated in the *Gardeners' Chronicle*, April 20, 1895, p. 489. Fine as it then was, it has much improved, the segments being broader, and the whole flower rounder and larger. The characteristic yellow margin and other fine features are still the same (Cultural Commendation).

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Aldous), also showed a fine O. *triumphans*.

C. L. N. INGRAM, Esq., Elstead House, Godalming (gr., Mr. T. W. Bond), sent *Cattleya Sedeni* (Lawrenceana × *Percivalianum*), like a large and bright C. *Lawrenceana*, but with more ample labellum (Award of Merit).

J. SPARKS, Esq., Heathside, Ewhurst, sent *Cymbidium canaliculatum*, received from Queensland, and bearing a dense spike of small dark purple flowers (Award of Merit).

F. W. MOORE, Esq., Royal Botanic Gardens, Glasnevin, Dublin, sent *Neobenthamia gracilis*, with a pretty head of white flowers.

Fruit Committee.

Present: Philip Crowley, Esq., chairman; and Messrs. Geo. Bunyard, P. C. M. Veitch, Jos. Cheal, G. W. Cummins, A. F. Barron, A. H. Pearson, J. Wright, Alex. Dean, W. Pope, Geo. Wythes, J. Smith, W. J. Empson, J. Willard, Geo. Norman, and H. Divers.

The best Apple in the competitive class for flavour was Allen's Everlasting, shown by Colonel BAYMEE, Hillington House, Dorchester. The fruits were obtained from a bush-tree on the Paradise stock, and were excellent for this part of the season. The 2nd prize was awarded to Herefordshire Pearmain, shown by C. P. SEROCOLD, Esq., Taplow Hill, Maidenhead.

An Award of Merit was unanimously recommended to Melon Lord E. Cavendish, a fine fruit, with greenish white flesh, very fine in flavour, especially for April, shown by Mr. O. THOMAS, Royal Gardens, Windsor.

A magnificent collection of fruit and vegetables was shown by Mrs. WINGFIELD, Amptill House, Amptill (gr., Mr. W. J. Empson). Of fruit we remarked a bunch of Bananas, about a dozen well-fruited plants of Royal Sovereign Strawberry, and a dish of same, and of the variety Sir Joseph Paxton, several sorts of Apples, including a seedling from Beauty of Kent, ripe Tomatos, also Rhubarb, Cucumbers, and various vegetables, of which the most noticeable were the uncommonly fine Leeks of the varieties Lyon and Holborn Model (Silver-gilt Banksian Medal).

A no less remarkable collection of vegetables was that from Lord PERCY, Syon House Gardens, Brentford (gr., Mr. Geo. Wythes). The group included about thirty-three dishes, and many of these were obtained by forcing. New Potatos, Peas, Tomatos, Cucumbers, Lettuces, French Beans, Asparagus, Carrots, Mushrooms, Seakale, very fine; Leeks, and a fine lot of green vegetables were all excellent (Silver-gilt Banksian Medal).

An Award of Merit was recommended to a first-class strain of Sprouting Kale shown by Mr. J. READ, gr., Brethby Park, Burton-on-Trent.

Messrs. JAS. VEITCH & SONS showed Market Favourite Broccoli, a variety with moderate-sized, compact, white heads of very good appearance.

A Cultural Commendation was deservedly awarded to Mr. H. T. Martin, gr. to Lord LEIGH, Stoneleigh Abbey, Kenilworth, for very finely grown Seakale, some of the heads being nearly 1 lb. in weight.

Lecture.

In the afternoon a lecture was delivered by Mr. F. W. BURBIDGE, M.A., Curator of the Botanical Gardens at Trinity College, Dublin, upon "Sweet-scented leaves versus Fragrant Flowers." Collections of sweet-scented plants were kindly lent by the Director of the Royal Gardens, Kew, Messrs. Jas. Veitch & Sons, and Mr. Jas. Hudson, and these served to illustrate the discourse. The hall was greatly thronged at the time Mr. Burbidge was speaking, and the consequent noise prevented his audience hearing the lecture with any degree of comfort.

NATIONAL AURICULA AND PRIMULA Southern Section.

APRIL 26.—The annual exhibition of this Society was held on Tuesday last at the Drill Hall, James Street, Westminster, in conjunction with the meeting of the Royal Horticultural Society.

That the Auriculas generally were rough, and the show varieties especially so, was readily acknowledged. There was no lack of vigour in growth, but the cold easterly winds, and especially the low temperature at nights, caused the pips to expand in a halting way; extremes of temperature always produce roughness, hence there was a great lack of finish. That there is no falling off of interest in the cultivation of what has been described as a "lovely and fascinating flower" was seen in the number of entries; there were eight entries in the class for twelve show Auriculas, but four only found themselves able to compete. Flowers that it was hoped would have been in bloom failed to be sufficiently advanced, and it was the same in the class for six varieties. The 1st prize collection of twelve came from Mr. J. DOUGLAS, Great Bookham, but the award occasioned some surprise, as it was thought by certain experts that the balance of quality lay with Mr. C. PHILLIPS' collection, which was placed 2nd. Mr. DOUGLAS had of green edges, Mrs. Henwood, a neat variety, but somewhat coarse as shown; Dr. Hardy, raised by Mr. B. SIMONITE, a much more refined variety than the preceding, and Greenfinch. Grey edges: Olympia, a large and showy variety, but as shown, certainly lacking refinement; George Lightbody, and Marmion. White edges: Mrs. Dodwell and Acme; and self: Negro, Mrs. Potts, and Black Bess, these were the leading varieties.

Mr. C. PHILLIPS, Bracknell, had of green edge, Mrs. Henwood; grey edges: George Rudd, Marmion, and Dr. Kidd; white edges: Rachel, John Simonite, Mrs. Dodwell, and Miss Woodhead; self: Mrs. Barnett and Mrs. Phillips, two fine varieties raised by the exhibitor, and certain to come to the fore for their superb quality.

Mr. SMITH had green edge James Hannaford, in good character; it is comparatively new, and this was the only example of it which came under notice. He also had grey edge Dinham, one of the late Mr. R. K. Penson's raising, the pip large, with a reddish body colour.

Mr. PHILLIPS, who has gained a position as a most successful grower for exhibition, was an easy 1st with six varieties; he had Mrs. Henwood, green edge; Richard Headly and George Rudd, grey edges; John Simonite, white edge; and Miss Barnett, self. Mr. W. SMITH was 2nd, his green edge The Rev. F. D. Horner; and his self, Mrs. Potts and Black Bess, with three others. Mr. BENNETT-POË was 3rd, showing Buttercup, a bright yellow self, a type that does not appear to be highly valued by some experts, perhaps because the contrasts are not sharp enough.

The class for four show varieties brought ten entries, and here again it was considered by some that the judgment was at fault. Mr. J. SARGENT, Cobham, was placed 1st, with Abbé Liszt, green edge, with sixteen expanded pips, a strong plant certainly, as it was selected as the premier Show Auricula in the whole exhibition; Lancashire Hero, grey edge, Mrs. Odwell, white edge, and Mrs. Potts, self, but the latter so large, rough, and out of condition, that it was scarcely recognisable. The 2nd prize went to Mr. A. S. HAMPTON, of Reading, a young grower who is likely to make his mark as a cultivator. He had a well-balanced quartette, consisting of the Rev. F. D. Horner and Lancashire Hero, green edges; George Rudd, grey, with eight good pips, and Heroine, self. There were eleven entries of two varieties. Mr. P. HENNELL, Winchmore Hill, was placed 1st, with green edge the Rev. F. D. Horner, and white edge Acme, both very good; Mr. A. SARGENT came 2nd, with green edge Abbé Liszt, and white edge John Simonite.

In the classes for single specimens, there was, as usual, a goodly number of plants. Mr. C. PHILLIPS had the best green edge in Mrs. Henwood; Messrs. SARGENT and DOUGLAS following in order with the Rev. F. D. Horner. The best grey edge was Old Lancashire Hero, from Mr. J. SARGENT. This latter exhibitor led the way with white edge, having Heather Bell; Mr. J. Gilbert, gr. to the Rev. R. L. Flood, Merrow, was 2nd, with Acme. Of selfs there was a good representation. Mr. A. FISK, Broxbourne, was 1st, with Heroine; and Mr. W. SMITH 3rd, with the same.

There was, as usual, the collections of fifty Auriculas, which are retained to add to the area of the exhibition without much increase of interest. Mr. DOUGLAS was 1st, with a collection which included of green edges, Monarch, very rough; Dr. Hardy, and Abbé Liszt; grey edges, Dinham, Ajax, Old Ringleader, very good; Silvia, George Rudd, and R. Headly; white edges, Heather Bell, Venus, and Lady Randolph Churchill, both new varieties raised by Mr. Douglas; and of selfs, Ariel and Ruby, two red-margined varieties, a class which needs strengthening; Lord of Lorne, Black Bess, and Blackbird.

The Premier Show Auricula was Mr. SARGENT'S Abbé Liszt, with sixteen pips, showing a good deal of refinement.

The ALPINE VARIETIES, always so bright and showy, made a brave display, though there were tendencies to roughness in many of the flowers. Size appears to rule, and with increased size comes the tendency to coarseness. Here Mr. C. PHILLIPS, who is now one of the foremost raisers of new varieties, was 1st with twelve, his leading gold centres, Evelyn Phillips, Vandyke, Mrs. Martin Smith, and Mrs. Gorton; white centres: Lady C. Walsh, Edith Western, Perfection, and Sister Mary, all raised by the exhibitor. As the plants were large, and as alpinas can on the exhibition-table carry all the trusses they can produce, they form striking masses of bloom. Why the show varieties should be restricted to one truss of bloom only, is probably in the interests of size and quality; Mr. J. DOUGLAS was 2nd, also with fine seedlings, mainly of his own raising. He had of gold centres—Firefly, very bright, and extra fine; Dean Hole, extra fine; Britannia, Orelia, very handsome; and Queen of the East; white centres: Toujours Gai and Mrs. H. Turner—altogether a very good selection.

With six varieties, Mr. J. W. Euston, gr. to Mrs. WHITBOURN, Great Gearies, Ilford, was 1st; he had some fine varieties, locally raised, of gold centres, these were—The Bride, bright orange-salmon, very fine, Schubert, Psyche, Urania, and Calypso; with white centre Tennyson. There were nine entries of four alpinas, Mr. J. W. EUSTON, again taking the 1st prize, having Hiawatha, a very fine variety.

The best specimen gold centre was Clara Phillips from Mr. C. PHILLIPS. Mr. PHILLIPS also had the best white centre in Perfection, a promising new variety.

The premier Alpine auricula was Mrs. MARTIN SMITH, a bright and striking gold centred variety raised and exhibited by Mr. C. PHILLIPS.

Fancy Auriculas were also shown in twelves, nondescripts—that is sportive Auriculas of various characters which cannot be classed, and yellow selfs. They appear to attract but little attention. The GUILDFORD PLANT CO. was 1st.

Fancy Polyanthuses were showy and effective, shown in collections of twelve, but there was coarseness observed among them. Mr. J. DOUGLAS was 1st.

PRIMULAS AND PRIMROSES.

Mr. DOUGLAS was the only exhibitor of twelve pots of Single Primroses, but with one or two exceptions they were coarser than we have seen before.

Double Primroses were not good. Messrs. PAUL & SONS, Old Nurseries, Cheshunt, were 1st with six large pairs of ordinary varieties; and the GUILDFORD PLANT CO. 2nd. The latter had two of the finest varieties, the Crimson and Late Yellow.

Species of Primulas made an interesting display as they always do. Mr. J. DOUGLAS was the only exhibitor of a collection of twelve, staging P. Sieboldii verticillata, mollis, japonica, and a pale variety, intermedia rosea, decora, floribunda, pubescens, very fine, and a poor pink form also, with Forbesii. Mr. J. W. EUSTON had the best six, staging verticillata, obconica, Forbesii, floribunda, intermedia, and Auricula.

Mr. J. T. BENNETT-POE had the best basket of Primroses and Polyanthus, showing fine quality.

The best collection of species and varieties of Primula or Auricula in a box or basket came from the GUILDFORD PLANT CO., who had Fancy Auriculas arranged with tuft and dwarf carpet plants. Mr. PURNELL-PURNELL came 2nd with a few species, prominent being Sieboldii, and show and alpine Auriculas. Mr. J. DOUGLAS, who appeared to have the best representation, was 3rd.

SEEDLING AURICULAS.

No new show varieties were exhibited, but prizes and Certificates of Merit were awarded to the following new varieties:—Miranda, gold centre, black ground, shading to amber tinted with red, fine shape and substance—this came from Mr. C. PHILLIPS; also to Mrs. Barefoot, much in the way of the preceding, but having a denser ground-colour, also of fine quality, from Mr. J. BAREFOOT, Croydon. Certificates of Merit were also awarded to grey-edged Olympus (DOUGLAS), of large size, weak in the tube, good paste, and slight dark body colour, and correct edge; to Mrs. Dranfield (PHILLIPS), a violet self, fine pip, smooth good tube and paste; to Alpine Firefly (J. DOUGLAS), gold centre, maroon shaded with bright crimson, fine quality, and very striking; and to Hiawatha (J. DOUGLAS), gold centre, with a dark ground, shading to deep salmon, large and smooth.

Prizes were offered for show and alpinas Auriculas by maiden growers, and an encouraging competition ensued.

CHESTERFIELD CHRYSANTHEMUM, SPRING SHOW.

APRIL 20.—The show of spring flowers in connection with the above Society was held in very favourable weather in the grounds of Wingerworth Hall, by kind permission of Col. ALLEN, and the numerous visitors much enjoyed not only the show, but also a ramble round the grounds and the kitchen gardens, which alone measure 5 acres in extent.

Although too early in the season for a vegetable garden to be very attractive, the sight of big batches of early Cabbage ready to cut, and numerous rows of early Peas, appeared to interest many of the visitors, while others were much pleased with the sight of a border of mixed Wallflowers 100 yards long and 3 feet wide. The amount of fruit blossom is promising a good crop, if late frosts keep off, while indoors Peaches, Grapes, and Figs are carrying satisfactory crops of fruit; and a long span-roofed house full of flowering plants, such as Roses, Mignonette, Spirea, Deutzia, &c., came in for a full share of admiration, and Mr. Burke deserves praise for the clean and neat aspect of the gardens. Returning so as to see some more of the 30 acres of pleasure-grounds, we noted some very fine trees and old shrubs, a Portugal Laurel which was 80 yards in circumference, a pair of fine Weeping Ash trees, a very large variegated Sycamore, and several fine old Yews.

The show itself was an improvement on previous years, and in the class for a group of plants including bulbs, Mr. Jenkinson, gr. to S. BURKITT, Esq., Stubbin Court, gained the Silver Medal, with well-bloomed plants of Azaleas and A. mollis, grand potfuls of Mignonette, Cinerarias, &c. Mr. Austin, gr. to L. BRITT, Esq., Berry Hill, Chesterfield, gained a Bronze Medal for 2nd prize.

For a well set-up collection of hardy flowers, the Silver Medal went to Mr. Bloxham, gr. to R. F. MILLS, Esq., Tapton Grove; while Mr. Nelson, gr. to A. BARNES, Esq., Ashgate Lodge, showed finely twelve bunches of flowers, stove or greenhouse. Mr. JENKINSON showed Dendrobium Wardianum in excellent condition as a specimen Orchid; while Mr. NELSON gained 1st for three Orchids. The last-named also gained premier position for Mignonette, Deutzias, Lily of the Valley, Tulips, Azalea indica, A. mollis, Cinerarias, and specimen Palm; while Mr. BLOXHAM put up twenty-four varieties of Narcissus blooms in fine condition, clean, and of good size. Mr. NELSON also staged in this class, and was awarded 2nd prize.

For six Ferns, Mr. H. Wood, gr. to A. T. BARNES, Esq., Chesterfield, was the only exhibitor, and he also showed Richardias in good condition.

Mr. NELSON put up a pretty group of flowering plants, not for competition, in which several of M. Crozy's Cannas were conspicuous, as well as three specimens of the old Spirea runcus very well bloomed; and Mr. VICKERS, market grower of Wingerworth, showed a group of plants as grown or sale.

The amateurs who distinguished themselves on this occasion in the class for a group of plants arranged for effect were Mr. S. MAY, 1st, Mr. BURR following closely, but was lacking in colour—all creditable groups to be put up in mid-April.

If the Gardeners' Orphan Fund does not benefit by this latest attempt, it will not be the fault of the gardeners in the Chesterfield district, as they have proved themselves willing once more to make a show without any prospect of prize-money, and are deserving of encouragement in the object they have in view, viz., to promote amongst the toiling masses, as well as those in more affluent circumstances, a love of plants and flowers.

DURHAM, NORTHUMBERLAND, AND NEWCASTLE BOTANICAL AND HORTICULTURAL.

APRIL 20, 21.—It was generally agreed that the show was the best that has been held under the auspices of the society for many years. The display in all sections was beautiful but unequal, and the stands were so arranged that the visitor, on entering, saw a lovely vista of bloom in which a multitude of colours was charmingly mingled. The Hyacinths, on the left, were arrayed in long rows of magnificent spikes; the table decorations were in the centre; and there were Tulips, Auriculas, Daffodils, Cinerarias, and many more plants on the right. Near the entrance there was a margin of superb Azaleas,

fairly smothered in red and white blossoms; skirting the interior on either side were miscellaneous decorative exhibits; and in front of the stage were the "groups" of plants, fringed by a collection of Deutzias, covered with snow-white blossoms.

The competition in many classes was very close. The judges in the competitions were Mr. JAMES DOUGLAS, of Bookham, Surrey; and Mr. CHAS. PAUL, Old Trafford Gardens, Manchester.

The class for a group of miscellaneous plants, arranged to produce artistic effect, was well competed for by five exhibitors, and the arrangement in the best of these was very satisfactory. The 1st prize was taken by Mr. Geo. McDougal, gr. to Mr. W. PEASE, Arcot Hall, Dudley, Northumberland; 2nd, Mr. J. McIntyre, gr. to Mrs. G. PEASE, Woodside, Darlington.

Mr. J. MCINTYRE had the best group of three plants in bloom, and also the best three Azaleas; but was beaten by Mr. T. Wheeler, gr. to Mr. C. W. MITCHELL, Jesmond Towers, for three Orchids, and for three Hippeastrums.

The best groups of Cinerarias and Deutzias were from Mr. W. Pitt, gr. to C. L. BELL, Esq., Wolsington Hall.

A group of six plants of Primula sinensis, from Mr. Geo. McDougal, gr. to Mr. W. PEASE, Arcot Hall, was very commendable.

The best Cyclamens were from Mr. T. WHEELER.

Auriculas and Polyanthuses were exhibited in most of the classes for these plants, but they were not so good in quality as in many previous years.

The show of bulbous plants in flower was an average one.

The best collection of twenty-four Hyacinths, in not fewer than twelve varieties, was shown by Mr. Geo. McDougal; and Mr. D. WYLLAM, Shankhouse, had the best group of twelve plants in nine varieties.

Cut flowers were few, but the table-decorations were good, and considerable interest was shown in them.

Among the winners of 1st prizes in this section were Mr. F. EDMONDSON, Newcastle; Messrs. PERKINS & SONS, Coventry; and Mrs. B. FENNING, Newcastle.

There were also fifteen additional classes for plants in bloom, from which nurserymen were excluded.

THE PEOPLE'S PALACE HORTICULTURAL.

APRIL 23.—The usual monthly lecture was delivered on above date by Mr. ROBERT FIFE, Orpington, Kent, who took for his subject "Plant-culture," not dealing so much with cultural details as with the central or cardinal points of culture—some of the simple scientific facts lying at the basis of the process. In the course of his address, Mr. Fife gave an interesting account of some experiments he had been, and was still carrying out, at Orpington, by way of reaching conclusions as to the best soils and constituents of manures adapted to certain plants. The details of experiments with vegetables much interested the auditory. The next lecture will be given by Mr. George Gordon, V.M.H.; subject—"The Wonders of the Fern World," illustrated by limelight views.

The annual report of this Society for 1897 has just been issued, and it shows that there has been a substantial increase in the number of members, that four successful flower-shows were held in the year, and that they were largely attended. The entries for the four shows were 1085, representing 212 classes, and cash-prizes were awarded to the amount of £75 16s. 3d., exclusive of medals, and twice a year there is an inspection of flower gardens, greenhouses, and window-boxes. Several prizes are awarded. The educational work of the Society is furthered by means of monthly lectures, and on these occasions members are invited to bring plants and flowers, to which marks are awarded, the marks carrying corresponding prizes at the end of the year. An excursion to some place of horticultural interest takes place every year. The accounts show an income of £154 18s. 7d., and there is a small balance in hand at the bank. The report expresses a desire to see a large increase in the membership.

SOCIETY OF ARTS.

SOURCES OF COMMERCIAL RUBBER.

SUMMARY of the Lecture delivered April 25, 1898, by Dr. D. MORRIS, C.M.G.—"There is a consensus of opinion that in nearly all localities in Central America the trees of Castilloa elastica are being gradually exterminated. Hence, the supply of rubber from Mexico, Guatemala, Nicaragua, and the United States of Colombia is steadily diminishing. The interesting tree yielding Ceara-rubber (Manihot Glaziovii) readily propagates itself, and its area has not apparently sensibly diminished of late years. The people are, however, being more and more attracted into the rubber districts of the Amazon valley, and the amount of Ceara-rubber exported is comparatively small.

Mangabeira-rubber, on the other hand, seems to be increasing. The tree (Hancornia speciosa) is found in the States of Pernambuco, Bahia, Rio de Janeiro, and extends westward to Matto-Grosso. The rubber is cured by means of alum, it is of a pinkish colour, and the price is generally only one half of that of fine Para. Passing on to the rubber-producing areas of the Old World, it was stated that the rapid development of African rubber was one of the most remarkable

incidents of recent years. As regards the world's commerce, Africa now occupied an important place as a source of India-rubber. The value of the imports of African rubber into the United Kingdom during 1896 amounted to over one million sterling. Of this, foreign possessions supplied rubber to the value of £206,972, and British possessions £844,840. Up to within a recent period, all the rubber produced in Africa was obtained from climbing plants belonging to the genus *Landolphia*, with sweet-scented flowers, and edible pulpy fruits. In 1894, a new rubber-tree (*Kickxia*) was found at Lagos, from which, in 1895, rubber to the value of nearly £300,000 was exported.

More recently still, another new rubber-plant (*Carpodinus*), has been discovered in Africa. This is of a semi-herbaceous character, with underground stems, which are rasped in water, and yield rubber of excellent quality.

The rubbers of Assam, Burma, Penang, and Singapore were then dealt with. Borneo rubber, although known since 1798, has only come into commerce within the last fifty years. It is yielded by climbing plants, closely related to the *Landolphas* of tropical Africa, and is generally of excellent quality.

New Guinea rubber is in part yielded by a species of *Ficus*. The natives are said to allow the sap to run over their arms and body, and when hardened they remove it and roll it up into balls the size of cricket-balls. The prospects of obtaining some of the future supplies of rubber from cultivated trees were favourable regarded. In selecting sites for plantations, preference should be given to localities in which the trees were already found. Para rubber-trees, introduced to the East at the expense of the Government of India, had done remarkably well in Ceylon, Tenasserim, and the Straits Settlements. In Ceylon, such trees were estimated to yield 120 lb. of rubber per acre after the tenth year. This would give a probable return of 20 per cent. on the capital invested.

In the Straits Settlements the trees were found to yield at an earlier age, and the estimated returns per acre were placed as high as 30 per cent. It was stated that where rubber-trees were cultivated under suitable conditions they would probably yield a larger quantity of milk than wild trees; also that the rubber, from the greater care and attention it would receive, would be more uniform in quality, and therefore obtain a higher price.

THE MARKET GARDENERS, NURSERYMEN, AND FARMERS' ASSOCIATION.

This Association, of which HERBERT B. BELL, Esq., is the Secretary, and whose offices are at 32, King Street, Covent Garden, London, W.C., request us to publish the following communication, which is signed by Mr. WILLIAM POUPART, President of the Market Gardeners', Nurserymen's and Farmers' Association.

"AGRICULTURAL RATES ACT.

SMITH AND OTHERS v. RICHMOND.

The Court of Appeal, reversing the Judgments of the Courts below, has held that "Glass Houses" are not to have the benefit of the relief given by the Agricultural Rates Act, 1896, to "Market Gardens and Nursery Grounds."

Having regard to the importance of the question to Growers, my Association has determined to carry it to the House of Lords if we can secure the support of the Trade generally.

We have many calls on our funds, and it is felt that the serious expense involved in proceedings of such widespread interest should not be wholly thrown on the subscriptions of our Members.

Growers throughout the country are invited to inform our Treasurer, Mr. GEORGE MONRO, by letter, addressed on or before the 30th inst., to the Offices of the Association, as above, what financial support they are under the circumstances prepared to afford the Association."

Mr. HOLLIS, of Worthing, contributes £7, and it is to be hoped that many will follow his example.

BRITISH ORCHIDS.—Mr. A. D. WEBSTER, of Greenwich Park, announces for immediate publication, by J. S. VIRTUE & Co. LTD., a work on "British Orchids." The book will contain an exhaustive description of each species of our native Orchids, and will be fully illustrated.

A FOREST SCHOOL FOR THE U.S.A.—The first school of forestry in the United States has been established by New York State, the legislature of that State having given the sum of 10,000 dollars for the expenses of the first year, and authorised the purchase of some 30,000 acres of forest land for the purpose of study.

NOTICES TO CORRESPONDENTS.

ADDRESS: C. H., writing from Bath, is requested to establish his *bona fides* by kindly furnishing his full name and address—not necessarily for publication.

ANDROMEDA: Enquirer. The genus is more or less narcotic, and *A. polifolia* is an acrid narcotic fatal to sheep; and *A. ovalifolia*, a Nepalese species, is poisonous to goats.

ARALIA VEITCHII: M. R. M. Generally grafted on *A. Guilfoylei*.

BOOKS: E. Challoner. A large amount of information of the kind required is obtainable from a manual entitled *Bulbs and Bulb Culture*, illustrated, by Mr. D. T. Fish, and published about 1877 by Mr. Upcott Gill, at the office of the *Bazaar*, 170, Strand, W.C. This manual appeared in several parts. *The Propagation and Improvement of Cultivated Plants*, by F. W. Burbidge, contains much original matter on bulbs. It may be met with at the second-hand shops.

BULBS: L. B. We regret that the *Narcissi* arrived in such a condition as to be unrecognisable. The *Tulip* is a form of *T. Gesneriana*, but we cannot give the varietal name; send to some trade grower.

CURRENT-BUD MITE: G. J. and W. L. It is strange that growers do not seem to read about what concerns their business. This has been described and figured repeatedly in our columns. We fear there is nothing to be done but to cut off and burn all the affected shoots. It is a very serious matter for fruit-growers. See especially *Gardeners' Chronicle*, February 19, 1898, p. 119, col. ii.

CANNON HALL MUSCAT: D. N. M. In some varieties of Grapes the flowers possess stamens that incline outwards and downwards, so that the pollen-grains although not deficient in quantity, fail in numerous instances to get deposited on the stigma, hence partial or complete sterility. This may be averted by using its own or other Grape-pollen. We do not know if the flowers of this variety are so formed, but they may be. The treatment afforded is of the right kind, as is shown by the good crops of Grapes obtained from the other Vines in the house.

DISEASED PLANTS: M. R. M. The "mining" larva of a fly, *Phytomyza nigricornis*; burn the affected leaves.

INSECTS ON LAWN: E. T. Daddy Longlegs (*Crane-fly*) grubs. Stir the surface, and turn the ducks and chickens into the garden. The female of the *Crane-fly* lays her eggs in grass and rough herbage in the autumn, and it is at that season that the most effective measures can be taken. Penning sheep on the land prevents the deposition of eggs, and gets rid of the growth of grass; so does close-mowing, followed by bush-harrowing. Much dampness in the soil favours the increase of the caterpillars, whilst draining has the contrary effect.

LIFTING BULBS: W. S. The roots of *Narcissus*, *Hyacinths*, *Scillas*, *Chionodoxa*, *Crocus* may be dug up when the foliage is in process of dying down. Tulips should be removed from the soil when the flower-stalk can be twisted round the finger without breaking, and to leave them longer is to run the risk of a renewal of growth if the season be moist. The first, third, fourth and fifth need not be dug up unless the bulbs are in the way of summer flowers, or replanting is considered necessary.

LUPINUS POLYPHYLLUS: Anxious One. The time named on the packets is a suitable one, the resulting plants being small and compact by the end of the growing season, and well able to go through the winter safely. Seed sown now would not produce flowering plants this year, but they would be long and straggly, and liable to injury from rough winds, &c.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—*G. D. L.* 1, *Rhipsalis saglionis*.—*G. H. S.* 1, *Lonicera* sp.; 2, *Dorstenia contrajerva*; 3, not recognised; 4, *Myrica Gale*; 5, *Mercurialis perennis*.—*W. C.* *Fritillaria Meleagris*, white variety.—*E. E.* *Amelanchier vulgaris*.—*E. S. R.* 1, *Cochlearia officinalis*; 2, *Cotyledon Umbilicus*; 3, *Sedum sexangulare*; 4, *Pinus excelsa*; 5, *Asplenium Trichomanes*; 6, *Polystichum angulare viviparum*.—*Mrs. H.* *Azara dentata*.—*J. Pentland.* 1, *Omphalodes verna*; 2, *Orobanchaceae*; 3, *Saxifraga crassifolia*.—*G. C.* 1, *Amelanchier vulgaris*, snowy *Mespilus*; 2, *Anthericum lineare variegata*; 3, *Forsythia viridissima*; 4, *Kerria japonica*.—*C. A. B.* 1, *Hibiscus Cooperi*; 2, *Selaginella stolonifera*; 3, *Asplenium viviparum*; 4, *Gazania splendens*; 5, *Lantana*, one of the garden forms; 6, *Cliveia (Imantophyllum) miniata*.

—*E. H. Sheffield.* 1, seems to be a yellow-tinted form of *Dendrobium Ainsworthii*. It may not prove constant; 2, 3, 4, 5, and 7, varieties of *D. nobile*; 6, a sparsely-spotted variety of *Odontoglossum Andersonianum*.—*E. H.* 1, *Doronicum plantagineum*; 2, *Saxifraga crassifolia*; 3, *Acalypha marginata*.—*L. P., Devon.* 1, *Dendrobium primulinum*; 2, *Dendrobium cucullatum* of gardens; 3, *Lycaste (Bifenaria Harrisoniae)*.—*G. A. I.* *Tulipa sylvestris*.

PEACH FOLIAGE: Gardener. The leaves sent are affected by mildew, and you would do wisely to cut off and burn the worst affected of them, afterwards syringing with some of the remedies against mildew sold by florists, or sulphide potassium at the rate of half an ounce to one gallon of water, doing this forthwith, or the mildew will extend to the fruits.

PEACH-BLOSSOMS NOT SETTING: E. P. Unless we could see the trees and knew the kind of culture adopted, we could not give a definite answer. We should imagine from the shoot sent that the very immature state of the wood is the cause of the flowers dropping without setting. The flowers that form at the green ends of ordinarily-ripened shoots drop off from the same cause.

PEACHES: B. W. The silver-leaf disease, the cause of which is not known. Cut off all the affected shoots and burn them, watering at the roots with weak solution of sulphate of iron—half an ounce to a gallon may be tried.

STRAWBERRY: T. S. We suspect your fruits are a variation from *Noble*; but it is impossible to tell from the fruits sent.

THE IPS ON PEAS: Peas. You might protect the Peas by syringing the haulm with petroleum emulsion, that is by making a strong soap ley with soft-soap 4 oz. and a wineglassful of petroleum to 1 gallon of water. Several applications may be needed. Quassia-water might also be tried, or even frequent applications of clean water or soapy water by means of the garden-engine would have a deterrent effect. If the land is light, mulch it on both sides of the rows; or if you grow Peas in a quarter by themselves, mulch the land all over.

TUBEROSE: M. R. M. Probably the flower-spikes started too rapidly for the root to support them to maturity. You omitted also to remove the offshoots, and for some reason they have become affected by "rust."

TULIP WITH A TWO-FLOWERED STALK: G. B. This is a case in which two flower-stalks have, from some unknown cause, grown together from the first, dividing, however, an inch below the flower, each branch bearing one flower. Fasciation in the stems and stalks of bulbs is not rare, but two-flowered Tulips are very uncommon, either on one or separated stalks.

VINES NOT SETTING: T. Jenkinson. Unless we knew more about your mode of treatment we cannot advise you.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED,

and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Markets and Weather, see p. xii.)

THE Gardeners' Chronicle.

SATURDAY, MAY 7, 1898.

THE CHRONICLE OF A LITTLE CORNISH GARDEN.

(Continued from p. 197.)

APRIL 1.—Since I wrote my last notes, full of optimistic references to spring's arrival, I have received my rebuff. Nature, indignant at my presumption in attempting to forecast her intentions, has sent a couple of hurricanes across my garden. The result has, of course, been a check to the march of my spring flowers, and thus my garden does not appear so very much further advanced than it did a month ago. To some extent, the flowers most in evidence then—Anemones, Primroses and Daffodils—are the ones which are most prominent now. Still, others appear almost every day, and fresh shoots and leaves inform me that but a little patience is needed in order that my garden flora may present me with an entirely new picture. Compared with last year, my early Tulips have been a failure. Something has damaged a number of the bulbs, so that the leaves and flowers appear puny and worm-riddled. The late-flowering Tulips, however, seem to have escaped, and in a week or two I expect a brilliant show from them. I am especially looking forward to a mass of *Tulipa Gesneriana*, which I planted last autumn. My early Tulips I have carpeted, some with Rock-foils, others with Iceland Poppies, and yet others with Pinks. Thus the partial failure this year does not disfigure the border, as would be the case if the Tulips stood on the bare earth; and at the same time the formality of the dazzling flowers is considerably softened.

One of the finest and most interesting flowers of April is the "Crown Imperial, Emperor of Flowers," as Chapman called it. Gerard went so far as to give it the first place in his *Garden of Delight* "for its stately beautifulnesse." Long before its flowers appear, its light green leaves materially help to decorate the early spring border, and to afford a background for the flowers of March. The clusters of curious red and yellow flowers at first look upwards, but as the flowers open they become pendent bells, and thus exclude flies, beetles, and such undesirable guests from the feast of honey secreted by the bases of the six perianth leaves. This feast is prepared for bees, and they alone are able to reach it.

The dwarf species of Fritillary are all interesting, and worth cultivating. They mostly produce graceful bells of the dullest colours, fantastically chequered. [Even the pure white form of *F. Meleagris* has a chequered pattern. ED.] *F. aurea* was the first to flower with me, and is one of the handsomest, its golden flowers being beautifully marked with numerous black dots. *F. Meleagris* (the chequered guinea-hen flower), in all its shades of colour, is worth growing in every garden. At present I have only a few plants, but next autumn I shall get a quantity, and plant in various

selected spots. Another species, especially valuable, is *F. pallidiflora*, with beautifully marked large yellow flowers. This, however, is as yet too costly to purchase in quantity, as also is *F. recurva*, a large species with reddish-orange flowers, which is unfortunately scarcely hardy.

No garden is so badly situated but it may grow the *Doronicums*, and few spring flowers are more showy. Care must be taken, however, not to introduce them too freely among small subjects, as their vigorous roots soon take possession of the ground in all directions. The species I have are *D. austriacum* and *D. plantagineum excelsum*, which are, I believe, the best. The *Doronicums* succeed in the shade as well as in full sun.

This remark does not apply to some other plants now in flower which are frequently grown in the shade. I mean the perennial *Alyssums* and *Candytufts*, which only show their brilliant white and yellow masses to perfection in the full glare of the sun. On the other hand, the *Hepaticas*, of which I have splendid clumps in bloom of double and single, red and blue, thrive best in the partial shade of deciduous trees. The other important part of their culture is to leave them alone. The present month produces what is surely the bluest flower in the world, that of the vernal *Gentian*. I have a clump in full exposure to the sun, with buried stones about the roots to retain moisture, and throughout the day the brilliant blue five-cleft discs are dazzling in their beauty. The same situation, I find, suits *Gentiana acaulis*, whose erect blue bell-shaped flowers are more frequently to be seen than the dwarf *G. verna*.

A number of *Scillas* are now in bloom, and I notice that *S. campanulata*—of which I have some thousands of bulbs naturalised beneath deciduous trees—is beginning to show its light blue bells. This species cannot be compared with the earlier *S. bifolia* and *S. sibirica* for beauty, though it is almost handsome in its great vigour. Its varieties *alba* and *rosea*, are interesting and worth growing.

My Poet's *Narcissi* are just breaking into bloom, and fortunately they need no recommendation, being among the few flowers which everyone admires. I do not expect my double *Narcissi* to bloom this month, as I planted them late in December. They will be welcome in May for their scent after the infinitely more beautiful single flowers have passed away.

I cannot understand how the *Snowflake*, which is now flowering, can by anyone be spoken of in the same breath as the single-flowered *Snowdrop*. The whole idea and essential grace of the latter flower seem to be absent.

The *Violets* are, of course, blooming. I grow several kinds, but to me the most beautiful of all is the common single-white. The beautiful form of the flower is changed into a shapeless mass in the popular and generally admired double kinds. The violet hybrids, the tufted *Pansies*, are beginning to flower, but their time is not yet, and I pick off most of the blooms as they appear.

The *Violet* has always been an honoured flower, as indeed its unique scent entitles it to be. Shakespeare makes numerous references to it, in almost every case specially indicating its perfume. To quote but two instances:—

"To gild refined gold, to paint the Lily,
To throw a perfume on the Violet,

Is wasteful and ridiculous excess."

"I think the king is but a man as I am;
The Violet smells to him as it doth to me."

Another sweet flower which has long received poetic homage is the *Wallflower*. Above a little stony bank, behind my *Escholtzias*, is a row of great bushes of these golden, "iron-brown" flowers. This colour and yellow seem to me to be the appropriate colours of *Wallflowers*; and I cannot imagine myself caring for a blue one. In the incessant search for novelty, florists are inclined to pay little regard to associations and traditions. A scentless *Carnation* or *Rose*, a blue *Wallflower*, autumn *Violets*, all seem to me to partake of the character of monstrosities and strangers. Christina Rossetti's sonnet has a wide range of application:—

"For *Violets* suit when home birds build and sing,
Not when the outbound bird a passage cleaves;
Not with dry stubble of mown harvest sheaves,
But when the green world buds to blossoming."

My north border is now bright with the flowers of several species of hardy *Primula*, in addition to the *Primroses* and *Polyanthuses* which I have everywhere. Among the best now in bloom are the sweet-scented little white *P. nivalis*, the sturdy and very floriferous *P. rosea* with bunches of bright red flowers, *P. denticulata* with dense globes of bright lilac, and *P. scotica*, a species not often seen, but exquisitely beautiful with its tiny yellow-eyed deep purple flowers.

My little greenhouse is now sweetly scented by the flowers of the *Auriculas*. Of those now in bloom, *Vulcan* and *Prince of Greens* are most admired, but all are beautiful as pot plants. *Auriculas* are particularly suited for pot-culture, being naturally of slow growth, set shape, and formal habit; whilst to get the full beauty out of the show varieties, it is of course absolutely necessary to grow them under glass.

Arabis, *Aubrietia*, and *Forget-me-not*, all help to brighten the borders with patches of violet, white, and blue, whilst several clumps of *Saxifrage* afford masses of white bells. Nearly all the plants now in flower are dwarfish in character, though the *Crown Imperials* and *Wallflower* are exceptions.

I must not forget my fruit-trees, which are now a mass of blossom. I look forward to a fair harvest of fruit this autumn. Every day my bees are hard at work gathering honey and pollen, and at the same time fertilising my flowers, and thus assisting the fruit-crop. I started with one stock of bees in the autumn. I have just divided it, placing three frames including a queen cell into a new hive. I hope that this will prevent swarming, but I have had no previous experience.

The *Thorns*, *Lilacs*, *Laburnums*, and *Deutzias*, are all showing their flower-buds, and, when these have expanded and fallen, the summer will be here. What a steady tramp, tramp it is! *Harry Roberts*.

ORCHID NOTES AND GLEANINGS.

CLARE LAWN, EAST SHEEN.

THE collection of Sir Frederick Wigan, Bart., which is well grown by Mr. W. H. Young, offers a good example of Orchid culture, worthy of imitation. Among the fine and rare plants noticed on the occasion of a recent visit, were *Laelio Cattleya* × *Digbyano-Trianæi*, a figure of which appeared in these pages, Jan. 1, this year; *Phalenopsis Schilleriana vestalis*, and many others. Each spring the display made with plants of *Cologyne Lowiana* is an extremely fine one, the strength and beauty of the plants increasing annually. They are treated "cool." Some large plants of *Cymbidium Lowianum* always occupy the highest points of the rockery, their graceful

foliage harmonising with the fronds and leaves of Ferns and other plants planted out around. At the present time they form a charming picture, with long pendent sprays of showy flowers. There are ten of these large plants which bear a total of 100 spikes, and 1625 flowers. The longest spike is 5 feet 6 inches in length, and bears thirty-six flowers. The largest plant has twenty-seven spikes. The plant nearest to the roof had its leaves frozen to the glass once, and it was not injured at all. A strong specimen of the greenish-yellow *C. T. concolor* bears two fine spikes.

The Phalænopsids in a warm, moist house, were giving promise of flowering abundantly; and *P. grandiflora aurea* and a few others were in bloom. In this house the *Cypripediums* from the tropics succeed admirably, and some of them are planted in beds, and many were in flower. Fine varieties of *Miltonia Roezlii* and *M. R. alba* were remarked in the house; also a richly-coloured *Cypripedium Mastersianum*, besides *Saccolabium ampullaceum*. In the intermediate-houses we noticed in flower *Cattleya Mendeli*, *C. Mossiæ*, *C. Schroderæ*, *C. intermedia*, *Lælia Latona*, *Tricopilia suavis*, and *T. suavis alba* with eleven flowers; *Sobralia macrantha* and *S. Ruckeri*, *Thunia alba* in several pretty specimens, *Oncidium ampliatus majus*, *Cypripedium Godefroyæ*, *C. concolor*, the last-named bearing three flowers on a spike. Among the *Dendrobies* in flower were some fine *D. Bensonæ*, *D. thrysiflorum*, *D. veratrifolium*, &c. In one of the houses a grand example of *Coelogyne pandurata*, on a 5-foot raft, and having four leading growths, was observed; in another, the specimens of *Lælia purpurata* were seen to be profusely furnished with flower-sheaths; and on a shelf near the roof a number of large pans of the different species of *Pleione* were growing vigorously. In the cool-house range a good display was made with *Odontoglossum crispum*, *O. Ruckerianum*, and other species; a fine lot of *O. Rossi majus* is in bloom, some of the plants having as many as twenty-five flowers. plants of the small-flowered (*Erstedii*) were bearing from twenty to forty blooms each. Others in flower were *O. elegans* with two spikes, *O. polyanthum*, *Disa tripetaloides*, and *D. Kewensis*; *Masdevallia Hircakiana*, *M. Benedicti*, *M. Chestertoni*, *M. Veitchi*, *M. ignea*, *M. ephippium*, *M. Lideni*, and other *Masdevallias*; also *Odontoglossum citrosum*, *Cattleya citrina*, the singular *Epidendrum hastatum*, and *E. Endresio-Wallisii*.

DENDROCHILUM FILIFORMIS, *LIPARIS LONGIPES*, &c.

Doubtless, in many collections of Orchids, the well-known *Dendrochilum glumaceum* will be in flower, or may have been during the past few weeks. The gracefulness of this species is alone a recommendation, and to those who are pleased with others, beside the more showy, I would say grow this *Dendrochilum* for spring-flowering; and also *D. filiforme* for the summer. The latter is a much rarer species, and will perhaps be considered by some persons the more beautiful. Others of the same genus are also well worth cultivating, but at the present time they are seldom met with in collections. Similar, in many respects, to the above is *Liparis longipes*, a plant possessing longer pseudo-bulbs than *D. glumaceum*, surmounted with two or three leaves of a bright green tint, and about 1 foot in length. Commencing to push in April and May, growth continues till the month of August, when the flower-spikes develop, whilst the pseudo-bulbs are finally swelling. By October the flowers appear on spikes of about 15 inches in length, forming an interesting sight. The spikes are almost erect, densely covered with flowers of a pale yellow, in fact, resembling those of *D. glumaceum* in size and colour, and withal, fragrant. The spikes last a long time in good condition. One plant that I had last autumn remained in an apartment at Bystock for a fortnight without suffering in any way. This plant came to us in a bundle of imported plants from Burmah, along with *Dendrobium Dalhousieanum*, and others; and so well did it grow, that nine spikes appeared the first year that it flowered, and the second year there were eighteen, whilst last year—the

third time—thirty-five spikes made it a very attractive object. This plant has now passed into the hands of a skilful Orchid cultivator. I anticipate an even greater advance by next autumn. *W. Swan, late of Bystock, Exmouth.*

THE USE OF ARTIFICIAL MANURES.

IS IT A CONTRADICTION, OR WHAT?—In the *Journal of the Royal Horticultural Society*, vol. xxi., Part I., August, 1897, p. 37, in a paper on "Artificial Manures," by Mr. J. J. Willis, I find the following:—"How much more useful these manures (stable and farmyard manures) could be rendered by an admixture with suitable artificial fertilisers."

various forms of dung in the soil, and the loss was greatest when the largest quantity of dung was used."

And on p. 482: "It now becomes of interest to ascertain what becomes of the nitrogen that loses its nitric form in the presence of dung." . . . "In every case it has been found that the nitrogen has been liberated in the elementary form."

P. 484: "There is thus no escaping from the conclusion that nitrates, whether naturally present in manure, or the soil, or when added in so-called artificial manures, are rapidly destroyed by organisms (bacteria) which are very abundant in dung, and are also present, though to a much less extent in soil."

Further on p. 484: "It was found that the crop was least, and the loss of nitrogen greatest, in the mixture that contained most straw." In other words, if you use nitrates in "conjunction" with dung, you may as well save the money

FIG. 104.—*ODONTOGLOSSUM WILCKEANUM*, PITT'S VARIETY.

(Shown April 12, at the Royal Horticultural Society's Meeting. For further particulars, see Report in *Gardeners' Chronicle*, April 16, p. 238.)

And on p. 42: "Artificial manures, therefore, are not recommended to take the place of farmyard or stable manure, but to be used in conjunction with them."

On the other hand, in the *Journal of the Royal Agricultural Society of England*, third series, vol. viii., Part III., No. 31, Sept. 30, 1897, now before me, I find the following in a paper on "Recent Experiments on Denitrification." On p. 477: "Notwithstanding the high position that artificial manures now take in the estimation of farmers in all parts of the world, it cannot be said that they have done anything to displace the use of farmyard manure, which must still be regarded as our most general and important fertiliser. All the farmyard manure produced in this country is still applied to the land, and artificial find their legitimate place as sources of plant-food on areas that the available supply of home-made manure is insufficient to dress."

But observe what follows on p. 480: "By a series of experiments and calculations, Maercker showed that from 12 to 47 per cent. of the nitrogen in nitrate of soda was dissipated through contact with the

spent in artificial nitrates, and leave it in the savings-bank, for, if all that has been written be true, you will obtain no advantage from the use of the additional artificial manure!

What is called "long manure," with plenty of straw in it, seems to be the most wasteful, for the additional straw is prolific in denitrifying bacteria, which dissipate the nitrogen in its elementary form, and so render the nitrate valueless.

However, on p. 485, this is stated: "Evidently, therefore, the denitrifying power of the dung is lost to a large extent by contact with the soil for two or three months."

"Wagner carried out a series of experiments, which also go to show that the denitrifying bacteria are much less energetic in old than in new dung."

In England it has been found that no appreciable increase of crop resulted when artificial manures, such as nitrates, were used with dung. And now German experiments appear to have solved this riddle. They seem to show that nitrogen is dissipated in its elementary form; that is, it is lost or wasted by contact with dung; and fresh dung, when

used in "conjunction" with nitrates, is far more wasteful than well-rotted dung, "for the reason that the denitrifying organisms so abundant in the dung instantly attack the nitrate of soda (or other nitrate, and also sulphate of ammonia, &c.), and dissipate the nitrogen in the elementary form."

I suppose we may infer that it would require the nodules of Leguminosæ to capture this elementary nitrogen again, and make it available for the growth of plants. The curious thing is, that purely phosphatic and potassic manures also fail to produce satisfactory results when used with dung; "but Wagner's experiments show that the negative results obtained, when mineral-manures are added to dung, are intimately associated with denitrification."

The conclusion to be drawn from all these experiments, if they are reliable, is first, that dung-heaps should be frequently turned, "so as to induce rapid

would be a hopeless attempt to try and persuade practical growers not to use them; the problem is, how and when to use them, when the soil needs some ingredients which these home-made manures do not contain.

This subject is so important, from not only an individual but also a national point of view, that the more it is ventilated, the more is the likelihood that we shall get at the bottom of the conditions needed for scientific agriculture and horticulture. *E. Bonavia, M.D.*

NARCISSUS LADY MARGARET BOSCAWEN.

THIS fine new Narcissus, which gained the award of a First-class Certificate R.H.S. on April 12 last, was raised by the Rev. G. H. Engleheart from *N. Hors-*

FIG. 105.—NARCISSUS LADY MARGARET BOSCAWEN: SEGMENTS SNOW-WHITE; CUP ORANGE.

fermentation, oxidation, and a high temperature" before using them; and second, not to use dung in "conjunction" with artificial manures, and especially with nitrates.

There can be no doubt whatever that farmyard and stable manures are very valuable and important fertilisers. The whole agricultural history of man, all the world over, from the most primitive times, furnishes evidence of this. The safest plan would, however, seem to be to use home-made and well-rotted manures one year without artificial manures, and only artificial manures the next year.

Artificial manures are trumpeted everywhere as the saviours of agriculturists and horticulturists, and no doubt if the soil wants these ingredients, and if the crops to be grown require them, they must be of advantage; the question, however, remains as to how and when these artificial manures should be used.

Farm and stable manures have for ages given satisfactory results, under certain circumstances, that it

field by pollen of *N. poeticus ornatus* (fig. 105). The effect of such a cross is often, as in the flower here shown, the shortening and expanding of the crown of the Trumpet Daffodil without infusion of colour from the poeticus. The great accession of size and stature may be attributed to the employment, as is the raiser's custom, of differentiated parents, i.e., in the present case the pollen used was that of a flower not grown in his own garden or vicinity. In form and robust habit, Lady Margaret Boscawen may be described as of the Sir Watkin class, but its remarkably broad flat segments are of clear white. The great size of this flower, its vigour and freedom of bloom, and its length of stout stem, must render it a coveted Narcissus, not only for the amateur collection, but for market work. It is named after the wife of the Hon. John Boscawen, who is well known in connection with the advancement of horticulture in his county of Cornwall.

"LA MAISON RUSTIQUE."

(Continued from p. 229.)

THE next two chapters are devoted to the consideration of Beets, Blites, Orache and Spinage. These include a large number of plants, but the names were at one time strictly confined to a lesser number. The first-named, "Bette and Jotte" was what we now designate "Beetroots," and comprised at the period under review the white-rooted, the black-rooted, and the red-rooted "Beetes," sometimes referred to the above, more often to *Chenopodium Bonus Henricus*, in earlier times called *Betin* or *Betyn*. In France one of its names was "epinard sauvage," or "Wildspinach." Blites (*Blette*) included *Chenopodium album* and *C. rubrum*, both of which were cultivated. Lightfoot in *Flora Scotica* mentions having seen them eaten in Islay when in company with Pennant he, in 1772, visited the Highlands of Scotland. Of "Orache" there were two kinds, white and red-leaved, and these are varieties of *Atriplex hortensis*. Of "Spinage," according to our author, two sorts were grown, and chiefly for use during Lent; of these the one was known as the male, the other the female, the latter so named because it bore no seeds. This curious belief that it was the male and not the female plant that produced seeds was held by everybody. One of the very commonest examples is furnished by Hemp, and it was not till Phillip Miller pointed out the mistake that it was recognised as one. The female Hemp was called "Fimble," and the male "Carle" (Worlidge calls it *Karle*), and the latter was carefully looked after for seeds; or as Tusser puts it, "The Fimble to spin and the Carle for seed."

Leeks were cultivated in much the same manner as now. Onions were an important crop. Two sorts, the red and the white, the latter the more appreciated, were grown. It was "the countryman's meat," and "he that eateth every day tender Onions with honie to his breakfast shall live the more healthful." Chibols and Chives are noted as good in salads; then a long chapter follows on "Garlicke," which is called the countryman's "treacle in the time of plague." Treacle here has the old meaning of a certain composition used in sickness, and has nothing in common with what we know as that delectable semi-fluid. It is, however, curious that the ancient belief in the efficacy of treacle has been transmitted through long centuries, and still rests upon the article which bears its name. In some parts of France, Garlick eaten with fresh butter on the 1st of May was considered a hopeful method of securing immunity from sickness for the succeeding twelve months.

Purcelaine, Rouquette, and Targon (*Tarragon*) were all salad plants in request. "Tarragon," Surfeet informs us, "is made of linseed pricked in many places of the head of a red Onion, and put into well-manured earth." Smallage and "Chervile" are treated together. The former is noted as being of value as "a physic herb." In due time it became Celery. "Coq" (*Costmary*) and "Sano Monde" (*Avens*) were both held in much esteem as aromatic herbs. It seems strange now that so common a wayside weed as the latter should have been cultivated in gardens. The French, however, as well as the English, held it in high esteem, and it was called *Benôte*, or the Blessed Herb, "Herb Bennet" being a corruption of the first name. From the roots smelling strongly of Cloves it was also designated the Clovewort, anciently *Caryophyllata*, and now the well-known *Geum urbanum*. Asparagus, called "a delicate fruit," is followed by a chapter on Cresses. In the French original three kinds of Cresses are described; in the English, too, garden Cresses and Water-cresses. The former is made to include the "Cresson d'Alenois" and "La Berle," which last is said to grow with the Cresson d'Eau (Water-cresses), and in old English, "Carsyndills." The Berle mentioned here is *Veronica Beccabunga*, commonly known as "Brooklime," the "Blue Cresses" of the Ettricks shepherds, "Bonnie Kilmeny." At one time this was eaten freely along with Cresses. Now, many consider it poisonous. Miller explains how this has come about, through the creeping Water-Parsnip—*Apium* (*Sium*) repens—having been gathered for the Water-cress, and eaten with bad effects. This plant in *La Nouvelle Maison Rustique* is called "Berle or Sium," and we still find "Berle" in French dictionaries translated "Sium or Water-Parsnip." It is a curious instance of misappropriation of name and characteristics. Navets, both white and yellow, were largely cultivated. Turnips were too coarse for high-class tables, but in some parts of France the inhabitants actually lived on them, and

ate nothing else. It is noted that Mustard ought always to be eaten with Navets. Radishes follow, and were a favourite esculent. Sweet Radishes were produced when the seeds, before sowing, were steeped for a time in honied wine, and those sown in the usual way were rendered less bitter if occasionally watered with salted water. Sennie (Mustard, which includes Charlock), was an important crop, the seeds only having been used. Our author states, it "sprang very easily, inasmuch as it is hard to destroy it where it hath been once sown." Hence the name *Sen vie*, "always living."

A few other vegetables are noted, and a long list of physic herbs, many of which we reckon now as weeds. Among these, however, occurs a long dissertation on Tobacco, over the healing qualities of which the writer is quite enthusiastic. These we cannot transcribe. But the reader is assured, as a fact not to be disputed, that "the inhabitants of Florida feed themselves a certain space with the fumes of this herb, which they take at the mouth by the means of small horns." Further on he adds that "the fumes of this herbe maketh men somewhat drunke, and by that reason call it a kind of yellow Henbane." Sarsaparilla, under the name of Meoachan, a kind of "Lizeron," is also praised very highly for its curative powers. *R. P. Brotherston.*

To be continued.

REMINISCENCES OF GHENT.

(Continued from p. 259.)

BRUGES.

M. Vincke-Dujardin's Nursery.—A visit to the great establishment at Scheepsdale, Bruges, revealed a nursery in good order, and of more than usual interest by reason of the splendid condition of the inmates of the dozen or more long ranges of Odontoglossum-houses. These plants have been in fine condition for some years, and they are not declining as some persons supposed they would do; the specimens of *Odontoglossum crispum* and other Odontoglossums in *M. Vincke-Dujardin's* houses are magnificent, affording another proof that Orchids need not degenerate if proper provision is made for their culture, and the plants are carefully tended.

The plan of the great blocks of houses running right and left of the central transept is of the best possible to secure good ventilation, without causing cold currents of air for the houses, although forming separate houses above, are open underneath the staging, and there are no dividing walls.

At the time of our visit the fine varieties of *Odontoglossum crispum*, *O. triumphans*, *O. luteo-purpureum* and other Odontoglossums, *Miltonia vexillaria*, *Cattleya Mendeli*, *C. Lawrenceana*, *C. Schroderæ*, *Vanda tricolor* and other showy species, and some good *Cypripediums*, made a beautiful display. Among large batches of plants not in flower, yet remarkable for the high state of culture evidenced, were many varieties of *Lælia anceps*, *L. purpurata*, and *Cattleya labiata*.

Palms of species suitable for decoration, and especially *Kentias*, which were observed from the tiny seedling up to the giant specimen abound, and all were in fine condition, clean, and well-grown; as were *Bromeliads*, likewise *Anthuriums*.

In the open ground, and planted in tubs, a very large number of sweet Bays, chiefly standards, in all stages of growth were remarked; some of the larger specimens being of great age, a few having been in the possession of the family for upwards of 130 years, tended and venerated as household treasures. With regard to these useful decorative trees, it is a mistake to suppose that their cultivation entails but little trouble. On the contrary, they require much care in storing them away in shelters in the autumn before frost injures them, to see that they are not placed outside before all risk of frost has passed; then the annual pruning of every point, the constant attention in affording water, and in many other respects these plants requiring much care.

M. Ed. Deryghere Van Compernelle.—In this compact and well-kept nursery, whose English-speaking proprietor is so well known to British nurserymen visiting Belgium, there are always

numbers of plants remarkable for excellence of cultivation, or which are out of the ordinary run of nursery stock. At the time of our visit we found there numerous pretty plants of *Livistonia rotundifolia* in several sizes, and all of uniform good quality; another special feature was several housefuls of *Phoenix canariensis*, a variety of comparatively dwarf and dense growth, and said to be a great favourite for the decoration of dwelling-houses. *Raphis aspera* and *R. a. nana* were two striking Palms, which multiply at a very rapid rate by offshoots from the base.

Other noteworthy stock comprised *Aspidistra lurida variegata* and seedling *Cliveias*, with very fine flowers. In the open ground, Lily of the Valley for selling in clumps for forcing are well and extensively cultivated. The view of some old ruins on the other side of the moat, and around which the yellow and lilac Primroses and other wild flowers were luxuriating prompted questions as to the former history of the place, and we were informed that where the nursery now stands was the cemetery adjoining a monastery which stood there about the year 1800 A.D.

L. LINDEN ET CIE., MOORTEBEEK.

An unusually interesting group of Orchids from Brussels, exhibited at the last meeting of the committees of the Royal Horticultural Society, was awarded a Silver-gilt Medal. Every plant it contained was remarkable for the perfect cultivation it presented, and for its value as a desirable variety. Exactly one week previously, we had seen most of the same plants, and many thousands beside, in the houses at *M. Linden's* Orchid establishment at Moortbeek, some 4 miles to the west of Brussels. We had travelled from Ghent, a party of five Englishmen, and as soon after arriving at Brussels as was possible, we presented ourselves at l'Horticulture Internationale in the Parc Leopold, where there was much to interest and admire. But before the Orchid-houses there had been thoroughly inspected, *M. Lucien Linden* telephoned from Moortbeek that there was much more to see at that place, and invited us to proceed thither at once.

Those who have visited the magnificent City of Brussels of late years will know that we might have proceeded thence by the excellent trams, that open up the beautiful boulevards and principal streets of the city and suburbs. Indeed, the systems of tramways form one of the most striking features a visitor to the city can remark. Time being short, however, we proceeded in cabs over roads that seemed to traverse most of the few hills Belgium possesses. The route is a very pleasant one, and the roads generally are of great width. As we approach the Chaussée de Ninove it is seen that the nursery is situate perfectly in the country, on a plateau where one would expect the air to be—as indeed it is—comparatively free from urban influences.

The Moortbeek Orchid-houses consist of a large central glass building, running at right angles from the road, and fourteen span-roofed divisions opening into this, seven upon either side. Several of these were filled with Odontoglossums—such plants as are worth travelling some distance to see. These healthy, vigorous-growing plants, more than surprised our party, although each of us were familiar with the best collections in England. Yet, it is only two years since this establishment was built, and therefore the specimens had been established for a very short period since importation. We may explain that the seven houses were connected in the typical Belgian method, the span between each division only descending to about 4 feet from the floor. By stooping a little, one could see the plants right away through, and we thus saw a collection of about 53,000 Odontoglossums. From every point of view these were satisfactory, whether one looked at the plump, solid pseudo-bulbs last made; at the thick, stiff, partially purple-coloured foliage; the strong, vigorous growths just breaking away; or the forest of spikes that will soon bear a display of blossoms. The species *O. cirrhosum* especially was remarkable for its wealth of flower-spikes. A batch of them occupied one side in a division, and we have never seen this Orchid happier.

The spikes were very strong, some were 2 feet or more high, and many of them in bloom, exhibited varieties of exceeding value. But our attention was soon absorbed by the collection of *Miltonia vexillaria*. These were a picture, the young growths developing as freely as a vigorous *Cypriped* might be expected to do; there were no crippled leaves, no sign of spot, or other result of unsuitable environment. One of these since shown at the Drill Hall, was a magnificent picture of successful cultivation and excellence of variety. It has been named in remembrance of the late *J. Linden*, and had six spikes bearing thirty-two flowers, some of these about 3½ inches across, and rich rose-coloured. Of *Odontoglossum crispum* we can only speak in the same appreciative terms. The plants throughout were in every sense perfect. So much so, that we asked *M. Linden* if he had any explanation he could give. Had there been any manure used? "None whatever," replied *M. Linden*, "there is nothing unusual in the treatment. The plants have been given nothing but peat, sphagnum-moss, and water, but the water of the district is doubtless peculiarly suitable to Orchids." Of the many particularly fine forms of *O. crispum*, one known as *Comte de Flandres* had large flowers of exquisite form, each sepal being heavily blotched, and the petals white. Then there were many pretty Odontoglossums, that were evidently hybrids between *crispum* and *Wilckeanum*, and *crispum* and *Hunne-wellianum*, and others whose pedigree it was difficult to declare. *O. Princess de Canaries* was such a hybrid; it had bright canary-yellow coloured flowers, with purple-red spots, and a white fringed lip. Some exceedingly pretty forms of *O. Wilckeanum* were remarked, most of them perfectly distinct, and bearing names, but we had not time to note carefully each of these. A word is deserved by a plant of *O. luteo-purpureum luridum*. The spike carried sixteen fine flowers, which were remarkable for the prevailing colour of deep brown, being strikingly distinct in this respect. A very lovely variety of *O. Pescatorei* was named *Roi Leopold*; the flowers were large, pure white, and each petal and sepal bore several violet or purple blotches towards the points. It was impossible to linger more, even to admire the lovely forms of Odontoglossums, and we were soon face to face with the *Cypripeds*. In the first place was a magnificent group of plants of *C. Lawrenceanum*, presumably the greater part of a thousand in number. At first glance they looked like a group of ornamental foliage plants, they were so vigorous and the marking so distinct. Against this view, however, were the numerous flower-spikes and large blossoms, the spikes in many cases being about 20 inches high. We afterwards went to inspect the many hybrid *Cypripeds*, and the recognised species and varieties. One of the most beautiful hybrids was *C. × Lebaudy-anum superbum*. The sepals were wide, and the ground colour white, marked much with chocolate, petals long, and twisted a little, green at base, spotted with purple, points exclusively purple, the prevailing colour of lip, green. *C. Rothschildianum platytæ-nium* was observed to be a very striking plant. The *Cattleyas* generally were only showing sheaths, but from the strength and number of these, it is certain a fine show will be made a little later. Those already in flower included some excellent forms. *C. Mendeli* especially was very fine. A variety named *The Pearl* was almost white, but one could easily detect a faint blush, for which the flower was prettier than a pure white would have been. *Cymbidiums* looked as well as the species already noticed, and *C. Lowii superbissimum* was a very large richly-coloured form of this popular plant.

NATURAL ADVANTAGES.

The continued anxiety of the Englishmen to find an explanation of the apparent ease with which Orchids (and especially Odontoglossums) are cultivated at Moortbeek, led us to make many enquiries, but all the explanation forthcoming was that of suitability of site. Said *M. Linden*, "I believe there is not a better site in Belgium for the cultivation of Odontoglossums than is Moortbeek." How came *M. Linden* to go there? Here is the answer as nearly

as possible as we received it. Immediately opposite the establishment is a gentleman's residence, and M. Linden had noticed that the *Odontoglossa* in this garden succeeded better than in his own, although they were cultivated under M. Linden's direction. In conversation with this gentleman, who was also the owner of the land where M. Linden's establishment now is, M. Linden expressed his conviction that the secret lay in the water or site, or both. The gentleman's reply was, "Take a lease of some land opposite, and see."

This was done, and the result in two years is such that one would not realise unless he saw it. We examined the boilers, which are horizontal tubulars, and also two new houses not yet filled with plants. Everything was skilfully done, and nothing without a reason, but there were no great differences from

generation from seed. A good blossom measures $2\frac{1}{4}$ inches, and in special instances of $2\frac{1}{2}$ inches in diameter have been remarked. The plant shown at the Drill Hall on April 26 last, had been reared in natural soil, without any fertilising food whatever. It was exhibited at the shows of the Royal Horticultural Society, in April of 1891, April of 1894 (awarded "Merit"), in 1896, and in 1897.

The plant is obtainable of Mr. G. Parr, Estate Office, Hampton Court, Leominster.

OUR TREATMENT OF A SWAMP.

A PORTION of the great pool formed here, about 140 years ago by Lancelot Brown, got so silted up at the narrow end by the inflow of a muddy stream, that it left the breadth we have to deal with—200

the problem given to us to work out. The idea of introducing a dredging-apparatus and spreading the mud on the land adjoining was abandoned on account of the expense; so the next best and cheapest way of dealing with it we thought to be to separate the land from the water, by forming long ridges of land, the spaces between being filled in by canals of water. The ridges average from 2 to 3 feet above the level of the water area, the water depth to about the same. The water in these canals stands exactly at the same level as the surface of the water in the great pool; the water of which was, of course, lowered during the time we were engaged in this, to me, very interesting operation.

In times of flood, or as a Scotchman would put it—when there was a "spate in the burn"—the water, as I have already said, overflowed the entire space we have to deal with. To obviate this we resorted to the canal-ridge system, connecting the canals with the inflow of the feeding-stream; this arrangement gives a nice gentle flow through all the canals, preventing any chance of stagnation, and also the danger of any further overflow.

Within the space we had to deal with, there lay a couple of islets left there by Brown during the time he was engaged forming the great pool of about ninety acres, on one of which there is a heavy plantation of Scotch Fir, also Beech and Larch, which is strong evidence of what an extraordinary weight of timber a small space will yield. On the other islet are six nicely-grown Hawthorn-trees, which, when in bloom in May, are a picture worth looking at, having an undergrowth of Cow-Parsnips, Lords-and-Ladies, Nettles, &c. These botanical specimens are now giving place to a liberal sprinkling of Narcissi, Snowdrops, Crocus, Iris, &c.

Having given a description of how we separated the land from the water, by which stroke we secured over the space, and also in the neighbourhood, a sweet healthy smell instead of the pestiferous one we displaced, I come now to the question as to how this singularly arranged space of water and land should be planted. At present it is simply canals of water and ridges of land. We propose planting the canals with some of those new hardy hybrid *Nymphæas*; the only one of these we have is that of Cape Cod variety, which I had a few years ago from my friend Mr. Brydon, of Yarmouth port, who is so successful in flowering many varieties of *Nymphæa* out-of-doors, including the *Victoria Regia*. A photograph Mr. Brydon sent me I enclose, but only as a specimen of outdoor culture in a proverbially cold windy district.

The ridges we purpose planting partly with *Rhododendron*, varieties of *Spiræas*, ornamental Willows, deciduous Cypress, Pampas-grass, Iris, variegated Elders, Acer, &c. It will be needless to plant Bamboo, as the common Reed grows here in great luxuriance; the difficulty is to keep it within bounds, as it leaves its swampy bed and marshes upwards and onwards on to dry land, coming up even through hard gravel walks. If any of the readers of the *Gardeners' Chronicle* would kindly give a supplementary list of plants they could recommend for the purpose of planting the ridges, I should be pleased and grateful.

My treatment of the subject has so far met with the approval of the Earl of Craven, that his lordship desires another and greater breadth of swamp to be similarly treated as soon as opportunity permits; though it seems a pity, after all this labour and expense, that these canals, by the continuous inflow of mud brought down by the stream, will, in the course of a few years, be again silted up, necessitating a fresh digging out if they are to be kept free. To obviate this, I have surveyed an entirely new route for the stream, which, when the river-bed is dug out, will be a full mile long, and will carry the water, all the mud and sewage brought down therewith, completely past and beyond the outlet of the great pool. The pool would then be fed from the stream only when the water was clear; when foul, it would be sent down the new cutting. There are sundry springs along the shores of the pool, which would help to supply it with fresh water. This suggestion is

FIG. 106.—GIANT PRIMROSE "EVELYN ARKWRIGHT": COLOUR PRIMROSE-YELLOW.

other growers' houses to account for the success. We may say, however, that the stages are not solid, but air, heat, and moisture can circulate upwards amongst the plants. In the fourteen houses we have referred to, a tank of water runs along the length of every alternate one, consequently water can be reached from each, and the moisture from them, of course, circulates through the whole range. Thus we saw Moortebeek, and our experience is well given in a remark made by one of our party as we drove back to Brussels, "I have had no such lesson in gardening as I have had to-day for a very long time." R. H. P.

THE GIANT PRIMROSE, "EVELYN ARKWRIGHT."

THIS Primrose (fig. 106) was found wild in Dinmore Wood, Herefordshire, in 1887, and the stock raised from the original plant, has kept its character to the third

yards long by 90 wide—in a state which could neither be described as being land or water. During summer evenings, especially when the weather was hot, the surface of this unpleasant-looking swamp gave off most evil miasmatic effluvia, and bordering as it does on a portion of the pleasure-ground, was by nervous people studiously avoided.

The river-bed was almost grown up, what with the mud brought down by itself in times of flood and the encroachments of the common reed, *Arundo phragmites*, several species of the *Carex* genus, and many other aquatic and marsh plants of the Midland counties flora, in which the pool and its shores are so exceptionally rich, that the lines of Burns were sadly inappropriate to the case when he says—

"Time but the impression stronger makes,
As streams their channel deeper wear."

The question of how to make this portion of the pool healthy, and at the least possible expense, was

thoroughly approved of, and will in course of time be carried out, though not, perhaps, until after I may have passed away to the "land o' the leal."

A portion of the pool here was cleaned out in 1863, and on several occasions previous to that date. The operation is an expensive one, and as time goes on the expense becomes greater. On this account, I am afraid many of our lakelets are being allowed to silt-up, and in this state are a great deal more unsightly than if they had never been formed at all.

Wisdom is only got by experience, and it is always an easy matter to be wise after the event. Had it been foreseen at the time these pools were being formed that they would so soon become silted-up, necessitating almost the cost of remaking to clean them out, the first cost of making an independent river-bed or by-pass might have obviated much of all this. Of the finny occupants of these waters, of its feathered fauna, of its aquatic and lake-shore flora, I may some day speak in another chapter. *W. Müller, Combe Abbey, Coventry.*

FLORISTS' FLOWERS.

TOO-MUCH-ALIKE CHRYSANTHEMUMS.

It has become necessary for the National Chrysanthemum Society to adopt a similar practice to that followed by the National Rose Society, and prepare as an instruction to the exhibitors at their shows, lists of varieties which so nearly approach each other in general appearance as to justly come under the head of too-much-alike varieties. The resolution adopted by the executive committee was as follows:—"Experience having shown that several Chrysanthemums classed as distinct varieties are much alike when staged for competition, it has been found advisable to lessen the risk of duplicates being shown in classes for cut blooms in which they are required to be distinct; therefore, in the cases of varieties that at certain stages of development closely resemble each other, the blooms exhibited must in classes for distinct varieties, be sufficiently diverse, so as to be readily distinguished by the judges. It was referred to the Society's classification committee to draw up this list, and they have selected the following as so nearly approaching each other in general appearance that they must not be shown on the same stand:—

Incurved Varieties.

C. H. Curtis	John Salter
Major Bonaffon	Mr. Howe
Duchess of Fife	Lady Dorothy
Mrs. Airdrie	Charles Gibson
Empress of India	Lord Alcester
Lady H. St. Clair	Princess Imperial
Mrs. Cunningham	Miss M. A. Haggas
Snowball	Richard Parker
White Queen	Mrs. Heale
Golden Empress of India	White Princess
Bruce Findlay	Mrs. George Rundle
Golden George Glenny	Mrs. George Parnell
Mrs. Dixon	Princess of Teck
Mrs. C. H. Glover	Charles Shoesmith
John Doughty	Christmas Number
Mrs. Robert Mudie	Princess of Wales
Bronze Queen of England	Beauty of St. John's Wood
John Lambert	Mrs. Heale
Golden Queen of England	Queen of England
Emily Dale	Blush Queen of England.
Emily Dale Improved	

Japanese Varieties.

G. J. Warren	Sunflower
Yellow Madame Carnot	Stanley Yellow
Mrs. C. Blick	W. Slogrove
Mrs. Richard Jones	Improved W. H. Lincoln
Pride of Madford	T. Selwood.
Beauty of Teignmouth	

This report is published in the Schedules of Prizes just issued, and should have the close attention of intending exhibitors. *R. D.*

THE WEEK'S WORK.

THE FLOWER GARDEN

By H. WALTERS, Gardener, Eastwell Park, Ashford.

The Rose Garden.—All varieties of Tea Roses should have been pruned ere now, and the mulching which was placed on the beds or borders in the autumn lightly forked-in, taking great care not to injure the

roots of the plants. Let all growths of climbing Roses on chains or arches be secured from time to time as required; also fasten with rails and shreds, willows, or tarred-twine the shoots of Roses growing against walls, fences, espaliers, so as to prevent injury by wind. The recent rains have had a very beneficial effect on the growth of Roses, and hybrid perpetuals in many gardens are making robust growth. Let a sharp look-out be kept for the Rose-maggot, which must be collected by hand; and sprinkle with tobacco-powder all shoots infested with green-fly. If the Rose-garden is under grass let the latter be mown and the edges of the turf neatly trimmed; and the various walks well rolled, so as to make them comfortable to pedestrians. Gloire de Dijon and other early-flowering Roses, in sheltered places are already showing flower-buds, and if genial weather should continue, blooms will be expanded in a week or two, rendering the Rose garden of much interest, the first Rose being as attractive to most of us as the last one.

General Remarks.—The plants and bulbs usually associated together in the spring garden will now be in full bloom. The Myosotis, with its ever pleasing blue; the bright pink of the Silene; the Wallflowers, with their golden-yellows and dark reds, and their delicious perfumes; the Tulips, with their vivid hues, and many others, all tend to enhance the beauty of the garden. This is the season for taking notes of desirable alterations and changes to be carried out next year, and observing suitable harmonies and contrasts of colour; what plants make suitable carpets for flowering plants, &c. The planting of Calceolarias should be done as early in this month as possible, using great care in the planting, and endeavouring to preserve intact the balls of soil and roots when lifting and planting them. Let them be firmly planted, and sprinkle them overhead every evening when the day has been dry with a fine rose-can or the syringe. This may be carried out for a fortnight after planting, and be sure that the soil of the bed is soaked with water previous to lifting the plants from it. Continue to sow annuals, and to prick out all plants which require it. The gradual hardening off of many of the subjects used in the summer flower-beds will soon have to be commenced. This simple operation must be carried out with great care, as too great or too sudden exposure will ruin many plants. I am aware that this matter, like many others in connection with gardening, is considerably easier to write about than to practice, for most of us have few proper means of hardening off plants by degrees. A satisfactory shelter can be erected with a few posts driven into the ground, and battens fixed across the space to support garden mats or Frigi Domo, with broad boards nailed round the enclosed area. The difficulty to be encountered is the removal of the coverings by the wind; but this can be got over by passing cords over them, and securing these to the posts. Plant out Stocks this month, and do not leave them in the frames till they become drawn. Choose a showery day for planting-out, or afford water copiously, never minding how small the plants are at the time of planting, providing they are healthy, and have been thoroughly hardened-off; and take care to afford the plants water previous to lifting them. Stocks like manure and deep digging, but do no good in poor soils. Zinnias are now commonly grown for bedding-out, and should be afforded water in not too great abundance, being very apt to damp-off. If the stock of Alternantheras is insufficient, cuttings may still be taken, and dibbled in to sandy soil above a half-spent hot-bed, and allowed to remain there till wanted for planting out, hardening them off after they are rooted.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Runner Beans.—The soil, having acquired a little warmth, the first out-of-doors sowing of Runner Beans may be made in drills 3 inches deep, and from 5 to 6 feet apart on trenched, and well-manured land. In private gardens, it is better to furnish sticks for the Beans to climb, as then the crop is larger and the pods clean. The plants can, however, be grown dwarfly, so that sticks are not actually required—which is done by nipping off the points of the shoots every eight or ten days during growth, beginning to nip them when a height of 2½ to 3 feet has been reached. If very early Beans are desired, seeds may be sown in 6-inch flower-pots, placing these in a structure having a temperature of 45°, and gradually harden-off the plants preparatory to transplanting them in the open. For general crop-

ping—Painted Lady, Champion Scarlet, or Carter's Jubilee, are the best. To have fine pods for exhibition purposes, it is best to sow in trenches prepared as for Celery, the varieties, Sutton's Best-of-All, or Veitch's Mammoth Scarlet.

Broad Beans.—When the stems of early Mazagan Bean have reached 2 feet in height, and begun to show blossoms, let them be topped to such an extent as to leave a sufficient number of pods on the stalks to form a crop. This topping not only makes the pods swell faster, but it forwards them by at least eight days as compared with untopped stalks. If the ground is dry, afford plenty of water at the root; and during the present month sow once again.

Outdoor Tomatos.—The plants raised from seeds as directed in former Calendars will soon be sufficiently hardened off for planting on outside fruit walls, in the spaces between the trees, and in warm positions away from walls. If the soil is exhausted, let a little rotten manure be mixed with it before setting out the plants. Place a stake to each, and stick a few evergreen twigs around as a protection against cold. Tomatos in the open air in this country must be kept to one stem, and when four or five clusters of fruit are set, nip out the leader, and repress all lateral shoots. As the plants progress, afford manure-water occasionally, or apply a mulch of partly-decayed dung, but do not aim at great robustness in the plants, moderately strong plants being the heavier croppers.

Gherkins and Cucumbers for Pickling.—The surest method with these is to sow the seeds in flower-pots, one or two in each, placing the pots in a cold frame or handlight, not forcing them in any other manner, as the best pickling fruits are produced without the aid of a hotbed from the first. The plants should be ready for planting on to a warm border towards the end of this month or in early June. Let the stations or ridges be prepared to receive the plants betimes, and afford the plants a shift rather than let them become potbound if the weather is unfavourable for planting.

Remarks.—Thin out Parsnips, Turnips, and Carrots, and draw some soil over the Potato-haulm that is showing above-ground, to prevent injury by frost; and on the first fine day pass the Dutch-hoe between the rows of spring-sown Onions. Spring-raised plants of Brussels Sprouts, Cauliflower, and early Cabbage should be planted out during showery weather.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Ceologynes.—Plants of the well-known *Ceologyne cristata* and its varieties, *Lemoniana*, *Chatsworth*, *maxima*, and the white variety *hololeuca alba*, having now rested sufficiently long, and commenced to grow, additional rooting-space may be afforded them, and inconveniently large specimens, as well as those that are bare in the centre, may be divided and repotted. It is not, however, advisable to disturb these plants at all if they are in a satisfactory condition. The pseudo-bulbs that have got over the edges of the pans or pots may be severed with several of the older bulbs to which they are attached, and potted up so as to make one or several compact potfuls, and the old plant, if not further disturbed, will break and send out strong young growths. For repotting *Ceologynes*, make use chiefly of good turfy loam and peat, sphagnum-moss in proportion equal to these two, mixing all the materials with clean crocks, and be sure that the drainage is perfect, great quantities of water being necessary in the growing period. If a plant has been disturbed at the root, the pseudo-bulbs will often shrivel, but the plant must not be deluged with water with the idea of inducing plumpness; too much water at such times being death to the old roots, and a cause of loss of health. Instead of heavy watering at such times, let the plants be syringed occasionally, and the surfaces and sides of the pots damped three times a day, and carefully protect the plants for the time being from strong sunshine. When growth is developing nicely the roots are active, and water may then be gradually increased in quantity. Plants of *C. Massangeana*, *C. flaccida*, *C. tomentosa*, *C. barbata*, *C. graminifolia*, *C. conferta*, *C. ocellata*, *C. speciosa*, *C. elata*, *C. Cumingi*, *C. sparsa*, *C. corrugata*, *C. Rossiana*, *C. Thuniana*, *C. Gardneriana*, *C. odoratissima*, *C. corymbosa*, and *C. glandulosa*, now making a start, may be repotted. For the first three species, hanging baskets are the best, as in these the racemes are seen to more advantage than in pans. All the *Ceologynes* mentioned above thrive in a shady part of the interme-

diate-house, rooting freely in well-drained peat and sphagnum-moss. The fragrant *C. Sanderiana*, on the completion of the new pseudo-bulbs, should be placed in a cool-house and kept moderately dry at the root till growth begins anew, and if a slight shrivelling of the pseudo-bulbs occurs, no harm will be done. The tips of the young breaks of *C. conferta* are sometimes covered with a gummy substance, which should be washed off, or the leaves will not expand.

HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Peaches and Nectarines.—The disbudding and stopping of the shoots should be completed without loss of time. In disbudding, the best shoot at the base of each bearing-shoot of the current year should be left as the bearing-shoot of next year, and these shoots be tied with a broad piece of matting in the direction they should take. If possible, they should be situated on the upper side of the bearing-shoots for fan-trained trees. Any Peach-trees that have been trained in previous years in other methods, should be gradually altered till they assume a symmetrical fan-shape, and provision can now be made by leaving the terminal growths at full length on all properly-placed branches where room for extension exists; stopping the points of those that are situated on the wrong side of the main branches, and all weak shoots of which it is not advisable to allow the extension. In disbudding the Peach, some gardeners pull off every shoot except the one at the base of the shoots and the terminal growth; this, however, denudes the tree too much of foliage at a critical time, that not enough is left to keep the fruit progressing, and if unfavourable weather should occur a large proportion of the fruit may drop off. It is a more prudent proceeding to leave some of the current season's shoots at intervals of 6 inches along the branches, stopping them at the fourth leaf if they are not required for laying-in. The Peach or Nectarine on outside walls seldom requires more than one piece of young wood to be left on each branch, unless the tree be young and vigorous, when two may be left to grow in addition to the terminal; and these two should be situated at about 18 inches apart along the branches. In Peach culture it is very necessary to guard against overcrowding the trees with young wood, which eventually shades the fruit, and robs it of colour and impairs flavour. Moreover, the bearing-wood for the following season is rendered weak and immature. Blistered leaves should be removed without delay, as they are apt to harbour insects that are very difficult to dislodge. In the case of trees badly blistered their removal must be gradual. Tobacco-water forms the best remedy for green-fly; but as its strength varies a great deal, it should be tested upon some young shoots a few hours previously to using it on the trees. One fluid ounce to one gallon of soft water is usually sufficiently strong. The effect of a too strong solution is to fetch off the leaves and the fruit. Royal George is a variety that is much subject to be attacked by mildew, and whenever this parasite appears, the affected trees should be syringed with a weak solution of Gishurst Compound-soap not exceeding 2 oz. to 1 gallon of water, allowing it to remain on the leaves. This kind of soap is one of the best antidotes for red-spider. All insecticides should be applied to the trees in the evening, and in fine weather, for the foliage of the Peach being very tender at this date, is easily injured. Nets and covers should still be put over the trees at night, cold winds, especially those from the east, conducing to mildew and the attacks of aphides. Remove all undersized fruits where set very thickly, also such as are badly placed, leaving the largest at 3 inches apart.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Tree or Perpetual Flowering Carnations.—The plants of such varieties as Miss Joliffe, Winter Cheer, and others raised from cuttings last year, and now standing in 6-inch pots, will be ready for shifting into others 2 inches larger, and those raised from layers should be planted in large 60's or 48's without delay, placing them afterwards in a cool, light, airy frame, affording water at the root with great caution, and pinching the points of the shoots in order to induce more bushiness. Cuttings struck in thumbs in heat should be hardened off quickly, and shifted into 60's, large or small, according to requirements, as soon as well-rooted. It is not too late to strike cuttings of the winter-flowering varieties.

The Margaret Varieties of Carnation are very useful in the autumn, winter, and spring, either in pots

for decoration or planted out in a pit for cutting purposes. Seedlings of these, when furnished well with roots, may be potted into 60's, preparatory to planting them in the cold pits, at 15 inches apart each way. It is advisable to grow two or three successional batches of these plants.

Campanula calycanthema.—As a pot plant the Canterbury Bell is well worthy of cultivation, the flowers of the single and semi-double varieties lasting a long time in good condition. Seed may now be sown in pans, and the latter placed in a cold frame to germinate. When the seedlings can be handled conveniently, prick them off an inch apart into other pans or into boxes; and when they possess a good ball of roots plant them on to a border, there to remain till the autumn, and in September pot them up. *Campanula pyramidalis* and *C. p. alba*, afford charming subjects for the decoration of conservatories and greenhouses if they are grown similarly to the preceding.

Primula obconica.—When the seedlings are of a suitable size, transplant them from the seed-pans into boxes at 1 inch apart, in a soil consisting of equal parts of loam and leaf-mould, with a liberal quantity of sharp sand added, place them in a warm greenhouse, and afford slight protection against bright sunshine. Later, cold-frame treatment is required.

Dracenas.—Plants which have been raised from stems and roots, may be potted into 60's, using a rather sandy, peaty soil, and be placed in a warm close frame with shading over them during the sunny parts of the day. Here the plants should remain till active growth ensues. Cuttings of *Dracenas* will strike at any season, also tops of leggy examples; and the nodules found at the roots of most of the species may be extracted and potted at any time. After potting, or any other root disturbance, water should be cautiously afforded for a fortnight or longer time according to the season of the year. The tropical *Dracenas* like a moist not too well ventilated house, and to be shaded from strong sunshine; fixed shading on the contrary is against the colours of the leaves being brought out perfectly. *Dracena (Alettris) fragrans*, *D. australis*, and *D. indivisa*, being natives of the warm temperate climes, succeed under ordinary greenhouse treatment. Although these are improved by stove treatment after being repotted or otherwise disturbed at the root. The genus is valued in gardens for the beauty of the foliage, and no effort should be spared to keep this free from thrips, red-spider, scale, and dust. If the water supply of the place is chalky or clouded, it should not be used for syringing these plants.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Pot Vines.—Those Vines which have ripe fruits upon them which is required to last in good condition for some time longer, must not be exposed to much heat, and should be afforded a considerable amount of top and bottom air in fine weather, closing the house in rainy or misty weather, and at such times affording a trifling artificial warmth. Ascertain by daily examination which plants require water at the root, never allowing the foliage to suffer from lack of moisture in the soil so long as the Grapes are hanging on the Vines. All surfaces should be moistened on fine days, in order to lay the dust. Pot Vines, when the bunches are cut, should be thrown away, as they are of no further use. In order to pack Grapes to travel long distances, the boxes used by Covent Garden Market growers are very suitable, these being made of light wood 18 inches by 12 inches, and 3½ inches deep inside measurement; in these the bunches are packed closely, and rarely get damaged if at the bottom a thin layer of wood-wool or Vine-leaves be placed, and over this a sheet of paper. The packer should begin at one end, laying in the bunches of Grapes one after another, until the box is quite full, laying a sheet of paper over all, and filling in all spaces with wood-wool.

Permanent Vines.—If the bunches are colouring, make moderate use of the heating apparatus by day and night, and afford ventilation freely when the days are favourable, also give a little air at night, except in very boisterous weather. The vinery at 6 A.M. should have a temperature from 65° to 70°, and as soon as the warmth rises 5°, ventilation at the top may, if the weather be fine, be increased; and again when 80° is reached, at which figure, or 85°, it may be kept. In the afternoon let the ventilation be decreased according as the temperature falls; at all times avoiding a sudden rise of temperature, which may cause moisture to condense on the berries. On dull days keep the hot-water pipes warm, and maintain a

temperature of 73° to 75°. As the colour in the berries increases, afford less moisture in the vinery until fully coloured, and do not damp down unless the temperature is up to the required figure by either sun or fire-heat. The swelling of the berries goes on with the colouring, consequently there must be no lack of water of the roots, and heavy applications of water will be necessary in well-drained borders, but less in heavy loams and deep ones till the crop is ripe. If the outside border was covered with tree leaves in the autumn it may now be almost stripped of these, leaving merely a few as a mulch. If the border is found to be lacking in moisture, afford a copious application of clear water; or if the border is known to be in need of manure, add one-half farmyard liquid-manure. On Vines carrying fruit, reduce the number of laterals; and if red-spider should appear, wipe the infested leaves with a sponge and soap-and-water. It is well not to apply sulphur to the hot-water pipes before the berries have stoned. Let all bunches be thinned when the berries are very small, thinning more severely those Grapes that will have to furnish the winter dessert, so that the berries do not touch each other when full grown.

The Latest Vinery.—Remove surplus shoots, stop laterals and leaders, and secure a sufficient number to cover the trellis. If red-spider appears before the Vines come into flower, use clean water and the syringe night and morning; and attend carefully to damping-down at frequent intervals.

THE APIARY.

By EXPERT.

Seasonable Hints.—Plenty of indoor work, which should not be neglected, will now be found to occupy the spare hours of the evening. As spring advances, time becomes more precious, and everything which can be got ready now will save time in the future—sections, supers, and frames may be fitted with foundation ready for use, and stowed away till wanted. Provide a few "frame-holders," i.e., rough boxes without top or bottom, made of half-inch stuff; they must be of the same dimensions as insides of the hives used, and are very useful for holding frames fitted with full sheets of foundation, or when extracting.

Query: Sending Swarms by Post.—1. In reference to swarms of bees being allowed now to go by parcel-post, do you think it will be a good way of sending them—for the welfare of the bees, I mean? It will be quicker than the ordinary passenger-train, but will the same care be taken of them as to ventilation and bumping about? If sent in a light box, a swarm would not exceed the limit weight of 11 lb. 2. If brood is "wired," is it necessary to have the top bar of the frame grooved or slotted with saw? What is the drawback to having a wooden comb-guide projecting three-sixteenths of an inch to which the foundation, after wiring, is made to stick by pressure? It has the advantage that the wax-moth cannot get at any wax projecting to the top-surface of frame under quilts, and looks a quick way of fixing. 3. Would four large syrup-bottles, arranged on a feeding-stage, with cheese-cloths over their mouths, the wooden panel they rest on being pierced with many holes, be as effective as an ordinary rapid feeder? It seems to me that by standing the stage I suggest direct on the frames, and packed warm over the bottles and round the stage, the bees would feed nicely. I would, of course, put on the usual quilts over feed-hole, but keep the quilts covered where stage rests, and have a thin board for the bees to walk on, as they would object to the quilts. This latter way would be easier to pack warm.

Reply.—1. We should never advise sending swarms of bees by post, nor do we think that any experienced practical man would think of doing so. Passenger-train is the proper conveyance for swarms. The real advantage, so far as bee-keepers, of the new postal arrangement is being able to send queens with a few bees by letter-post for a penny. 2. The proposed "wooden comb-guide" will no doubt answer the purpose, but inserting the top-edge of a sheet of foundation in the saw-kerf is so much safer when done, that we fear the wooden-guide will never find favour with those well up in bee management. The wax-moth has no terrors for bee-men who keep only strong colonies. 3. This is another point which only personal trial will decide. The four bottles can no doubt be made to answer the purpose, but, to our mind, not nearly so well as by using a rapid feeder of good type. With the latter, a stock can be made to take 10 or 12 lb. of food in a single night, while the fixing and filling is done in a very few minutes.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	MAY 7	Royal Botanic Society, General Meeting.
TUESDAY,	MAY 10	Royal Horticultural Society's Committee. Somersetshire Agricultural Society, Show at Weston (3 days).
FRIDAY,	MAY 13	Royal Botanic Society, Lecture.

SALES.

MONDAY,	MAY 9	Japanese Lilies, Palms, Herbaceous Plants, Palm-seeds, &c., at Protheroe & Morris' Rooms.
TUESDAY,	MAY 10	Imported and Established Orchids, at Protheroe & Morris' Rooms.
WEDNESDAY,	MAY 11	Palms and Palm Seeds, Orchids, Lilies, Border Plants, &c., at Stevens' Rooms.
FRIDAY,	MAY 13	Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—53°·4°.

ACTUAL TEMPERATURES:—

LONDON.—May 4 (6 P.M.): Max., 57°; Min., 49°.

PROVINCES.—May 4 (6 P.M.): Max., 56°, N. Foreland; Min., 49°, Aberdeen.

Mild, rainy, dull.

A RECENT number of the *Semaine Horticole* contained an article, by M. E. ROMAN, on raising cuttings, on the ill-success which sometimes attends this process, and the reasons for such failures. The writer says that fungus often appears in a propagating-house and ruins all the new cuttings. Often, again, woody, or semi-woody cuttings seem for some time to be flourishing, and indeed are so above ground; but beneath, are slowly "damping off," and at last have to be rejected. It is then said that the gardener has over-watered his cuttings and caused them to rot, while he himself is always ready to throw the blame on the fogs.

Really the fog has nothing to do with it, but it is fungous growth that does the mischief. Every living creature originates in a germ, which develops only if in a favourable situation. These germs influence all the evolutions of organic matter. Animal or vegetable substances if left to themselves decompose only under the influence of these bodies, known as microbes. Eliminate the microbes, and there would be neither corruption nor decomposition. One of these beings, the septic bacillus, attacks animal or vegetable tissues in their entirety, when their life is just ebbing, or when they are injured or torn—the bacillus attacks them, lives at their expense, and produces in them the phenomenon of putrefaction. When this bacillus has done its work, "saprophytes" intervene, and transform the products of corruption into nitrogenous matters, which alone can be assimilated by the roots of plants. At

present we have no concern with saprophytes, but will consider them later on.

Septic bacilli are widely diffused in Nature. In soils constantly enriched with decomposing matters, the septic bacillus is yearly multiplied and renewed. This is why cuttings of delicate plants do not succeed in garden earth.

This bacillus is found less abundantly in peat, as this soil is not mixed with manure.

The leaves and roots composing humus decompose very slowly, and it is probable that the saprophyte microbes, which are mortal enemies of the septic bacilli, have had time to destroy them. Therefore, peat is very advantageous for cuttings; but river-sand is even preferable, as if it contains the septic bacillus at all, it is only by accident.

Scientific experiments, then, show us that cuttings do better in sand than in peat, and in peat than in mould. But the septic bacillus is in the air as well as the soil, and especially in that of cities, where it is vitiated by organic matter of every sort. If the atmosphere were free from microbes, boiled milk, for instance, would keep sweet indefinitely, as boiling would destroy any microbes existing in it. PASTEUR found that in pure mountain-air such matters kept fresh, sometimes for months, with no trace of corruption.

Watering plants may also infect them, as the water almost always contains the bacillus of putrefaction, either from contact with contaminated air, or because it contains organic matter susceptible to decomposition. These considerations may explain why our cuttings fail. A cutting planted in an aseptic pan, in very pure air, and given water free from microbes, would perhaps never root, but certainly would not rot; and at the end of an indeterminate time would be found in exactly the same state as when planted. We must, then, do all we can to secure such conditions. The first idea is to introduce into the water aseptic substances to destroy the microbes to be found accidentally in the pot, and in the surrounding air. Unhappily, we know no substance that would do this without destroying the vegetable tissues with which it came into contact. It may exist, and we are led to think so by the statements made concerning the effects of Bordeaux Mixture, in which most powerful antiseptic, if it saturate the soil, Grape-growers tell us that their Vines grow and vegetate vigorously.

The best, or rather the only means of staying the decay of our cuttings, is to take aseptic branches and bring them into surroundings made as aseptic as possible. Nothing hitherto has been contrived or even advised in this direction. The following precautions should be taken, they are dictated by the discoveries of PASTEUR and his successors:—

1. Cuttings should be taken from healthy plants, with very clean knives, previously plunged in boiled water. They should be planted at once to prevent the contact of the cut and torn tissues with the air around.

2. They should be planted in a small quantity of river-sand, well washed. The sand should be heated, to destroy any microbes it may contain, by previously placing it in an oven at a temperature of about 200° C. It should afterwards be kept until required in hermetically-sealed boxes.

3. For watering, boiled water only should be used, which has been put, while still hot, into well-stoppered bottles. Water from boiler-pipes might be used, as this is frequently raised to a temperature of 100° on account of frost.

4. The atmosphere may be beyond our power, but we can take certain precautions to prevent it from transmitting noxious microbes to our cuttings. Propagating-houses, especially when old, are perfect nests of microbes. Not to speak of decaying vegetable matter, the soil is permeated with germs, for which also the damp edges of the lights form an excellent breeding place. The air of these houses should be frequently renewed, and the glass wiped and kept clean on the inside. Fumigation by evaporation of tobacco-juice should be frequent. Experience has proved that, with the exception of certain rare and delicate Lycopods, plants bear nicotine fumes without sustaining any injury.

5. Bell-glasses are useful to keep off the surrounding atmosphere, and so reduce the chances of infection. The deposit which gathers upon them should be frequently wiped off. It would be interesting to try the old form of bell-glass, which, instead of a solid handle at the top, had a tubular hole running through it. This aperture could be filled with cotton-wool, which would ensure the slow renewal of air without risk of drying up the cuttings; and as to the microbes contained in the air inside the glass, it is proved that a fairly thick layer of cotton-wool will keep them off. The bell-glasses should be removed for as short periods as possible, in order to wipe off the damp deposit, or to prevent too great humidity. These precautions may seem trivial, but they would soon become habitual, and ensure complete success with plants hitherto found delicate, and not easily multiplied by cuttings.

Kew.

It is high time that those who value the Royal Gardens, Kew, for the unrivalled opportunities they afford for scientific or artistic study should bestir themselves. Their privileges are threatened with extinction. The regulations for the admission of students were given in our last issue. It must be admitted that they are reasonable. Moreover, we do not think that any obstacle is placed in the way of anyone who has the least claim to early admission as a gardener or student. We believe also that the regulations are interpreted in a liberal and considerate spirit. Last year about 10,000 visits were paid by those having the privilege of entry, and in no case was the privilege abused. We can ourselves from personal experience of many years testify to the extreme importance and value of the morning hours in the garden to those engaged in research.

Now, if the proposals for earlier opening to the public be carried out, there is the greatest possible risk that these privileges will be withdrawn, or so curtailed as very materially to diminish their value. This is what we have to fear. These are the conditions we have to face. Why, we ask, should we, who are taxpayers as well as students, be subjected to this deprivation? Simply that the residents in the neighbourhood may send their children and their nurse-maids an hour or two earlier into the garden, where they are safe from trams and run-away horses. Visitors from London in the morning hours must necessarily be few, and for those who come on business, arrangement is made, as we have said. The claims of the student obviously very far outweigh the interests of the mere sight-seer or lounge; indeed, the latter are not to be mentioned in the same breath with the former. The primary use of Kew is as a scientific institution. If it can be

FIG. 107.—ROSE HYBRID POLYANTHA 'PSYCHE': COLOUR PALE PINK. (SEE P. 281.)

utilised also as a public lounge, well and good, always provided that the interests of the students and the interests of those responsible for the proper maintenance of the garden are not jeopardised. Parks and pleasure-grounds, greens and commons have we, particularly in the immediate vicinity of the Royal Gardens, but there is but one Kew.

Italian National
Chrysanthemum
Society.

ONE of the latest developments in connection with the popular autumn flower is, as we learn from Mr. C. HARMAN PAYNE, the formation of several new and important societies to promote its culture in various countries on the continent. The French National Chrysanthemum Society has well sustained its title. Last season the Amsterdam Chrysanthemum Club held its first show, publishing at that time a capital handbook for the use of visitors, containing the history and culture of the Chrysanthemum, lists of officers and exhibitors, and also the rules of the club. The movement has extended to Italy, and already the name of Mr. SCALARANDIS, gardener to his Majesty the KING OF ITALY, has become somewhat familiar even to English growers. From a circular recently to hand, we learn that a committee has been formed to carry out the necessary preliminaries for the formation of a society, having its head-quarters at Milan, to be called "La Società Nazionale Italiana di Chrisantemisti." Briefly stated, the objects are—1. To encourage and perfect the culture of the Chrysanthemum in every way possible. 2. To promote exhibitions in various cities in the kingdom of Italy by offering subsidies, Medals, Certificates, &c., for competition. 3. To publish a monthly or bi-monthly journal devoted to the flower in all its phases. 4. To organise conferences, &c., so as to diffuse and spread abroad the love of the flower in Italy.

The Society will be founded so soon as a sufficient number of applicants has been obtained. The circular is subscribed by such well-known names as MESSRS. BRISCOE-IRON-SIDE, A. SCALARANDIS, RADAELLI, and LONGHI & SONS. The provisional president is Mr. SCALARANDIS.

ROSE PSYCHE.—The hybrid Polyantha Rose Psyche is a seedling from the dwarf Polyantha Rose Golden Fairy, one of BENNETT'S introduction, crossed by Mr. G. L. PAUL with the pollen of TURNER'S Crimson Rambler. Its growth and habit, though more delicate, much resemble the Rambler. It is apparently quite hardy, and is very free flowering (fig. 107), but we fear not perpetual. The flowers are produced in clusters of from fifteen to twenty-five, and are 2 to 2½ inches across when fully expanded. In the bud stage they are very pretty, and well formed. The colour is white, suffused with salmon-rose and pink, with a yellow base to the petals. It is a real companion to Crimson Rambler. Plants in full bloom were shown at the Royal Horticultural Society's meeting, April 26, 1898, by MESSRS. PAUL & SON, Old Nursery, Cheshunt, when an Award of Merit was granted the variety.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, May 10, in the Drill Hall, James Street, Victoria Street, Westminster, from 1 to 5 P.M. At 8 o'clock the Rev. Professor G. HENSBLOW, M.A., V.M.H., will lecture on "Some of the Plants Exhibited." The Schedule of the "Show of British-grown Fruit," to be held at the Crystal Palace on September 29, 30, and October 1, is now ready, and can be obtained on application to the Secretary of the Royal Horticultural Society, 117, Victoria Street, S.W.

FRENCH NATIONAL CHRYSANTHEMUM SOCIETY.—At the conference held by this Society at Orleans last November, several papers on subjects relating to the Chrysanthemum were read by the members. A very full report of the proceedings was given in the Society's official publication, *Le Chrysanthème*, and the principal papers have now been reprinted in separate form, and form a brochure of thirty-six pages, with illustrations, and can be obtained from the publisher, M. OCTAVE DOIN, of Paris. These papers bear the titles of "Chrysanthemum Maladies and Parasites," by Mr. CHIFFLOT; "The Fertilisation of the Chrysanthemum," by M. GERARD; "The best Manures and Composts to Use in Chrysanthemum Culture," by Mr. H. FATZER.

CHRYSANTHEMUM SHOW AND CONFERENCE AT LILLE.—The Northern French Chrysanthemum Society will hold a Show and Conference at Lille on November 10 next. The Palais Rameau, a building well suited for the occasion, has been secured, and the co-operation of nurserymen and amateurs in France and abroad is solicited to make the event worthy of the Society. Visits to neighbouring horticultural establishments are to be arranged, and the schedule, now in course of preparation, will shortly be issued.

NATIONAL HORTICULTURAL SOCIETY OF FRANCE.—The Council of the Society has determined to organise a concert, followed by a ball, on Saturday, May 21, during the period of the Exhibition. The proceeds will be given to the fund established for the benefit of distressed gardeners.

AUSTRALIAN FRUIT.—The officials of the Peninsular and Oriental Steamship Company send us the following:—"We have received telegraphic advices from Melbourne of date April 28, of the following shipments of fruit, viz., by the *Ophir*, of the Orient Company, 22,000 boxes; by *Arcadia*, P. & O. Company, 9,700 boxes of fruit. The *Arcadia* is due about June 5. According to original arrangement, the *Ophir* is due on the 30th inst.

FLORA OF TROPICAL AFRICA.—We are glad to be able to announce the publication of another part of this very useful work. It will be remembered that from various circumstances the issue of this work was suspended for several years. It has recently been resumed, a recommencement being made with the Monocotyledons. These being completed, the orders intervening between them and those already monographed will be dealt with in due course. The present part, like the one immediately preceding, is mainly taken up with the Orchideæ. Mr. ROLFE has here given us a complete monograph of tropical African Orchids. Some idea of the importance of this monograph may be obtained from numbers of species of certain genera; thus, of *Bolbophyllum*, there are 41 species, of *Megacalinium* 20, of *Eulophia* 65, of *Lissochilus* 83, of *Polystachya* 74, of *Angræcum* 48, of *Listrostachys* 52, of *Habenaria* 107, of *Satyrion* 33. *Disa*, a genus monographed by Mr. N. E. BROWN, counts 20 species within the limits of this flora. These figures may give some impression of the Orchid flora of the region as well as of the labour involved in comparing and describing so large a number of plants. The Scitamineæ, including the Zingiberæ, Marantæ, Cannæ, and Musæ, are dealt with by Mr. BAKER, by whom also the Iridaceæ and the Amaryllidaceæ are monographed. We are by no means disinterested when we offer our congratulations to the Director of the Royal Gardens and his staff on the valuable addition they have made to the knowledge of African botany.

AN IMPROVED GARDEN-HOSE.—The trouble experienced by many gardeners with garden-hose bursting, kinking, or rotting is met by another important improvement in this article by the firm of MURRY-WEATHER & SON, 63, Long Acre. This firm has been successful for years past in manufacturing durable garden-hoses, which shall last more than a season or two in regular work. The latest method of securing durability for their hose consists of an external coating of fine quality rubber of substantial thickness, which effectually prevents the canvas plies being soaked with

water, as in ordinary hoses, and prevents rotting, which soon means the destruction of the hose. The ends of each length are also hermetically sealed with rubber to protect the canvas from water. To give flexibility, this has an internal coating of the best and most pliable rubber, and thus kinking and consequent stoppage of the flow of water, causing bursts in the hose, is prevented.

STEREUM HIRSUTUM.—Professor MARSHALL WARD gives, in the *Philosophical Transactions*, B, 1898, p. 123, an account of the artificial cultivation of this fungus from the spore to the development of the fructification, and of the manner in which the fungus attacks the wood of trees.

UNIVERSITY EXTENSION COLLEGE, READING.—The fourth annual report of field experiments carried out under the direction of Mr. DOUGLAS GILCHRIST in various localities, is a very interesting and instructive document. In addition to the reports of the experiments, of which a useful summary is given, there are suggestions for the appropriate manuring of certain crops, notes on various manures, their nature and use, the composition of foods, &c. A great deal of accurate and practical information is here given in a small compass, so that the document is well worth preserving for reference.

POLITICAL FLORAL DEVICE.—The *Weekly Florists' Review* (Chicago and New York) for April 7 describes and illustrates a political device carried out by a Cleveland florist, which will interest admirers of this style of decoration. A portrait of General MACEO was framed in green Galax leaves with crossed sabres at the top, crossed scabbards at the bottom, and American flags for background. In another corner was a large plaque of green Galax leaves bearing the Cuban flag traced out in white and red Carnations and blue Hyacinths. Carnations and Roses in vases supplied centre ornaments, and all were backed and framed with grey moss.

POTATOS.—Elaborate experiments on the manuring of this crop have been made, in conjunction with Mr. ARTHUR W. SUTTON, in MESSRS. SUTTON & SONS' trial grounds at Reading, and at five other centres, a report of which is given in the fourth annual Report of Field Experiments made under the direction of Mr. DOUGLAS GILCHRIST, on behalf of the University Extension College, Reading. These all tend to show that Potatoes do best on land enriched with the manuring of previous crops; that on such enriched land the direct application of many artificial manures to the Potato crop may do harm, especially where there is a comparatively dry soil and climate: that on soil in rather poor condition the crop of Potatoes can be much increased by the judicious application of artificial manures. Potatoes do best on a rich, free, sandy loam, which contains a fair amount of vegetable matter, and are most successfully grown on soils which are in good condition. As a rule, potash manures increase the crop, although in certain instances the result may be otherwise. A useful dressing per acre for this crop has been found to be: Twelve tons farmyard-manure, 1½ cwt. nitrate of soda, 3 cwt. superphosphate, and 1 cwt. muriate of potash. It is preferable to apply the muriate of potash in the previous autumn; the superphosphate may be applied at the same time, or at the time of planting, and the nitrate of soda as two top-dressings in the early stages of growth. Early Potatoes receive more liberal treatment, and a larger amount of nitrogenous manures is generally applied.

FINGER-AND-TOE DISEASE ON SWEDES AND TURNIPS.—The results of experiments to find the best check for this disease, made at Headington, mentioned in the *Fourth Annual Report on Field Experiments*, carried out under the direction of the University Extension College, Reading, are of great interest. These show that this disease is most prevalent when the soil is deficient in lime, and that any form of lime—hot lime, chalk, or gas-lime, thoroughly mixed with the surface-soil—will do much to check the disease. Apparently, however, the lime must be applied to the soil a considerable time before the Swedes or Turnips are grown. Basic slag has to a small extent only checked the disease. On a farm

where this disease is prevalent an effective method of dealing with it would be to apply all farmyard manure produced from affected roots to those parts of the farm where Swedes and Turnips are not grown; to entirely stop growing Swedes or Turnips on the infected areas of the farm for a number of years; and to gradually give all these infected areas a careful dressing of some sort of lime. Swedes or Turnips should not be grown on these areas till about two years after the lime has been applied.

"THE ILLUSTRATED BOUQUET."—Comparatively few gardeners will remember the serial bearing the above title, and published by the now long-defunct firm, E. G. HENDERSON & SON, of St. John's Wood. It is a very showy publication, which appeared at intervals between 1857 and 1864, and the only fault one can find with it is that some of the subjects were a little overdone—a fault not unknown among other trade publications. It consists of three thin folio volumes, containing in all eighty-five beautifully-coloured plates, mostly representing two or more subjects. The first volume is dedicated to the Princess Mary of Cambridge. The work is apparently rare, or at least it is seldom in the catalogues, and not a single copy is offered in Quaritch's colossal catalogue of nearly 2400 pages. It is a fragment of the history of gardening and garden-plants of forty years ago, and recalls some pleasant memories of the past. The first plates represents the yellow Tea Rose Isabella Gray, and the second a group of eight varieties of Verbena. Next come hybrid Bouvardias, zonal Pelargoniums, Gloxinias, show Pelargoniums, Begonia Rex, Fuchsias, Achimenes, pompon Dahlias, Eucharis amazonica, Calceolarias, pompon Chrysanthemums, Clanthus Dampieri, Gazania splendens, Dianthus laciniatus, and a host of other showy plants, coloured in the very best style. The artists were Mrs. Withers, Miss Sowerby, and James Andrews, all three clever and painstaking flower-painters. Kew has recently purchased a very fine copy of this handsome work. *W. B. H.*

MARKET GARDENERS' NURSERYMEN'S AND FARMERS' ASSOCIATION.—The subjoined letter tells its own tale. We trust that many others will follow the example of Mr. HOLLIS, and thus put an end to the uncertainty of the law relating to rating. It is evidently a matter of supreme importance to growers, and it now rests with them whether or not they will do their best to maintain their position or not:—

"I am glad your Association think of appealing to the House of Lords on the Rating case, and I shall be willing to subscribe 7 guineas, which is the amount I shall save on half-year's rate if the case is won. If other growers subscribe on same basis, the £1000 wanted will easily be got.
 "(Signed), H. W. HOLLIS, *Fruit-grower, Worthing.*"

DESTRUCTION OF A SEED AND BULB WAREHOUSE.—The extensive premises of Messrs. WATKINS & SIMPSON, situated in Exeter Street, Covent Garden, were almost consumed in a fire which broke out on Thursday, April 28, in the early hours of the morning. The whole of the four stories of a building used as stores, offices, &c., were gutted, and the roof was destroyed. The fire threatened at one time to involve the entire block of buildings between Exeter Street and Tavistock Street. Messrs. WATKINS & SIMPSON have located their offices and warehouses *pro tem.* at Mercer Avenue, Neal Street, Long Acre.

HORTICULTURAL COLLEGE, SWANLEY.—The first of a series of four lectures on some popular florist's flowers, was delivered before a large body of students of both sexes in the Lecture Hall of the College on Monday afternoon last. The lecture briefly touched on the Anemone, Anterrium, Calceolaria, Cineraria, &c., reserving the Auricula, Dahlia, and Florist's Tulip for more extended notice. These subjects were illustrated by flowers and coloured diagrams, and a great deal of interest was manifested by the students. A second lecture will be delivered on Monday next.

HORTICULTURAL CLUB.—The next meeting, to be held on Tuesday next at the Hotel Windsor, will derive additional significance from the circumstance that the Rev. H. H. D'OMBRAIN, the founder, and for

so many years the diligent and sympathetic Secretary, attains his 80th birthday. It is hoped that a large gathering will take place, to express the kindly feeling and gratitude which all the members must feel towards this much-respected member of the horticultural body. Arrangements are being made to celebrate the occasion.

PUBLICATIONS RECEIVED.—*Pharmaceutical Journal*, April 23.—*The Culture of Vegetables for Prizes, Pleasure, and Profit*, E. Kemp Toogood, Southampton. — *The [Tokyo] Botanical Magazine*, February 20, contains "Notes on some Liu-Kiu Plants," by Professor J. Matsumura; "List of Plants collected in Mount Togakushi and its vicinities," T. Inui, H. Hatton, and S. Kusano; "Plantæ Japonenses novæ vel minus cognitæ," T. Makino, and various articles in Japanese, one of which treats of "Plants employed in Medicine in the Japanese Pharmacopœia."—*Canadian Horticulturist* (Toronto, Ontario), April. This includes articles on, "The Pæony," "Outdoor Flowers in February in British Columbia," "Trees and Shrubs in Niagara Falls Park," "Iroquois Horticultural Society" (with portraits), "Preparing new Strawberry Beds," &c.—*Cape of Good Hope Report of the Government Botanist and Curator for 1897*; a satisfactory record of progress.—*Agricultural Gazette of New South Wales*, vol. ix., part 2, includes papers on "The Making and Improvement of Wheats for Australian conditions," "Fruits at the Richmond River Experiment Farm," and various articles relating to stock-farming.—*The Tropical Agriculturist* (Colombo), April. This number treats of "Pioneers of the Planting Enterprise in Ceylon (C. T. and Frederick J. Haddon)," "Coffee in Brazil," "Indian Tea Crop," "Coffee Planting in Ceylon," "Rubber Cultivation," "Coffee in Hawaii," and many similar subjects.—*Indian Gardening* (Calcutta), a weekly journal "devoted to gardening, agriculture, and the allied sciences."—*Investigations on the Native Vegetation of Alkali Lands*, by J. Burt Davy.—From the Agricultural Experiment Station, University of California:—*Investigations in the Bark of Trees*, Prof. Th. Meehan, being Bulletin No. 29 of the Department of Agriculture, Pennsylvania. Not the least interesting portion of this paper are the clear illustrations scattered through the text. *The Plants of Lewis and Clark's Expedition across the Continent*, 1804-6, Th. Meehan, reprinted from the Proceedings of the Academy of Natural Sciences of Philadelphia.—*The Florists' Review*, Chicago and New York.

GARDEN GOSSIP.

ROYAL HORTICULTURAL SOCIETY'S GARDENS.—This is a year of fruit-blossom. In every garden and orchard we have visited, hardy fruit-blossom is uncommonly abundant. Never does a fruit-garden look prettier, or more full of possibilities than now, with its Apple, Pear, Cherry, and Plum-trees wreathed in white or pink. Yet, whilst admiring the display, we talk of possible contingencies, and hope that nothing will happen that shall cause us to say in September, that 1898 is a year of fruit-blossom only. At present there is nothing to make the fruit-grower take a despondent view of the future, but how full are the next few weeks of anxiety nevertheless.

At Chiswick, the superintendent, Mr. S. T. Wright, is busy with the miscellaneous work inseparable from spring, and the Gardens at the commencement of the season offer unmistakeable proof that they are well managed. Indoors and out, cleanliness and neatness are apparent, and every particle of space is now, or will soon be, planted with a crop. The trials of Violas, Annuals, Strawberries, Peas, Onions, and Tomatos, have been arranged for, and the sowing and planting completed.

With regard to the annuals, it may appear to some (ourselves included), that their importance is hardly sufficient to justify a trial of varieties in such an experimental garden as we would regard Chiswick. The majority of the trials, nevertheless, are most useful, and the results in the case of Strawberries, Peas, Potatos, &c., form a guide to the committees in granting awards to novelties. Some of the fruit-

quarters have been made much better and more convenient by replanting during the last few years, and the collections afford a visitor the opportunity to observe the characteristics of all the most valuable varieties.

Peaches and Apricots upon the walls will not be abundant; the Peaches especially are sure to be thin, the blooms having fallen. Plums, as standard or bush trees, have lost a considerable proportion of the bloom, but sufficient remains at present to produce a good crop. Indoors the Vines look well, and have broken strongly, there being every indication of a full crop of Grapes. Peaches are not so good; the flowers were open during a fog, and many have failed. The house of pot-Figs looks well. The trees were shaken out and repotted in the winter, and have consequently carried a thin first crop, but the summer crop will be an abundant one. The shaking-out of the variety Pingo de Mel did not cause the tree to cast a fruit; and it may be recommended as one of the very best new Figs for forcing. In one of the plant-houses there are numerous varieties of zonal Pelargoniums, for there is to be a trial of these also. Several of the propagation-pits have been re-roofed and otherways overhauled by the garden staff, and these necessary repairs have effected much improvement in the general appearance of the structures. The well-known Camellia-bushes in the open border have still a few blooms upon them. Altogether, the gardens are well managed, and much credit is due to Mr. Wright and his staff. *P.*

—The superintendent, Mr. S. T. Wright, seems to have arranged for some useful work to be performed by the Floral and Fruit Committee during the ensuing season. A remarkable trial of comparatively hardy annuals sown in beds, each some 6 feet square, on a long border, can hardly fail to be at once interesting and attractive. The border is several hundred feet in length. On the opposite side of the footpath fronting this border is one of narrower breadth, and this is filled from end to end, and is carried on into a supplementary border with Violas, of which there are about 300 half-dozens, though, of course, some are of the same varieties, but from diverse sources. This will constitute the most complete and interesting trial of these popular hardy flowers yet held at Chiswick, or, indeed, almost anywhere. Zonal Pelargoniums in pots, and planted out; Cannas, hardy Phloxes, Pæonies, and other things, bid fair to furnish abundant work for the florists. In the vegetable department there is a trial of some sixty varieties of Potatos, some half hundred of which are reputedly new. Then there is a big trial of Peas, just a few of which are standard varieties, but the remainder also are classed as new. Onions, again, of which there were seventy-six stocks sown, will attract great attention. In all cases those sown in the autumn will enable a fair trial to be made of fitness for that purpose, in spite of the mischief wrought amongst all the varieties by the winter fogs. There is also a trial of Lettuces, and in a long pit one of early Radishes, of which a large collection may be exhibited at the Drill Hall on the 10th inst. In fruit, Strawberries of old and young plants should furnish capital trials. Frost has not dealt tenderly with the abundant bloom on stone-fruits and Pears, but the luxuriant bloom on the Apple-trees should be productive of a grand crop of these excellent fruits. *A. D.*

GUNNERSBURY PARK.

We found Mr. Reynolds very busy thinning a few of his choicest bunches of Grapes. He had something grand to show us in the shape of a magnificent display of Vanda teres in flower. Many of our readers have probably seen the Gunnersbury Vandas in bloom; those who have not, have so far, missed a great treat. Seventy-two spikes of bloom had been removed before we saw them, but one would scarcely have known it, so fine was the display. There were still upwards of two hundred spikes, and some of them had seven blooms upon each. The plants are in long, rather deep, wooden-boxes, containing nothing but sphagnum-moss and crocks. Of course,

the greater number of roots are above the moss, and they, no doubt, absorb moisture, and probably gases from the atmosphere. It is worth remark, that in the house where this *Vanda* succeeds so well, there is a large bed of leaves and tan, in which the collection of *Ixoras* is plunged; and such a body of partially-decayed leaves, which are constantly moist, must have a decided effect upon the air in the house. Water is afforded so soon as the flower-spikes are growing freely, and continued until at the end of the summer, the plants show signs of lessened growth, when they are induced to rest by reducing the supply. This is generally in September, but the time varies according to the season, whether it be an early or late one. As soon as growth is completed, it is desirable to get the plants thoroughly ripened, and here it is we suspect that many growers fail to obtain flowers. It should be remembered that so long as water is given in usual quantity, and there is sufficient heat, growth will proceed, even if slowly, and then there is insufficient autumn sun to ripen it. There were several other species of Orchids in flower, and a fine lot of decorative foliage plants in other houses. Gunnersbury Park has long been a noted place for fruit, and a walk through the vineries, Peach-houses, Figery and orchard-houses is very enjoyable. The Vines in various stages promise well, as do most of the Peach-trees, and in the Fig-house were plenty of ripe Figs. A vast number of Strawberries are forced, and Mr. Reynolds still prefers *La Grosse Sucrée* for early forcing, say until the beginning of April. At this date he agrees that *Royal Sovereign* is the better one. There is a glorious show of bloom upon the Cherry-trees indoors, and upon Plums. At this garden and that in Mr. Hudson's charge at Gunnersbury House, one sees more attention given to *Pelargoniums*, scented-leaved and others, than is now common. Mr. Reynolds is training large specimens in various shapes of zonal varieties for positions on the Terrace and in Messrs. Rothschild's garden in Piccadilly. A fine new span-roofed house has lately been built for the cultivation of *Pelargoniums*. The hardy fruit blossom is abundant here, as elsewhere. *P.*

THE FRENCH ASPARAGUS INDUSTRY.

MR. EDWARD CONNER'S life-like description of this in general, and of *Asparagus*-culture at Argenteuil in particular, in a recent *Gardeners' Chronicle*, vividly recalls a visit to the same district under the guidance of a late president of the Board of Trade some twenty-five years ago. The system so graphically described by your correspondent was then in full force, and here seems to have been little change, unless in enlarging the area under culture, and feeding the crops with more and richer manures. It makes a Britisher's mouth water to read that the supply from the suburbs of Paris, of which Argenteuil is the centre, is some 10,000 tons in the season, and that the total consumption of Paris amounts to 13,000 tons a year, or about thirteen pounds per head of the population. And yet no one who has lived in any of the main streets near the Halles Centrales through the *Asparagus* season, and seen the piles of *Asparagus* come and go, and almost wholly load up the coster's barrows from the middle of April to the middle of June, will think the estimate of consumption exaggerated. Within the last half century the *Asparagus* trade of Argenteuil has risen from an annual value of 30,000 francs to one of 2,000,000 francs, which is still increasing in various directions by leaps and bounds. Just as Endive, Chicory, Lettuces, are the national salad, so *Asparagus* and Mushrooms are the national vegetables. They are eaten hot and eaten cold, with oil, vinegar, cream, butter; and everybody, the poor as well as the rich, seem to eat them.

The fact being, there is a fashion in the use of vegetables as in the shape of dresses and of bonnets. In France it runs on *Asparagus*; here, and now, it is red-hot haste after Tomato, &c. And there is no denying that this fashion and hunger for *Asparagus* in France has done very much indeed to lay the foundation of the *Asparagus* industry on its present

basis, so broad and wide, as well as force it into broader areas in the future.

Political economists never weary of telling us that it is a risky proceeding to allow supplies to outrun demands to any great extent. As the surplus, if any, of *Asparagus* could be tinned, the risk in this case of loss would be very slight.

Were a combined and vigorous effort made by growers to float good home-grown *Asparagus*, at reasonable prices, on our market, the probabilities are that it would be even more successful. Do what we will with the Tomato, it is still a tender plant; while the *Asparagus* is a perfectly hardy perennial, a native of Britain, and found wild in Russia, and in various countries of Europe and Asia. In fact, the wider our experience in the examination or culture of garden *Asparagus* the more certain it seems that there is but one variety. Country, site, soil, culture, situation, injurious feeding are chiefly responsible for the numerous names, as Dutch, French, Argenteuil, American, English, Scotch, Grayson's Giant, Conner's Colossal, Palmetto, Thetway's New Emperor, Battersea, Deptford, Reading, Mortlake, Ely, Colchester. All the so-called varieties of the common *Asparagus* are also alike hardy in our climate. Young shoots prematurely early are often cut down by frost. But the crowns and roots, unless coddled with tenderness by excessive coverings of earth or manure, are perfectly hardy. It is very important to bear this in mind, on the score of what will probably prove a great expansion of *Asparagus* culture in Britain.

I was much struck with the subordinate place given by Mr. Scarlet, of Musselborough, to home-grown *Asparagus* in his able lecture recently before the Scottish Horticultural Association on the supply of the Edinburgh and Glasgow markets with fresh vegetables; home-grown *Asparagus* was hardly in it. This need not have been so. The most catholic cosmopolitanism hardly expects us to refrain from developing our own resources to oblige or enrich the French or other foreign growers of *Asparagus*. Our climate is equal to theirs, if not superior, for the purpose; and we have wood-ashes, night-soil, salt, sewage, pigeon, fowl, and other manures *ad libitum*, with the command of the markets of the world for Peruvian and other guanos, and all the best artificial manures.

Labour is cheaper, and hence more plentiful in France and on the Continent generally; growers are also more generally the owners of the ground they cultivate, and think no labour or effort too great to command the finest "grass." Through their careful grading into three sizes, the French growers get more for the best than we Britishers would get for the whole bulk sold in a rough mixed lot; indeed, Mr. Conner says the bundles range from 11½ francs to 7 francs each.

The skill of the French and other foreign growers may be said to be hereditary. The industry has been handed down from father to son, and each grower is an expert as well as an enthusiast. The mustering at 4 A.M., the cutting of the grass before the dew is dried off it by the morning sun, the night journey to Paris, the early sales in the Halles Centrales, the careful and laborious manifestation with which they cut or twist off the edible stalks, excite our admiration, and merit our praise.

It is, however, extremely doubtful whether it would prove either prudent or profitable to copy the Argenteuil culture too closely in this country. In so far as the means employed to secure such a rich, friable, mellow soil, as one finds in this suburb of Paris, it must foster the culture of the "grass" to the uttermost. But where it comes to earthing-up of the crowns from 8 inches to a foot deep to blanch the stems, one is compelled to ask—Where's the benefit? Nothing impressed me more at Argenteuil than the laborious nature of the uncovering or re-covering by a bad or a small fork of the crowns at each cutting. Your correspondent seems to have been quite fascinated and converted at sight on the spot. I was not. Mr. Conner says the earthing up is to force the stems to become blanched, and arrive just at the surface white and tender. And then he adds—"If allowed to come through the earth, the

ends will become green, and be harder, and less delicate." The first part of both these sentences is a mere truism; and the second portion of both cannot be said to have been proven. Assuredly, whiteness and tenderness do not run in couples in the larger portion of French *Asparagus*; and they seldom give any but mere wiry sprays, the chance of proving whether or not if good fat "grass" becomes green it shall become the harder or less delicate in consequence of its greenness is not given. On the other hand, the whole of British experience proves the contrary. Blanching mostly renders vegetable tissue more crisp and sweet, viz., Celery. But the same process renders *Asparagus* shoots hard and tough—hence, their only edible morsel is the mere tip, and the remaining 6 or 7 inches of blanched stems is hard and harsh. Only the supremacy of fashion at our tables could have tolerated such wilful waste at such great cost for so many years. By ignoring the earthing-up and the blanching, the British will greatly reduce the cost, and place green-grass on the market from 6 or more inches long, crisp, sweet, tender, all the way from base to crown of equal size and superior quality to the best foreign grass. Argenteuil is a good object-lesson book even for the best home-growers, of whom we have many among us, but let us steer clear of the waste of mounting an edible morsel on a stout blanched stick some 8 inches long, and almost as thick as a lady's wrist, instead of allowing the latter to grow into a tender crisp green stems from 4 to 8 inches long, furnishing half of a good dinner for a hungry man. *D. T. F.*

ALPINE GARDEN.

NEW AND RARE PLANTS FOR ROCKERIES.

(Continued from p. 170.)

Erodium chrysanthum, L'Hérit, is one of the rarest and most interesting of rock plants from the East, as its flowers are a very good yellow colour. The plant is similar to a dwarf *E. olympicum*, with a thick rhizome, and forming large tufts of greyish foliage; the flowers are large yellow, and cover the plant from August to October, as says Mr. Boissier, who imported the plant into his garden from Valleyres more than fifty years ago. It grows in the crevices of rocks in the alpine regions of Greece, on Taygetos and Parnassus. The cultivation of it is not difficult; put it in a crevice of the rocks in a very sunny and dry place, as the root easily rots, and let it alone. Mr. Leichtlin, in his beautiful garden at Baden-Baden, cultivates it very easily.

Eryngium glaciale, Boiss., found by the writer between the sterile rocks forming the summit of the Sierra Nevada, Spain, between 8000 and 10,000 feet, is a dwarf plant not exceeding 10 centimetres in height, and which may be considered as the South Spanish form of *Eryngium Bourgati*. The bracts are spinose, and of a light blue colour in the time of flowering. This plant is rare in rock gardens, and must be cultivated in a sunny and dry place. It seeds freely, and is easy to propagate by sowing.

Erysimum thyrsoideum, Boiss., from the alpine regions of the Taurus and other mountains in Armenia and the East, is a very distinct plant with silky and silvery foliage, and Wallflower-like blossoms. It likes sunshine, and the crevices of rocks.

Falcaria scioides, Ascherson, is a pretty eastern Umbellifer, with serrate and ornamental leaves and small heads or umbels of white flowers. It succeeds anywhere in a good soil, and is seldom seen in gardens.

Ferula Asafetida, L., and *Ferula Nanthex*, Boiss., are two official and much valued plants, growing between the stones and rocky places of the mountains in the East (Turkestan, Afghanistan, Baltistan, &c.). They have large thick stems, little whitish flowers in umbels, and deeply cut leaves. They are rare in gardens, although of easy cultivation and good habit. They must be, as we have proved here, kept very dry throughout the winter and resting season, like other plants from Turkestan.

Galium tyrolense, Willd., is a dwarf form of the *G. erectum*, Huds., creeping over the rocks, and very good for partly shady positions.

Gentia horrida, D.C., is an irregular little shrub, forming dense ash-coloured tufts, never higher than 25 centimètres, which are, in July, covered with light yellow flowers in small capitules. The plant is rare, and one of the best of all the rock-shrubs; it grows only on a little hill in the west of France, and in the eastern Pyrenees. But it is, à proprement parler, a Spanish plant. It grows well between the rocks in a sunny place, and needs a deep soil as the roots are very long. We increase it by cuttings made in August under a cold frame or a bell-glass, and in sand. Among Gentians we find many beautiful kinds which are seldom seen in rock-gardens. *Gentiana angustifolia*, Villars (non Michx.), is by far the best of the acaulis group. Its stoloniferous stem, its very bright green and shining narrow leaves very lightly veined, and its large deep-blue flowers, well marked at the throat with five green spots, are very distinct. The plant likes a chalk soil, and is the best of the limestone-loving Gentians. It is of easy cultivation, and needs only sunshine and a good rich soil. It grows in the limestone-Alps of Savoie.

Gentiana Favratii is a good hybrid between *G. verna* and *bavarica*, which is common in the neighbourhood of the Dent de Mordes in the Alps of Canton de Vaud. The leaf is thick, and in form is just between the round leaf of *bavarica* and the acute one of *verna*; the flowers are of a very fine blue tint, and resemble those of *bavarica*. This species is not yet in general cultivation, but will be, I think, very popular when known.

Gentiana pyrenaica, L., is a dwarf and pretty plant, growing between the rocks in the pasturages of the Pyrenees. It forms small tufts of narrow and shiny leaves, from which rises the stems, not higher than 5 centimètres, bearing sky-blue flowers, resembling those of *G. verna* but smaller. It likes a small and well-drained niche in the rockery, and full sunshine.

G. Rostani, Reuter, is identified in the *Index Kewensis*, with *G. bavarica*, but is quite a different plant, and easily to be distinguished from it. Its leaves are much larger, of a dark-green colour (light and shiny in *bavarica*), not shiny and acute; the stems are long, often 20 centimètres (never higher than 10 c. in *bavarica*), and the calyx long and slender; the flower is like that of *verna*, but the tube of the corolla is larger, and the deep blue of the petals is also characteristic. The plant grows in the turfy alpine pasturage of the Valdese valleys in Piedmont, and on Mont Viso. It is a very nice plant for the rockery, where it must be planted in a moderately sunny place, and in turfy, well-drained ground.

Geranium Traversii, Hook., from the mountains of New Zealand, where it grows in the grass and between the rocks of the alpine region, is a very useful plant for the rockery. The leaves are silvery white, just as are those of *G. argenteum*, but much larger; flowers large, well-opened, of a light purple colour, streaked with carmine. It forms a big bush, and flowers throughout the whole summer. M. Cockayne, who sent me the seeds from New Zealand, tells me it is one of the most conspicuous flowers of the country. It is a hardy plant, but in the north it would be wise to cover it in the winter.

G. sessiliflorum, from the same districts, has handsome foliage but small flowers, forming in the centre of the tuft, which is very dwarf, a little cushion of white blooms.

Geum speciosum, Alboff (in *Bulletin de l'Herbier Boissier*, 1893, p. 244), a very singular and characteristic plant with large leaves, of the form of those of *G. montanum*, but larger; flowers large, very showy, of a bright, yellow-orange colour, rather resembling in some specimens those of *G. coccineum*. It is a good plant for rockeries and gardens; it grows freely in any light and good soil, and likes sunshine.

Globularia cordifolia alba.—The type is often cultivated in gardens, and is considered as one of the best

of rock plants; the white-flowered form is a beautiful one, and effective on rockeries.

Heracleum Mantegaffianum, Levier and Gommier (in *Nuovo Giornale Botanico Italiano*, vol. ii., No. 2, Avrol, 1895, p. 79), is the largest *Heracleum* known. The writers found it on August 16, 1892, near the River Kliutsch, in Abchasia, where it was growing with *Tommasinia* and other large plants. The size of the Giant Parsnip impressed the two botanists, and, as the plant was out of flower, they took seeds of it and brought them to me. Two years after we could have sent them leaves and flowers of the most gigantic perennial we ever had in our garden, as the stem was 2½ mètres high, and the diameter of the tuft was 4 mètres. The umbel of flowers was 1½ mètre in diameter, and Messrs. Levier and Gommier counted 10,000 flowers on it. These flowers are yellowish, and like those of all other *Heracleums*, but the strong aromatic odour of the plant is characteristic. *Heracleum Mantegaffianum* is easily cultivated, and grows large in proportion as the soil is deep and good. It is a very ornamental plant, and useful for shrubberies, wild gardens, and alpine gardens.

Iberis Bernandiana, Gren. et Godr., from the highest parts of the Pyrenees, where it grows between the rocks. It is a dwarf plant, forming dense tufts of deep green foliage, quite covered in June and July with fragrant lilac-coloured flowers. In the rock-garden it requires sunshine, and a deep, well-drained soil.

Iberis Gartonii, Delacroix, from the lower regions of the Pyrenees, is a dwarf form of *Iberis semper-virens*.

Lepidium flexicaule, Kirk, from the mountains of New Zealand, is a small dwarf plant, which rapidly covers the rocks between which it is planted, and has very ornamental foliage.

Linaria æquitribola, Spreng., and *L. hepaticifolia*, Stand., are two dwarf and creeping varieties of Toad-flax, which grow between the rocks and walls of Corsica and Sardinia, and are nearly allied. They may be considered as Liliputian forms of the Ivy-leaved Toadflax, and they are so spreading that when once established on a wall they rapidly cover it. They are not taller than the well-known *Arenaria balearica*, and are covered with purple flowers from May till December. They require sunshine, and a warm situation. *H. Correvon*, *Alpine Garden, Geneva*.

SEEDLING NARCISSI.

THE following is an abstract of an address given by the Rev. G. H. Engleheart, at the meeting of the Horticultural Club on April 12 last.

Disclaiming any intention of touching upon the more general subjects of the geographical distribution, the horticultural history, or the cultivation of the Narcissus, Mr. Engleheart prefaced his remarks by the reflection that gardeners who may be said to be in "deadly earnest" may be roughly divided into three classes—the collecting or acquisitive gardener, whose main object is to own more and better plants than anyone else—not, perhaps, the worthiest type, yet not without much usefulness, especially to those who have plants to sell. Secondly, there is the grower—the man who would fain bloom some plant which no one has bloomed hitherto; who would conquer *Nepenthes Rajah*, or some intractable alpine. Thirdly, there is the raiser—the man who concentrates his gardening energies upon the improving of some plant by hybridisation and seed-selection. And of all gardening work, undoubtedly this is the most fascinating. To this work belongs the sense of a certain creative power, and the peculiar satisfaction which comes with the attainment of a definite end proposed, especially when it is reached, as in this particular case of the Narcissus, after years of waiting. The raiser will never again care for mere acquisition or cultivation.

The raising in England of Narcissi from seed has its points of distinct interest. For the amateur worker there is the consideration that the Narcissus is *par excellence* the amateur's flower. With scarcely half-a-dozen noteworthy exceptions the whole of our

host of garden Narcissi have been raised by amateurs. And it is a peculiarly English flower. Englishmen have made it what it is: it is the English *Amaryllid*, suited to our climate, and occupying our markets and our private gardens at a season when the appetite for flowers is keen and unglutted by the satiety of summer. But the main reason why there is satisfying and endless interest in the raising of this flower is this, that the possibilities of simultaneous variation in both clearly discerned form and in colour are greater in it than in any other of our favourite flowers. In the Rose and the Begonia, for instance, though of course the variation of seedlings is infinite in form and in colour, yet in form the variation is not that of one simple outline, as in the Narcissus. Orchids fall into a different category, being plants neither for the open garden nor for everybody, and though their modification of form and colour is limitless, yet it lies in smaller and far more complicated detail.

To put the matter in another way, the Narcissus is perhaps a unique example among flowers of the extraordinary diversity that may be effected by a few simple elements. In form, the structural elements of the Narcissus may be reckoned as two only. The tube and corona conjointly form one cone, lying horizontally with its apex at the ovary, and the form of the whole flower depends principally upon the position upon this cone of the sepaline whorl or perianth. Thus, in *N. cyclamineus* the perianth is retired almost to the ovary, this flower being almost tubeless; while in *N. poeticus* and *jonquilla* the perianth is advanced right up to the very rim of the corona. Between these two extreme forms innumerable others are produced by the simple movement backwards and forwards of the perianth. Further variety is supplied by the dilation or contraction of the mouth of the corona, by the changing width of the perianth divisions, and by their angle with regard to the longer axis of the cone.

The colour elements are only white, yellow, and red, the last restricted to the corona and in amount. But of these we have many whites—clear-white in the poeticus, whites of green or creamy tone, and pink-whites in the cup of some of the Leedsii section. In yellows there is a very extensive range, and yellow is a large and most satisfying colour. The reds are beautiful, lying between orange and almost pure vermilion.

It is also noteworthy that of the species available for cross-breeding, two only have practically been answerable for all our garden forms. The Tazetta the jonquil, triandrus, Corbularia and others, have yielded hybrids, but all the "Daffodils" of general value and popularity in garden and market are either trumpets or poeticus, or the intermediate progeny of these two. And every link in the endless chain which they forge is a separate study in clear-cut outline and simple but subtly-graduated colour.

The story of the red colouring in Narcissi is interesting. It all originates from the narrow edge or thread of purple, or almost brown, which rings the eye of *N. poeticus*. This is a concentrated pigment of great potency, but not readily released or diluted into a "wash" of colour. Nature has, however, effected this in *N. p. poetarum* and similar flowers which occur sparingly in the high Pyrenees and elsewhere where *N. poeticus* abounds. In these the colour is no longer confined to the extreme rim of the corona, but suffused more or less throughout it. Such flowers transmit their character of suffusion to their hybrids, hence the race of red-cupped *N. incomparabilis*, whose varieties intercrossed or re-crossed with the poeticus yield flowers of intensified or accumulated colour.

Crosses between these red-crowned flowers and the white Daffodils, *N. cernuus*, *albicans*, *Leedsii*, &c., produce the tints known as citron, salmon, apricot, and peach—a very refined and exquisite range of colour. A curious fact in this connection is that the creamy-white *N. triandrus*, though it sets seeds freely by or upon such red Narcissi, nevertheless invariably eliminates the colour, the resulting seedlings never showing even a trace of red. And if a white trumpet is crossed with a poeticus having the crown not

diffused but only edged with colour, the progeny is often a flower of quite self-white in cup and perianth.

A very large amount of material and time would be necessary to enable a worker to confidently formulate a rule about the transmission of characters by the seed and pollen parents respectively. The attribute of prevailing colour is, perhaps, derived from the male principally in the *Narcissi*; that of form seems fairly well divided between the two parents. Occasionally, however, the male entirely effaces the female; thus in seedling beds from *Ajax* by pollen of *poeticus*, there will sometimes be found plants of quite pure *poeticus*, while no instance of the converse has been detected. The white perianth of

growers know that almost every variety, even the large trumpets, such as *Emperor* and *Empress*, occasionally bear two flowered scapes. But crosses between single-flowered *Narcissi*, e.g., *Ajax* and *poeticus*, not very uncommonly yield permanently two-flowered forms. Such flowers as *Emperor* and *Empress* might well be considered of distinct character and separate descent. But among the seedlings from self-fertilised *Emperor* there will sometimes appear flowers almost the facsimile of *Empress*, and *vice versa*. This was a great puzzle until a son of Mr. Backhouse, the raiser of both, told Mr. Egleheart that his father raised both from one seed-pod. Forms which have been fused together to

raiser of *Narcissi* is that of time. He is commonly asked the question, "How long does it take to flower a seedling?" and the answer is, "Four years at the least, usually five, sometimes six." But experience shows more and more that to this reckoning even as many as three or four more years must be added for the presentment of the flower and the whole plant in its matured and perfect condition. A seedling may have been increased to a row of a dozen or more bulbs before this final development takes place, and it often comes quite suddenly. The moral, of course, is, that no seedling possessing any one good character of size, form, or colour should be hastily rejected, since its deficiencies will often be made good in time. Flimsiness and narrowness of the perianth-divisions is a usual character of incipient seedling flowers.

The *Narcissus* has by no means neared its limits of development. The whole of the varieties at present in extensive cultivation are the seedlings of the first two men who touched the subject, and it has been made abundantly apparent that they did not reach the goal in size, in form, or in colour. The market still calls out for bold flowers of purer white, and for more vivid reds, and it is strange that *N. poeticus*—surely the most beautiful part of the whole genus—is represented in common cultivation by about four varieties, which are simply wild plants as collected, untouched by man's skill.

SHOW AURICULA ABBÉ LISTZ.

WE have in this new variety of Mr. J. Douglas' raising a plant of robust constitution (fig. 108), throwing a large truss of fine green-edged flowers. It belongs to a class of which there are few superlatively good varieties, and to which the Abbé is an admirable addition. The variety was well show by an amateur, Mr. Sargent, of Cobham, it being the premier Show Auricula at the National Auricula and Primula Show at the Drill Hall, April 26 (see our report of the same in the issue for April 30, p. 271). Our artist has slightly idealised the flower as then shown.

HOME CORRESPONDENCE.

THE LOST ONION TRADE.—I am obliged to your correspondent, "A. D.," for his interesting notes on p. 237, and have no doubt that the small culture and combination therein mentioned have done much to account for the unusual development of the export Onion trade of Brittany. I am told that our Bedfordshire growers have, to a large extent, given up the cultivation of Onions, but whether this is in any way due to the competition of the French producer or to other causes, I am unable to say. That very heavy crops may be grown with good cultivation is amply proved from the figures given by "A. D.," at p. 237. Undoubtedly the purchase of manure at a cheap rate should very much influence the growth of the bulb. Where this can be bought cheaply, as is the case with London stable-dung, and this can be conveyed by canal or railway, and put on the land direct at a cost of less than 5s. per ton, districts having a good natural soil, and served by the one or the other means of conveyance, offer favourable opportunities for profitable Onion culture. Onion growing, if combined with Strawberries, and the plants treated as annuals, as suggested by "A. D.," should prove highly profitable. The communication from a correspondent on p. 244 opens up altogether another aspect of this interesting question. Free trade is acknowledged to be for the general benefit of the masses in this country; at the same time it seems only fair that we should threaten to put a duty on Onions, as your correspondent says, "to be kept on until the Grape-duty be taken off." May I suggest that a "Roland for an Oliver" should write to his representative M.P., and place the two sides of the question before him, and let your readers know the reply. *C. Herrin, Dropmore.*

—It is probably in error that so much is made of the French share in our annual importations of this vegetable. The various arguments based thereon, do not therefore really apply. I have only the figures before me of importations in 1895, totalling about 5,700,000 bushels, the French share being only 576,000; whereas Holland contributed 1,400,000; Germany, 361,000; Belgium,

FIG. 108.—MR. J. DOUGLAS' NEW GREEN-EDGED AURICULA ABBÉ LISTZ.

poeticus is a very persistent character; if a yellow self-coloured trumpet is crossed with *poeticus*, quite four out of five of the resulting seedlings (*N. incomparabilis*) have white perianths, no matter which way the cross be made, though the colouring of the corona may be intermediate or follow the pollen parent. The offspring of a robust and a weakly parent may be stronger even than the stronger parent. Thus the white trumpets are notoriously difficult to make thrive in most English gardens, but crossed with *poeticus* they give rise to the race of *N. Leedsii*, many of the varieties of which are plants of more robust habit even than the *poeticus*.

Instances of reversion are common in seedling *Narcissi*, and present points of interest. There are reasons for supposing that the oldest type of *Narcissus* was rush-leaved and bunch-flowered. All large

form an ancestor appear separately, and in a curiously interchangeable form, in its descendants. Some wild *Narcissi*, from uniformity of environment through a long period of time, have become perfectly stable, and in their natural habitat reproduce themselves precisely from seed. Our own wild Lent Lily is an instance in point, and the splendid *N. maximus* seems not to vary at all where it grows wild; but this stability is at once upset by a new environment, and the changed conditions of cultivation. Brought to an English garden, *N. maximus*, fertilised with its own pollen, gives seedlings greatly divergent in character from the type and from one another. Therefore, it is rarely or never possible to secure the fine form and colour of this flower in hybrid derivatives.

A consideration which presses heavily upon the

326,000; Portugal, 343,000; Spain, 1,577,000; Egypt, 1,089,000; British Colonies, 42,000; Sundries, 16,000; total bushels, 5,730,000. I have placed Holland and Germany in juxtaposition, as there is probably a doubtful factor in all Board of Trade returns concerning Germany. It is just possible that because the Rhenish part of Germany can only advantageously export to England via Rotterdam, with a small portion via Belgium, the Dutch and Belgian totals are swelled by a preponderance of German products. The so-called German total might only comprise direct importations from German, North Sea, and Baltic ports. The total importations of Onions into this Kingdom were 5,735,000 bushels in 1896, and 6,108,000 bushels in 1897. I have at this moment not the shares from each contributory country, and hardly think the proportions would be seriously affected. *H. H. R., Forest Hill.*

SPORTIVE CYCLAMEN.—I have had sent me as curiosities Cyclamen blooms, one white and one rosy-red, both declared by the sender to have been produced from the same corm, which I am informed carries twenty white ones and ten red ones, open at once. Is this a rarity, or do Cyclamens sport in this way? Of course, there is the possibility that two tiny plants may have been pricked up together originally and grown on, the corms fitting each other so closely that an ordinary observer would not detect the division. But as favouring the stated sportiveness, is the fact that the flowers resemble each other absolutely in size, form of petal, length and colour of stalks, &c., whereas were they from diverse corms some undoubted distinctiveness other than colour might be looked for. The matter is interesting, and I should like to learn from extensive growers of Cyclamen whether such sporting is common or otherwise. *A. D.*

PROTECTING PEACH-TREES WHEN IN FLOWER, ETC.—Being in Perth lately, I called at Oak Bank. The clever gardener there (Mr. Laurance) pointed out to me a fine Peach-tree growing against a stone wall facing due south. It was one mass of bloom, and had never failed to produce a good crop of fruit. He attributed his success to never covering the tree when in flower, which corroborates my own experience in different counties. When the Duke of Norfolk sold his estate at Worksop Manor, John Stevenson, who trained the wall-trees there, was transferred to Arundel Castle. When I went there as a young man to be foreman, John Stevenson had been there about four years. When he went there the trees were in a miserable condition, for which the climate had been blamed, but four years afterwards they were without exception the finest-trained trees in England. John Stevenson said, when at the Worksop Manor, they were at great trouble in protecting their Peach-trees when in flower, but there happened to be one tree where the covering did not reach, and that tree never failed to produce a good crop. In future no more covering was adopted there or at Arundel. John Stevenson said if gardeners would only leave one tree uncovered to see the result, they would at once abandon the practice of covering either with nets or glass cases, which makes the bloom tender and keeps the bees from them. John Stevenson always adopted the plan when the Peaches were gathered, to go over all the trees and cut off half the leaves, the remaining half being sufficient to mature the bud. This allowed the sun to ripen the wood, which got so brown and hard, and the leaves remained longer on the trees. The old barbarous system was to take a Birch-broom and wipe them off. When the late Mr. Ingram finished the new gardens at Frogmore, the Earl of Surrey, who was then Master of the Household, invited Mr. Ingram to visit Arundel and see the wall-trees. He at once wanted a man from Arundel to train his young trees and manage all the out-door fruit. He engaged John Powell, who succeeded me as foreman, where he spent his lifetime. I never covered my wall-trees at Sandringham. Worksop Manor was also famous for pyramidal Pear trees; merely drive three Oak posts into the ground 8 inches above the soil, and place an iron hoop, 3 feet in diameter, on the top, secured by a staple. Select standard trees, 6 or 8 feet in height. Tie the lower branches down to the hoop. Always take care of the principal leader, merely shorten it back every season to the length required to furnish the tree. When the trees are about 18 feet in height cut out the leader. When I finished the new gardens at Sandringham, I planted rows of them across the gardens about 80 feet apart; they were much admired. They were planted 8 feet apart in the rows. I may add that when at Oak Bank

I observed one of the finest Wellingtonias which I have ever seen. The height was 75 feet, and the girth 15 feet in circumference 4 feet from the ground. It grows in a sheltered corner on the turf, behind the garden-wall. Mr. Laurance told me that the roots had got under the foundation of the wall and extending down the garden. *William Carmichael, 14, Pitt Street, Edinburgh.*

GRAFTING WITH A STRIP OF BARK CARRIED OVER THE END OF STOCK.—The mode of grafting practised by fruit-growers in Botes Fleming parish, near Saltash, has not been illustrated in your valuable paper, nor does Mr. Wright mention it in his fruit-grower's guide. [This mode of grafting was illustrated in the *Gardeners' Chronicle*, March 27, 1897. Ed.] I have used it for fifteen years for all except large stocks, that are better rind grafted where two to four scions are required to carry the sap. It most nearly resembles saddle grafting, and is called slip-and-tongue. I enclose two photos; No. 1 shows two unequal heads of a grafted tree. The tongue of that on the left failed to grow, and the bark does not cover the wound. The tongue of that on the right grew, and though that part of the stock is more than twice the size of the other, the union is complete—grafted March, 1896. No. 2, a budded tree of New Hawthornden, was grafted at the same time, and bore three fruits in 1897 of Northern Greening. The union where it was double grafted, in 1896, is complete, but the wound where the stock was cut off in 1892 is still open. [The photographs sent by our correspondent clearly show these points. Ed.] Three maiden trees planted in November, 1892, all have open wounds. Does not this show that grafting is superior to budding? The slip should be two-thirds of the graft, the tongue one-third, and should only touch the stock with the bark, showing the wood of stock between the ends of the bark. If the tongue unites, the graft is pretty safe from wind-shaking, and requires no staying, and there is no snag to be cut off next year, as there is in whip grafting. Allen's Everlasting Apple I have not seen mentioned by your correspondents as a good late Apple, and of good flavour; we have a few dozen left. [See R. H. S. Report in last issue of the *Gardeners' Chronicle*.] It is a certain and abundant bearer, and has been kept till the middle of June. Sturmer Pippin and Claygate Pearman Apples generally keep well on into May, and Uvedale St. Germain Pear. *H. R.*

LATHYRUS SIBTHORPII.—*L. Sibthorpii* (Baker) is a dwarf and elegant form of everlasting Pea, now, at the end of April, in full flower in my garden. Its botanical history is a little confused. It was given me by Mr. Archer Hind about twenty years ago. He had it I believe from the Botanical Garden at Oxford, where it had perhaps been cultivated ever since Sibthorp's time. Sibthorp does not seem to have distinguished it from *L. latifolius*, and the name, *L. Sibthorpii*, was first authorised by Mr. Baker, who described it a few years ago in the *Gardeners' Chronicle* from a specimen sent by Mr. Archer Hind. Since that time it has been identified with *L. undulatus* (Boissier), *Flora Orientalis*, vol. ii., p. 611, and this name, given to it on account of the wavy outline of the pinnæ, is now accepted as its true botanical name. E. Boissier says it is found wild near Constantinople, also in Bithynia. There is a very good portrait of it in Sweet's *British Flower Garden*, Series II., vol. iv., t. 333, as *L. rotundifolius* var. *ellipticus*. This was taken in 1838 from a specimen in the Birmingham Botanical Garden, and both figure and description correspond exactly with my living plants. *L. undulatus* is also figured and described in the *Botanical Magazine*, t. 9499. The plant is scarce in nurseries, even if it has ever reached them; I have seen both *L. rotundifolius* and *L. tuberosus* exhibited as *L. Sibthorpii*, but the true plant is now becoming less rare in gardens, Mr. Thompson, of Ipswich, having distributed many which he raised from seed. I have found it a little tender; at any rate, it prefers a warm spot against a south wall. It is well worth growing for its very early and abundant flowering, six weeks or more before any other form of everlasting Pea, and bright in colour, resembling *L. latifolius* in miniature. *C. Wolley Dod, Edge Hall.*

PEAR TRIOMPHE DE VIENNE.—I was glad to see a notice of this fine Pear in your paper. It was put into stock in 1880, and has proved a great addition to early autumn fruits. The growth is moderate, and it crops freely on the Quince as a pyramid or cordon, and grows very stoutly on the free stock. The fruit is the shape of the old Cuisse Madame (Windsor), but the skin is of a rich rough russet-brown, which gives it a handsome appearance. It grows to $\frac{3}{4}$ lb. in

weight or over if well thinned, and the flavour is very fine; but it will not keep, and if left on the tree too long it becomes mealy, but when fully developed it should be gathered and placed in the fruit-room for a few days, when it is juicy, refreshing, and carries a rich flavour. *G. B.*

M. TRUFFAUT'S ARTIFICIAL MANURE CARTRIDGES.—I have read with much interest your remarks on the above in your issue of this date (p. 264). I am pleased you are so favourably impressed with the system, and you may be glad to know I have been experimenting in a somewhat similar line for some considerable time past. Mr. Truffaut's inventions have been guarded by provisional protection, and I am now securing a patent. The manures are absolutely free of all merely bulk-forming or weight-giving ingredients. They are the pure essence of plant-food. The cases are more congenial to the roots and nourishing to the plants than any metallic substance, but you and your readers will learn more later of their excellent properties and exceeding conveniences. *J. Muir, April 30.*

APPLE GLORIA MUNDI AND OTHERS.—Having known this sort for forty years, I am not able to speak in its favour. When grown as a standard, it produces a few perfect fruits, the others being one-sided, and very uneven on the Paradise stock. It gives excellent examples, but only a very few of them, while it is true it makes a grand dish of showy fruit for exhibition. I cannot recommend it for general culture, as so many are better in all respects—say, Tower of Glamis, the little-known Belle de Pontoise, Newton Wonder, and Alfriston. On the Continent it is generally called Belle Dubois, and has also found its way here under several other names. King of Tomkins Co. is yet grand in our fruit-room. *Geo. Bunyard.*

TOMATO CONQUEROR.—Whilst some persons seem to be perpetually experimenting with manures of diverse description in relation to Tomato production, and appear to leave matters after all very much where they found them, growers of experience go on in their own way, giving their own treatment and general culture, and somehow producing remarkable results. Just recently, when looking through the Cucurbit and Tomato-houses, Mr. T. Mortimer employs with such admirable success at Farnham, I could but be struck with the appearance of 200 plants of the variety of Tomato named above—Conqueror—which is there grown for earliest cropping. The variety is of the corrugated order, though not severely so, for it is found that only this section is of any service for market-culture during the winter. Each plant was in an 11-inch pot, stood in rows of five on the soil-floor, all down one side of a long span-house, and some 2½ feet in height, having been stopped so soon as the required number of racemes of fruit had been set. It was thus possible to see a great portion of the entire crop at a glance; and, indeed, it was a remarkable one, the plants seemingly being all fruit. Colouring had just begun. It was expected that the whole would be fit to gather in three weeks when out the plants would go to make room for others well advanced, to be this time planted out for vertical culture during the summer and autumn. The exceeding abundance of fruits on each plant, dwarf as it was, showed that this variety, Conqueror, is a capital setter. The seed from which this stock of plants was raised was sown about November 1 last. The soil compost is of an ordinary loam, with some well-decayed manure added, and a 48-potful of Thompson's Vine-manure per barrowful. When first put into the large pots, some 4 inches deep room is left for two top-dressings of soil, at which this manure is used in the same proportion. An occasional watering with soot-solution is also given. No treatment can give better results. *A. D.*

VERONICA ANDERSONI VARIEGATA.—We find the above named variety of Veronica an excellent one for flower-garden decoration during the summer, having used it for that purpose many years. In wet districts it is more useful than silver-leaved Pelargoniums, and requires much less care in propagation and storing through the winter. When associated with purple or blue-flowered Violas, Salvia patens, or Verbena *venosa*, it has a good effect. It is easily propagated by cuttings in the same manner and time, putting them in as with bedding Calceolarias, viz., about the first week in October; we make use of a cold pit constructed of old railway sleepers, and covered with glass sashes. The cutting bed is somewhat below the level of the surrounding ground, and

s made up of spent soil from the potting-shed with a thin layer of river sand on the surface. The cuttings consist of side-shoots of the old plants cut off at a joint, and leaving about three pairs of leaves. They are inserted in rows 3 inches apart, and about the same distance in the row. Fully 90 per cent. of them form roots. During frosty weather the sashes are covered with a mat, and over this some stable-litter. The outside of the pit is also banked round with coal-ashes. With these precautions, the cuttings are quite safe in the winter. One great advantage in using this *Veronica Andersoni* variegata in bedding is, that the plants can be put in their permanent places in April; and I have to-day, April 16, planted out some hundreds in the beds. I usually insert a few small branches of common Yew or Spruce in the bed as a slight protection against cold winds. Those of your readers who have much bedding out, and who are not over supplied with labour, will at once see the benefit of using half-hardy plants like this one in question. *H. J. C. Grimston, Tadcaster.*

LAW NOTES.

Re H. T. DARTNELL, STATIONER, FORMERLY NURSERYMAN, CHELTENHAM.

THE public examination of this debtor was held on Thursday last at the Cheltenham Bankruptcy Court, before the Registrar. The debtor, in reply to questions put by the Official Receiver, stated that he formerly carried on business as a nurseryman at Charlton Kings, and latterly he had carried on a stationer's business in High St., Cheltenham. He had filed a statement of affairs, showing liabilities amounting to £676 4s. 7d., and assets estimated to produce £237 5s. 1d. The Official Receiver, however, stated that the assets would not realise the amount estimated by the debtor, as the stock-in-trade, which he estimated to be worth £225, had been sold for £136. Debtor further stated that he was forty-seven years of age. He had no capital of his own when he purchased the nurseryman's business at Charlton Kings four years ago. He sold it about a year ago for £1000, and from the proceeds he repaid the £700 he borrowed when he started the business. With the remaining £300 he purchased the stationer's business in High Street, of the Official Receiver, the previous owner having become bankrupt. The reason he gave up the nursery business was because it did not pay. When he said he received £300 nett from the sale of the nursery business, he did not include the trade debts. He should think he owed between £800 and £900, outside the £700, borrowed capital. As a matter of fact, he was insolvent when he purchased the stationery business. Before filing his petition, he called a meeting of his creditors, but very few attended, and upon an execution being levied on his effects, he filed his petition in bankruptcy. Eventually the examination was ordered to be adjourned for a month, to enable debtor to file certain accounts.

SOCIETIES.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

APRIL 28.—On this occasion the chair was filled by W. THOMPSON, Esq., and there were present Messrs. G. S. Ball (Vice Chairman), A. Warburton, D. B. Rappart, G. W. Law-Schofield, H. Greenwood, J. Leeman, R. Johnson, E. J. Sidebotham, W. A. Gent (Hon. Sec.), and P. Weathers.

A very interesting feature of the meeting was a display of handsome and rare hybrids from Messrs. JAS. VEITCH & SONS, which included *Cattleya* × *Philo* (C. Mossiae × tricolor), *Laelio-Cattleya* × *Ascania* var. *superba*, a charming thing, produced from *Laelia xanthina* × C. *Trianaei*; the sepals and petals are of a rich buff colour, and there was the faintest trace of rose in the lower portion of the lip (Award of Merit). Another choice plant, of which four varieties were shown, was *Epidendrum* × *elegantulum* (E. *Wallisii* × *Endresio-Wallisii*); some of the varieties were heavily punctured with tiny dark brown markings, while others had yellow or bronzy segments, which were spotless. *Zygopetalum Perrenoudi* (Z. *maxillare* × *intermedia*) was given an Award of Merit, which it well deserves, as it proves an acquisition to a not over-rated group; the prevailing colour is a deep bluish-violet, and on the lip there is a faint white reticulation. *Cattleya Schroderae* *amabilis*, shown by the same firm, hardly received justice from the committee in the

Award of Merit given. It is, undoubtedly, one of the finest forms of *Cattleya Schroderae* extant, the labellum measures nearly 3 inches across the front, and the flower altogether cannot fail to strike the beholder. *Laelio-Cattleya* × *Wellsiana* was not noticed, the form of the flower being by no means pleasing. *Laelia Latona* (L. *purpurata* × *cinnabarina*) gained an Award of Merit, several good forms were shown; *Epiphrontis Veitchii* is a good Orchid, and worth the hybridiser's trouble; the same can hardly be said of *Cattleya* × *Laure-Mossiae*. Mr. D. B. RAPPART received an Award of Merit for *Dendrobium nobile* "Hutchinson's var."

Messrs. LINDEN, Brussels, staged a magnificent lot of *Odontoglossums*, which really spoil one for choice. Magnificent things they were, all of them, the only fault was that too many were sent. The best was *Odontoglossum Wilckeianum* var. *Lindenii*, a dream, carrying a spike with fifteen flowers the groundwork of which was a pale yellow, with intense crimson markings (First-class Certificate). *Odon.* × "Princesse des Canaries" received an Award of Merit, the flower appears to be almost an "albino" of *Odon.* *luteo-purpureum*; Messrs. Linden think not (Award of Merit). *Odon.* × *versicolor* looks like a natural hybrid of *O. crispum* × *O. Coradinei*. *Odon.* *crispum* "Princess Clementine" is a charming little thing, but as the committee saw it to disadvantage it received an Award of Merit only. *Odon.* *Ruckerianum* var. *lilacina* was voted an Award of Merit, and when better established will prove one of the best. Mr. DUNCAN GILMOUR (gr., Mr. Day) received an Award of Merit for *Cattleya Mendeli* "Dorothy Gilmour." Mr. E. J. SIDEBOTHAM (gr., Mr. Shine) showed a very good form of *Dendrobium Venus*, for which an Award of Merit was given. Mr. JAS. CYPHER staged a handsome and valuable *Odontoglossum crispum* called *O. c. Cypheri*, flowers of good size and shape, well marked with a profusion of tiny rosy spots in the centre of the petals; this plant remained in the Manchester district.

The Ven. Archdeacon RAWSTORNE gained an Award of Merit for a very nice variety of *Cattleya Trianaei*. Mr. G. S. BALL (gr., Mr. Hay) received a First-class Certificate for a splendid form of *Cypripedium Lawrenceanum* var. *Hycanum*, a fine bold flower which was generally admired. An Award of Merit was given to the same amateur for *Odontoglossum Rossi majus* var. *rubescens*, and also for a well-grown plant of *Dendrobium atro-violaceum*.

Mr. T. STATTER (gr., Mr. Johnson) exhibited *Cypripedium Lawrenceanum* var. *Hycanum*, which also received a First-class Certificate; and from the same collection came a well grown *C. caudatum* var. *Wallisii* (Award of Merit). Mr. G. W. LAW-SCHOFIELD sent a magnificent plant of *Cypripedium* × *Schofieldiana*, which was submitted to the committee at a previous meeting as an easy subject to grow; this appears to be the hybrid *par excellence*, the plant exhibited having ten growths and three flowers showing. Mr. J. ROBSON had a few nice varieties of *Odontoglossums* and *Cattleyas*. Mr. H. GREENWOOD put up a small group which had good things in it, a fine *Lycaste Skinneri* *alba*, *O. Humeanum* "Greenwood's var.," *Dendrobium nobile* *Highfield* var., a good *Odontoglossum nebulosum*, and *Dendrobium Hildebrandtii*. P. W.

ROYAL HORTICULTURAL.

Scientific Committee.

APRIL 26.—Present: Dr. M. T. Masters (in the chair); Professor Müller, Rev. W. Wilks, and Professor G. Henslow, Hon. Sec. *Vine Leaves with Gummy Exudation*.—Some leaves were received from Mr. F. M. Gulrin, Iscoed, remarkable for a stickiness. This appeared to be attributable to green-fly, although none was present. The exudation is the result of puncture. *Pæonies, Decayed*.—Mr. F. F. Freeman sent some leaves which appeared to have decayed at the junction with the stem. They were forwarded to Dr. W. G. Smith for examination for the presence of fungi. *Growth of Ribes coccinea*.—Mr. Henslow described a rather curious case of a bush growing by the south side of some palings, that had sent up a number of shoots on the north side. The shoots on the southern half were in full leaf, bearing very few racemes; while those on the other side were covered with flowers, the foliage being scarcely apparent.

Obituary.

MR. LYNCH WHITE, JUNR.—It is with much regret that we learn of the death, at Bournemouth, on the 2nd inst., of Mr. Lynch White, Jun., of Home-field, Bickley, Kent, one of the partners in the Thames Bank Iron Co., Upper Ground Street, S.E. Mr. White, who was in his 47th year, and had been in failing health for some time, was the only son of Mr. Lynch White, Senior, Leigham House, Streatham Hill, S.W., who, about the year 1850, established the extensive horticultural heating and engineering business, which has since been carried on in Upper Ground Street. In 1872, Mr. White, Senior, retired from the business in favour of his son and Mr. William Yates Baker, who have, since that date, traded under the title of the Thames Bank Iron Co. The deceased, who was a member of the St. Andrew's Lodge (No. 231), and one of the founders of the Hortus Lodge (No. 2469) of Freemasons, was of a kindly but shy and retiring disposition, and much respected by those who knew him personally. Much

sympathy is felt in the trade for his widow and family, and no less so for his surviving partner.

A. BLICK.—Many readers of this journal will learn with regret of the death at Brentford of Mr. A. Blick, in his seventy-second year. The deceased was for a period of twenty-five years in the employ of the Royal Horticultural Society, acting as foreman under the late G. Eyles and Mr. A. F. Barron, in the gardens at South Kensington, and was much respected.

MR. JAS. CHAPMAN.—On the 4th inst., after a long illness, Mr. Jas. Chapman, aged 71 years, a well-known and valued employé for over twenty years of Messrs. J. Laing & Sons, Forest Hill Nurseries, London, and formerly with the late Messrs. Rolison of Tooting.

MR. W. H. CULLINGFORD.—The recent death at an advanced age of Mr. W. H. Cullingford at Tunbridge Wells, removes from our midst an ardent and enthusiastic florist, who was a generous supporter of many societies which encourage the culture of popular flowers, and especially of the *Chrysanthemum*. The popular variety *Cullingfordi* was named after him. The name of Mr. Cullingford will go down to posterity as intimately connected with the introduction to English gardens of the *Cactus Dahlia*, *D. Juarezii*. Towards the close of the seventies Mr. Cullingford obtained plants of the *Cactus Dahlia* from Messrs. Anthony Roozen & Sons, of Overveen, Haarlem, and from him it passed into the hands of Mr. Henry Cannell, nurseryman, Swanley, by whom it was exhibited for the first time at the Alexandra Palace, Muswell Hill, on Sept. 3, 1880. Mr. Cullingford lived long enough to see this interesting stranger develop into forms and colours which at one time would have been inconceivable. R. D.

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

NORAH FRITH would be greatly obliged if any reader of the *Gardeners' Chronicle* would kindly advise her under the following circumstances. My employer, she states, has a large pond bath, cemented at the sides and bottom, quite open, which is supplied from a perennial spring; the water, coming through clay, is very hard. Throughout the summer a green scum arises from the bottom, and I am inclined to the belief that the hardness of the water is the cause of it, although in the winter the scum does not spread. Can you suggest anything that would stop it—salt, soda, or any such thing? [If the pool could be covered over, and light excluded, the plant would soon disappear. ED.]

AFFILIATION: W. B. There are the National Amateur's Association, L. Brown, "The Cottage," Seven Arches, Brentwood, secretary; Nottinghamshire Horticultural and Botanical, J. M. Stewart, 16, Market Street, Nottingham, secretary; Manchester Horticultural and Improvement, W. B. Upjohn, Worsley, Manchester, secretary; Leeds Paxton, Joseph Smith, Asket Hill, Leeds, secretary; Devon and Exeter Gardeners' Mutual Improvement Association, A. Hope, 54, High St., Exeter, secretary. There are many more, for the titles of which, and the names and addresses of the secretaries, we must refer you to the *Horticultural Directory*.

A WET STROKEHOLE: E. A. C. Make the walls and floor with concrete, and face this with Portland cement. If it must be used under water, employ the so-called hydraulic lime-cement. The proper proportions for making hydraulic lime-concrete are as 12 of ballast to 2 of lime.

ANTS ON PEACH: F. T. These insects sometimes devour the stamens and stigmas, and render the blooms infertile; and it is well to prevent their access to the trees. You might place a lath close to the wall raised 6 inches from the earth, and coat it with tar, and round the stem affix a thick band smeared with the same, care being taken that no tar gets on to the bark. Find the ant's nest, and dig it out, or smoke out the inmates.

BACK NUMBERS: *W. B.* We cannot undertake to furnish gardeners' societies with copies, as, owing to their large increase in numbers, to do so would become an onerous undertaking.

BARBE DE CAPUCINE: *G. H.* Cultivated Chicory.

BLACK CURRANT BUD-MITE: *T. F.* The mite is invisible to the unaided sight, and it has nothing whatever to do with the "looper caterpillar" that you found in the buds.

BOOKS: *Jason.* *Garden Craft Series*, by L. H. Bailey; Macmillan & Co., New York and London. Price, a few shillings.—*T. Smith & Sons.* A manual on Peach Culture, by D. T. Fish, sold by Mr. Upcott Gill, 170, Strand, W.C.

CARRIAGE OF BASKET OF GRAPES: *F. S.* The case being pending, you can only await the judge's decision.

CENTAUREA CANDIDISSIMA: *J. M.* You might make the following mixtures:—*Centaurea*, planted at about 15 inches apart, with *Verbena venosa* alternately, to be followed by Truffaut's *Pæony*-flowered *Asters*, raised from the beds in the reserve garden, or grown in flower-pots; zonal *Pelargoniums*, intermixed or edged with *Centaurea*. *Zinnia Haageana* in mixed colours might be used instead of the *Pelargoniums*. The tall *Ageratum mexicanum* or rich-coloured *Petunia hybrida* look well on a carpet of *Centaurea*, as do tuberous-rooted *Begonias* if bordered with the plant. In fact, the uses of *Centaurea* in conjunction with other plants are almost endless.

CHRYSANTHEMUM: *Anxious.* The leaves sent show two distinct modes of discoloration. One leaf has dry, withered spots, measuring up to about $\frac{1}{4}$ inch diameter; these are caused by a fungus (*Septoria*). Leaves like this should be at once picked off and burnt. The other half-dozen leaves do not show spots of this kind. The discoloration in their case begins in a number of reddish-purple spots, which soon become withered in the centre, generally on the upper surface only; ultimately these spread and form a brown scurf. This disease we cannot trace to any fungus. It may be due to insects—green-fly was seen on the leaves sent. Has any insecticide or other chemical been sprayed on the leaves? This might also start the spotting. Look to general cleanliness, and do not force too hard; give more air and a drier atmosphere. Beyond the discoloration, we do not anticipate much harm to the plants. *W. G. S., Leeds.*

COVENT GARDEN MARKET LIST: *Jason.* It is sufficiently long in its present abbreviated form. Space does not admit of everything being mentioned; moreover, the flowers named by you are, as yet, not generally in the market. It is too early, especially so for *Gladiolus gandavensis*; although *G. Colvillei*, *psittacinus*, and other early species might be found in small quantities.

CUCKOO-FLOWER: *Subscriber.* *Cardamine pratensis*, also called Lady's-smock.

CUCUMBERS: *A. J. R.* The worst case of mildew that we have had under our notice for a long time. Clear out the whole of the contents and char them. Thoroughly disinfect the house with burning sulphur, lime-wash the walls, and make a fresh start.

DISEASED PRIMULAS: *C. W. D.* With regard to Primulas from Edge Hill, "The Primulas are attacked by Nematode worms. These are present in numbers just where the decayed parts border on the living tissues. They seem to have begun on the youngest leaves of the rosette, and to be now eating their way into the root-stock. An attack carried out thus would soon kill the plants." *W. G. S., Leeds.*

EARLY STRAWBERRIES: *F. T.* Black Prince, very early, but small; King of the Earlies, medium size, rich and sweet flavour; Noble, large and handsome, plant prolific; Vicomtesse Héricart du Thury, medium size, solid, well flavoured, abundant bearer; La Grosse Sucrée, large, dark red, good flavour, good cropper; Gunton Park, pleasant, brisk flavour, form, and of good colour. These turn-in in the order of their name. Four to five ounces per plant of early-forced plants is the utmost limit of a crop of, say, Noble, King of the Earlies, and La Grosse Sucrée.

FIRST TRUSS ON A TOMATO PLANT: *Jason.* This truss or cluster of flowers would, if the plant had not been crowded with other plants, and had full sunlight, come about 1 foot from the ground, but

the first blooms, i.e., those nearest the ground, often prove abortive. Very likely depressing the stem and keeping laterals rigidly cut off might help the formation of a strong fertile cluster of blossoms at that point.

FLORA OF NORFOLK: *T.* *The Flora of Norfolk*, by Rev. Kirby Trimmer (London: 1866).

GRUBS AT PÆONY ROOTS: *W. H. Page.* The grubs were dead and rotten when received. They appear to be those of the small "Swift" moth (*Hepialus*), but this is not quite certain owing to the condition in which I received them. Lift the plants and pick out the grubs and chrysalids. But the mischief is done for this season. Dressings of lime-water late next autumn might stop an attack for next year. *R. McL.*

JAPANESE PORTFOLIO, WITH COLOURED PLATES: *Jason.* We have no knowledge of this work.

MILLER'S "GARDENERS' DICTIONARY," WITH COLOURED PLATES, 1807: *G. S.* No approximate price can be named. It might be anything between 15s. and £2. You would be well advised to advertise the work.

MOREA IRIDIODES: *H. E.* We do not understand your question. If you mean Natural Order, it is Iridaceæ. The plant is a native of South Africa.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*T. H. B.* *Kalanchoe grandiflora.*—*E.* *Chichester.* Violet Marie Louise, one of the best late bloomers.—*W. H. D.* *Leptospermum scoparium.*—*Mos. C.* *Holboëllia latifolia.*—*J. R.* *Oncidium aureum.*—*L.* *Bury.* *Cyrtopodium punctatum.* *F. M. M.* 1, *Oncidium crispum*; 2, *Cattleya Skinneri*; 3, *Cattleya intermedia.*—*C. W. P.* 1, *Brexia madagascariensis*; 2, *Erica ventricosa carnea*; 3, *Boronia elatior*; 5, *Erica Cavendishi*; 6, *Aotus gracillima*; 7, *Erica ventricosa coccinea minor*; 8, *Carex variegata*; 9, *Lælia purpurata*; 10, *Cypripedium barbatum*; 11, *Sansevieria zeylanica*; 12, *Adiantum cuneatum*; 13, *Adiantum mundulum*; other numbers not found.—*Wallington.* 1, *Pyrus Malus* (Crab); 2, *P. salicifolia*; 3, *Ornithogalum nutans.*—*C. A. W.* 1, *Carex variegata*; 2, *Anthericum lineare variegatum*; 3, *Reineckia carnea variegata*; 4, *Begonia Fischeri*; 5, *Sedum carneum variegatum*; 6, *Oxalis acetosella* variety.—*Subscriber, Worksop.* 1, *Boronia heterophylla*; 2, *Boronia elatior.*—*W. T.* *Geranium phœum.*—*G. J.* *Crewkerne.* 1, *Acacia cordata*; 2, *Fittonia argyroneura.*—*J. A.* 1, *Croton Mortii*; 2, *Croton irregularis*; 3, *Croton interruptus*; the *Dendrobium* is *D. moschatum.*—*G. R.* Thanks for information about variegated *Dendrobium*; we will note the fact.—*T. P. W.* 1, *Doronicum plantagineum*; 2, *Saxifraga cordifolia*; 3, *Geum* sp.; 4, *Geranium Phœum*; 5, *Lithospermum purpureo-cœruleum*; 6, *Pulmonaria officinalis*; 7, *Narcissus Jonquilla.*

ONCIDIUM CRISPUM AND O. MARSHALLIANUM: *J. T.* *Burton-on-Trent.* Let the *Oncidiums* remain where they are for a fortnight longer, and then ripen their bulbs in a cooler and more airy house. It will be safer to sow the seeds of *Cattleya* and *Lælia* on plants of similar nature, but some may be tried on the pots of the *Cypripediums*.

PALMS: *S. Hampstead.* With regard to these plants, received at the beginning of this month, I have examined and cultivated it. The pink fungus has gone on spreading till all green tissue is consumed. The fungus on *Seaforthia elegans* probably only takes hold on the decaying leaf-bases, although we have found it able to continue to kill the living parts. This being so, the leaves when removed might be cut off further down, and the cut ends painted over with tar, which would neither injure the Palms nor look unsightly. Care must be taken not to let the tar touch the healthy portions. The same could be done in the case of leaf-bases already attacked. At the same time a very dilute solution in water of some disinfectant, say, carbolic acid or corrosive sublimate, might be used occasionally to wash down the outside of the bare stems; it must not, however, be put on the living foliage. The lodging of water in the leaf-bases will favour the fungus-growth; this might be reduced as far as possible. Look also to general cultivation of plants to make them somewhat more hardy. *W. G. S., Leeds.*

PEACH-TREES AND WHITE SCALE: *Elm Park.* Nothing very effectual can be done at this season. You must wait till the leaves fall, when you may

coat the bark with thick lime wash, made with sour milk; or clay, cow-dung and sulphur, mixed with water to the consistency of "slip."

PEACH TREES IN POTS: *T. B.* The method of constantly pinching the growths of the Peach is wrong in principle, the tree not bearing like the Apricot, Plum, and Pear on spurs, but on the buds that form on the best ripened lower portion of the annual shoots. The quantity of bearing wood that you retain on your pot Peaches must be more or less in accordance with the size and strength of the plants. Having made the selection of the shoots, all others, excepting such as may be wanted to give shapeliness to the crown or to extend the tree, should be cut out entirely, leaving no anastomosing shoots. In young pot-trees, these formative shoots should be stopped at various heights as may suit the purpose in view. Every year following the selection and pruning of the bearing and formative shoots, and the removal of all others made the previous year, must be carried out in the winter, and the selection and disbudding of new bearing and formative shoots in the spring and early summer. Unless a young shoot is unduly vigorous it should not be stopped during its period of growth. If a shoot must be stopped, take it back to a lateral nearest its base, and let this shoot take the place of the part that has been removed.

PEACH-WOOD AND SHOOTS: *J. T. B.* The shoots, &c. sent show gumming, probably due to endeavour to correct excessive vigour by the use of the knife, or to the rupture of the rind of immature wood by frost. There are also present large quantities of mildew and two species of scale insects. Firstly, you must check the vigour of the tree by the removal of manurial top-dressings, if any, and by severely disbudding and laying-in the wood at wide intervals, in order to get it well ripened. Secondly, in the early autumn lift the tree and replant none of the roots at a greater depth than 8 inches, shortening the longest roots before replanting. Thirdly, get rid of the mildew forthwith by using sulphide of potassium at the rate of $\frac{1}{2}$ oz. to 1 gallon of water, or use a weak solution of the Bordeaux Mixture, or freely use flowers-of-sulphur. Fourthly, annihilate the scale by a smothering paint made with clay, cow-dung and sulphur, laid on in the early part of the winter, detaching the tree from the wall. In hard frosty weather syringe the surface of the wall with water.

PEAR, PITMASTON DUCHESS: *X.* The leaves sent are affected with the Pear-mite, a species of *Phytoptus*. We can only recommend you to burn the leaves. Spraying with Tobacco-water might be beneficial.

TOMATOS: *C. E. W.* The plants are suffering from the so-called "sleepy" disease induced by a bacterium or fungus. Nothing much is known about the malady, excepting in so far as our knowledge goes at present, that a plant affected with drooping never recovers its former vigour. Destroy by burning every vestige of the diseased plants.

VINE DISEASE: *E. D.* Your Vines are affected with a fungus allied to that causing the Potato disease. Burn the affected leaves, and spray the other leaves with weak Bordeaux Mixture, or potassium sulphide $\frac{1}{2}$ oz. to a gallon. Lose no time.

ZONAL PELARGONIUM LEAVES AND FLOWERS: *G. H.* The appearances are precisely those that would result from overfeeding. The flowers $2\frac{3}{4}$ inches wide are enormous, and one leaf measures 8 inches in diameter. You must discontinue this sort of high feeding, or the plants will get into a hopelessly unhealthy state.

RESEARCHES IN PRUNING FRUIT TREES.*

EVERY practitioner who has to do with the pruning of fruit trees, if he has studied the subject, knows how various are the views of the different cultivators who have written concerning it, many of them being diametrically opposed to each other, so that the less-experienced reader is apt to be greatly puzzled as to the course he should take. These differing opinions have their rise in the fact that the practices of the older cultivators are constantly being repeated without further proof. In recent years Herr Koopmann has published his researches and observations, extending over many years in a very excellent work, entitled *Grund lehren des Obstbaumschnittes*; or, *Principles of Pruning Fruit-trees*.

This work can be most warmly recommended to the notice of all pomologists, but as it is one that requires careful study, we can only notice here a few striking observations on subjects of every-day practice in gardens.

It is a rule of general acceptance that the hard cutting-back of a young tree results in the strengthening of the shoots, although some pomologists believe that hard-cutting weakens the tree, and consequently has the opposite effect.

Koopmann, in order to put these contradictory views to the test, carried out experiments on a row of equally-developed trees, as to the comparative lengthening and thickening of the shoots after pruning. He found that 1-year-old grafts reached their greatest length when they were not cut-back, which agrees with the view of Gaucher, that by the rearing of standard trees, they should not be cut-back. The thickening of the stem, and the production of wood is, however, not so great if the lateral shoots be not shortened. When the year's growth is relatively of sufficient strength, stems intended for standard trees should not be cut back; but when this is not the case, then cutting back must be performed. These experiments showed that the stem development was greatest when seven-tenths were cut off, leaving but three-tenths. By harder cutting back than this, the resultant shoot was shorter. Taking into consideration, however, the entire production of wood, it was found that the removal of two-thirds of the length resulted in the greatest possible strengthening of a tree. This agrees with the fact that the lateral shoots should be also cut back two-thirds of their length.

Experiments were made on pinching the summer shoots of fruit-trees, and it was found that every shoot that was pinched suffered a weakening of one-tenth as compared with the lengthening of a natural or unpinched shoot.

* The subject-matter of this article was contained in a lecture given by Herr W. Lauche, at a meeting of the K. K. Gartenbau Gesellschaft of Vienna, March 15, 1897.

The earliest is the most suitable time to pinch, or when the shoots are about 4 inches long, and only the terminal bud should be taken. If more than this be removed, the lower buds push out strongly, and the object of the pinching is defeated.

It is an important point in the management of pinched trees, that, only in the second year does a permanent weakening occur if the pinched parts are pruned, and the small lateral shoots shortened back, then the shoots remain permanently weak. On the contrary, if the pruning is performed on parts of a tree below the pinched shoots, the results and purposes of the pinching are frustrated.

We are also enlightened as to the results of Ringing. The breadth of a ring should on no account exceed 4 to 6 millimetres, this being the most suitable because the excised space gets covered in the first season; whereas narrower rings allow the bark to unite too quickly, and broader ones prevent an union taking place. A suitable time for ringing a tree is just previous to its flowering.

Especially deserving of notice are the effects of ringing on the growth of the roots; ringing forming a hindrance to the descent of the sap, the roots being thereby decidedly weakened. Beyond this we find that ringing not only weakens the branch on which it is performed, but likewise the branches below the ringed part break weaker. Ringing should not be carried out on all the branches of a tree at one time, but at the utmost on the half of them, and on naturally weak-growing trees it should be omitted.

Koopmann struck a note of warning in reference to scraping and slitting the bark, not to carry these operations too deeply into the innermost tissues of the bark, recommending slitting to be carried out over the basal enlargement of the branch as far as the stem; and he points out its importance in cases of canker caused by frost or sun-burning. He advised the cutting of parallel lines, beginning above the injured parts, deep down to the wood, and ending in sound tissue below them, this being the only method by which healthy new bark can be made to extend over an injured surface.

In order to make the so-called notching of a branch or shoot of good effect, the notch must be cut down through the bark to the wood at a point just above a dormant-bud; which then leads to the strengthening of the growths below that point, whereas if the notch be made under the bud it weakens them. Koopmann discovered that notching can be used in different methods with diverse effects on various kinds of fruits.

Important are his observations on pruning newly-planted trees. The very common practice of cutting the shoots hard back, i.e., to three or four buds, was always productive of unfavourable results, but a cutting back to one-half the length was satisfactory, and good results were sometimes obtained in the absence of all pruning, but only by such trees as possess a very compact habit of growth. And concerning the much-discussed subject of the season when to plant, Koopmann has much to say. He found that planting during winter, in the early autumn, and as early as possible in the spring, gave the best results; and the worst when the planting was performed in late autumn, and in winter just previous to the occurrence of hard frost.

In Germany, where the winters are, as a rule, of great severity, with bright sunny days, protection against frost by means of mulches,

and against sunshine, have to be used for autumn and winter-planted trees. Koopmann deprecates the planting of fruit trees in the autumn after a wet summer and autumn, the wood being in an immature condition; and he only recommends the planting of Apricots and Peaches at that season if the summer has been a warm one.

PLANT NOTES.

DOUBLE-FLOWERED PRIMULA SINENSIS.

THE named double and the semi-double flowered forms are for many purposes more serviceable than the single-flowered; although the latter are greatly improved, and almost indispensable greenhouse plants. Double Primulas will stand more heat, and the blooms when wired for bouquets, &c. are very lasting. Probably, one reason why so many grow the semi-doubles in preference to the named varieties is that they are readily produced from seed, while the latter can only be propagated by division, and they are also liable to die-off at the base. Those sent out by the late Mr. R. Gilbert would, I think, be somewhat difficult to improve upon. I well remember when working at Burghley House Gardens seeing a houseful of these plants well-grown, and a mass of flowers. There may, however, be better ones which have escaped my notice; but Lord Beaconsfield, The Marchioness of Exeter, and White Lady were the varieties grown by Mr. Gilbert at that time. The old double-flowered white *Primula sinensis* is a useful plant, with a robust constitution, the plants not rotting-off so readily as some others do. The cuttings of this will root freely if inserted singly in small pots filled with a light sandy-soil, and plunged in a propagating-frame having a gentle bottom-heat, and not much humidity. Another method of increasing stock is to surround the base of the stem with leaf-mould and sand, and the branches when rooted may then be detached, and potted in 60's in the same sort of soil; at the next shift making use of suitable loam, two-thirds decayed-manure, or half-decayed leaf-mould one-third, a small quantity of charcoal, and sharp sand. Primulas do best when stood on a bench covered with fine coal-ashes, or in a frame placed on the north-side of a wall; they should receive soot or manure diluted with rain-water at every fourth watering. The variety A. F. Barron has been very good with me this season, and will be extensively grown in the future for winter work; the flowers of this variety and those of The Marchioness of Exeter are very similar. A suitable temperature in which to winter double-flowered Primulas is one ranging from 50° to 55°. *H. Markham, Margate.*

PYRUS FLORIBUNDA.

The value of this species is being gradually recognised. The flowers are of a beautiful rosy-red colour, produced in great profusion before the leaves appear, succeeded later by small, roundish fruits. Its blossoms are scarcely, if ever, injured by spring frosts. The plant is better known as *Malus floribunda*, having been described in the *Revue Horticole* of 1881, p. 296, under that name. The plant appears to be a native of both China and Japan, and was introduced to Britain in 1818. *E. S., Woking.*

CYTISUS ARDOINI.

This rare dwarf Broom is now finishing its flowering, which begins about the middle of April. The only native habitat specified for it is Mount Aguglia, near Mentone, at an elevation of 4,000 feet. It was discovered there in 1847 by Ardoino, and named after him. It has been cultivated at Edge for more than twenty years on limestone rockeries, and some of the first plantings are now worn out, having spread to an area of several square yards, the plants now consisting of hard, and almost flowerless stalks a foot high. It roots so deeply amongst the stones that to clear it out they must all be removed, and the part rebuilt. It is well worth growing for the abundance of the golden flowers, and the early season at which it

produces them. Ten or twelve degrees of frost just when the flowers are opening, destroy them, so the situation should be warm and sheltered. Young shoots pulled up in autumn soon root in pots, and at three or four years old arrive at their most ornamental stage, when they are 2 or 3 feet square. It runs underground and under stones at a considerable depth, rooting as it runs. I have never known seed to ripen in my garden, but though the flowering is liable to be injured as mentioned already, the plant withstands the hardest English winters. It is said that the goats crop it so closely that it is rarely seen in flower on its native mountain. *C. Wolley Dod, Edge, Malpus.*

THE FERNERY.

HARDY FERNS.

(Continued from p. 163.)

IN connection with the Hart's-tongues, it is a great pity that a more extended use is not made of the very beautiful frilled or "crispum" varieties of the species, since well-grown specimens of these form extremely decorative and handsome foliage-plants. The true "crispums," being perfectly barren of spores, are somewhat rare, though they are easily enough raised from cuttings of the frond bases. Of late years some forms of this section have been raised with beautifully fimbriated edges to the frills, and well-developed tassels at the frond-tips, while the wild find known as *S. v. c. Drummondia* eclipses all the rest in its combined sports, since it is not merely frilled, fimbriated and tasselled, but has a waved mid-rib producing a sort of "switchback" in each frond; while, to cap the climax, the tips of the fimbriations run out into prothalli, and produce plants aposporously. This curious Fern, be it remarked, was found wild, and is not the outcome of selection and crossing, however much it may appear to be so from its complex character. Another "curio" in this species is *O'Kelly's cristatum*, of which the beautifully tasselled fronds have curious broad sagittate bases, and under congenial culture break out into a rash of youngsters on the upper surface.

Recurring to the work of the season, the sowing of spores reserved from the previous year may now be started advantageously, taking care to sow thinly, and to thoroughly sterilise the soil by previous saturation with boiling water. As a thimble-pot will accommodate hundreds of Ferns in their initial stage, the amateur may economise room to advantage by sowing in small pots or pans. Drain well, half fill with ordinary compost, and top with a little loam or crushed flower-pots; scald, allow to cool, and then sow very thinly on the surface; the spores must not be covered with soil. Insert a little label, and cover with glass, and in a week or two the crop of prothalli will begin to appear, to be followed later by the Ferns themselves *in propria persona*. For Polypodies sow on peat. Now, too, is the time for pricking out the youngsters resulting from last year's spore-culture. Crowding is never beneficial, and as all the growing season is now before us, elbow-room should be given betimes for proper development. It is, however, better to prick out into small pans at first, giving only an inch or so of room, rather than to pot off plants of too small a size individually. A very good plan is to prick seedlings round the edges of pots containing newly-shifted adult specimens. Although they will naturally have to be removed later, the active root-action of the old plants keeps the soil sweet, and helps the youngsters forward, with the minimum of subsequent care and attention. In this pricking-out process, a keen look-out should be kept for improved types. It is always possible that a batch of sporelings may contain something new; any of them, therefore, which differ markedly from the rest, should be delegated to a special pan for future observation. It is also highly advisable to keep a register of sowings, since the interest in the results is very much enhanced if the pedigree be known, while higgledy-piggledy operations can never in the long run yield results of same value as systematic ones. A "flake" may constitute an

agreeable surprise, but cannot possibly evoke the same satisfaction as a success, which has been skilfully aimed at and attained.

Finally, where the conditions are congenial for the growth of hardy Ferns, whether under a sheltering north wall, or a shady rockery, or in the conservatory, let the beautiful varieties have their due, and do not devote the space entirely to the common specific forms. These latter are beautiful enough in their way, but their place is in their native hedgebank, glen, or woodland nook, and emphatically not in the fernery proper. British Ferns, as bought by the bunch from the nurseryman or costermonger, or street-hawker generally, are no more the British Ferns of the connoisseur than the wild Roses of the hedges are the prize blooms of the rosarian. They are nothing more than Nature's raw material from which have been elaborated hundreds of far more beautiful types, frilled and tasselled, curled and feathered, and worthy of posts of honour in every collection of foliage plants. Kew Gardens can show a thousand-and-one gems culled as wild sports from our British woods, hills, and dales, and moorlands, or improved by subsequent selection, and yet out of a thousand so-called ferneries, nine hundred and ninety-nine will show naught but the common weeds, and not even a fair selection of those, since about half a dozen species out of forty odd, represent the range of "popular" British Ferns in a country which has eclipsed the world in its varietal Fern production. *Chas. T. Drury, F.L.S., V.M.H.*

CULTURAL MEMORANDA.

ERIOSTEMONS.

VARIOUS species of *Eriostemon* were once commonly cultivated in gardens, and being natives of New Holland, the plants as acclimated satisfactorily with other hard-wood greenhouse plants. Most of the species are of free growth, compact habit, and produce their flowers in great profusion over the period March to August. The soil in which *Eriostemons* thrive is one consisting of fibrous-peat $\frac{3}{4}$, silver-sand $\frac{1}{4}$, with a liberal quantity of crushed charcoal added; and the annual repotting may be performed early in the spring months. The flower-pots should be well drained, and have a few pieces of charcoal laid on the crocks in order to keep the drainage in a wholesome condition, for the plants require water copiously at the roots whilst in active growth, and to be well syringed till it is seen that the newly-potted subject has seized upon the new soil. The plants that are repotted should be placed in an intermediate-house until they make growth, and afterwards the greenhouse will be the best place for them.

It is immaterial in what form the plants are trained, though, for preference, I would recommend the pyramidal form, as this is easily attained by placing a neat stake in the centre of a plant, but not near the base of the stems, or the principal roots may get injured thereby. Let the leading shoot be secured to this stick, training it upwards as growth proceeds, the side growths being pinched in to induce uniformity of length. In the winter afford the plants a temperature of 40° to 45°, and avoid excess of humidity. Large, well-balanced specimens may be grown, provided the cultivator has strong, healthy plants to commence with, in about four years, if the hints I have given are attended to.

The species *E. buxifolius* and *E. cuspidatus* are of a more robust habit than *E. scabrum*, *E. myoporoides* and *E. pulchellus*, though all these are equally worthy of cultivation. Cuttings of the young shoots taken in April strike readily, if inserted in well-drained pots filled with sandy peat, covered with a bell-glass, and plunged in a mild bed of tan or leaves.

Grafting is usually resorted to by nurserymen, and the stocks used are *E. intermedia*, *E. nerifolia*, and *Correa alba*; the grafts will unite readily in about six weeks, and the month of September is the best time to graft. *H. T. M., Stoneleigh.*

RHODODENDRON KEWENSE ×

THE accompanying illustration (fig. 109) is from a photograph taken last May of a plant of this *Rhododendron* growing in the dell at Kew. It is a hybrid raised in 1875 in the temperate-house by the late Mr. W. Binder from *R. Griffithianum* (*R. Aucklandi* crossed with *R. Hookeri*); and a glance at woodcut will show that *R. Griffithianum* has had much the greater influence on the hybrid. The two, indeed, are in general appearance very similar. In a genus containing so many glorious plants as *Rhododendron* does, opinions would, no doubt, differ (were it necessary to decide) as to which species is the finest. For my part, I should give my vote to *R. Griffithianum*; and it is, I consider, in bringing so much of the beauty and distinction of that species into the open air that the great attractiveness and value of the Kew hybrid consist. *R. Griffithianum* is not hardy except in Cornwall and similar places, whereas plants of *R. kewense* × have been growing outside in the *Rhododendron*-dell at Kew for the last six or seven years. With a wood at the back, and large masses of *Rhododendron* around, this position is no doubt very sheltered, but the plants that have been out longest have had no artificial protection or covering. The foliage is very similar to that of *R. Aucklandi*, being smooth on both surfaces. The flowers are borne in loose trusses and vary in colour from almost pure white to a delicate rose. I have measured fully-expanded flowers that have been close on 5 inches across. The plant is at its greatest beauty when half the flowers are open, the other half still in bud. In all the forms (and there are several, although they have all come from the one sowing) the buds are rosy, and in some of the best are even a rich rosy-crimson, contrasting admirably with the paler hues of the fully open flowers. But the illustration gives a better idea of the beauty of *R. kewense* than any words can. In some respects it is the most beautiful *Rhododendron* hardy in the London district. It probably does not fulfil the florist's ideal of what a *Rhododendron* should be (I have heard the truss called "too floppy"), but then the florist's ideal of a plant, and the highest beauty it is capable of attaining, are two very different matters. *W. J. Bean.*

BELGIUM.

NOTES ON NURSERIES.

To say that the newly-established nursery, at Bruges, of Messrs. F. Sander & Co., is a wonderful establishment, whether considered in its vast extent, the elaborate, yet economical arrangement of every part of it, or the variety and excellent condition of the many beautiful plants cultivated in it, is but to mildly describe one of the largest horticultural ventures of modern times. Considering the short time which has passed since the site of the nursery was a bare piece of ground, the vast blocks of glass-houses filled with beautiful plants and flowers seem to have been evolved by magic. And so indeed they have, by that best form of magic—a clever preconceived plan, pushed on by an energetic proprietor with the necessary amount of capital at command, and with the assistance of a diligent staff.

Primarily, it may be said that the object of the nursery is of the same nature as that of all other Belgian establishments, viz., the production of large quantities of plants suitable for decorative purposes, and for cut-flowers, both out-doors and under glass, and also to attempt by the introduction of new plants suitable for the work, to give greater variety than is at present possible, and the lack of which creates such a strong resemblance of one market-establishment to another in the present day.

Orchids form a great feature in this nursery, and a large block of houses built of Pitch-pine, and each having its lobby arranged as a show-house, for the greater part filled with these plants. Each range has three divisions, and a walk through them disclosed thousands of *Cattleya labiata*, *C. Mossii*, *C. Mendeli*, *Miltonia vexillaria*, *Odontoglossum crispum*, *O. Pescay*,

toei, *O. cirrosum*, *Lælia anceps*, *L. purpurata*, *Lycaste Skinneri*, and other of the showy species, each of which contributed something to the display of flowers, to which additional interest is given by the presence of single specimens of many rare species. Among these we noted some remarkable hybrid *Odontoglossums*, notably two very distinct forms of *O. Andersonianum*, several grand varieties of *O. Wilckeanum*, the graceful *O. elegantius*, and a charming variety of *O. Humeum*, of a bright lemon-yellow colour, with purplish-brown markings on the sepals, and bright purple colouring on the upper side of the column, which caused it to form an unusually striking feature in the flower. Among pretty floral arrangements in the rockeries planted with foliage *Begonias*, at the ends of the houses, specially attractive were an

filled for the greater part with *Kentias* and other Palms and foliage plants in great variety, in all sizes, and in excellent condition, and most of the houses have the lobbies a blaze of colour given by the flowers of the *Azaleas*, which, with *Camellias*, are to form one of the specialties of the establishment. Something like one hundred plant-houses are already completed and filled, another large block in course of construction, and in the course of time probably the greater part of the outdoor nursery will be covered with glass.

A walk through the houses, disclosed house after house of *Kentias*, *Phoenix*, *Cocos Weddelliana*, and other Palms, for which there is a large demand, together with smaller batches of the rarer species and those requiring more heat than would warrant their

beauty. The raising of new varieties is also being undertaken with energy, and last year some 10,000 seedlings were raised. On the lines hitherto pursued in Belgium, it will be next to impossible to surpass the surprisingly beautiful varieties at present known—indeed, the difficulty of improving on the standard forms of years ago has been long experienced, but by the introduction of new elements in the crossing it is hoped to get a fresh race. *Camellias*, too, are being well and extensively grown, and the stock in all sizes seem in the most perfect condition.

In the open nursery were noticed a large stock of standards and pyramids, and planted-out Sweet Bays, large quantities of Lilies, and other flowers suitable for growing for cut flowers in large quantities. For convenience, and to facilitate orderly

[From a photograph by J. Gregory, Croydon.]

FIG. 109.—RHODODENDRON KEWENSE ×: COLOUR OF THE FLOWERS ROSE OR WHITE. (SEE P. 290.)

effective arrangement of *Cattleya Schroderae* and other species, a pretty group of *Odontoglossum cirrosum*, set up with varieties of the scarlet *Masdevallia ignea* and *M. caudata Shuttleworthi*; another of fine varieties of *Odontoglossum crispum*, with a few plants of *Cochlidia Noezliana*; a third was of *Lycaste Skinneri alba*, with some plants of the coloured *Lycastes*; another was of elegant sprays of *Oncidium sarcodes*, set up with scarlet *Anthuriums*; and each of the houses has some objects of special interest at the entrance-ends.

In one of the large warm houses, the collection of *Phalaenopsis* seem to be thriving, despite their removal from other quarters, which they often resent, and in an adjoining house a batch of *Vanda Sanderiana*, and the commencement of what is intended to be a large collection of *Nepenthes* are thriving well.

The remainder of the large block of houses is

being grown so extensively as the *Kentias*, and other hardier kinds. *Dracenas* also are largely grown, and conspicuous are *Dracæna Godseffiana*, the best for pots and for cut sprays of variegated foliage, as well as bearing fragrant flowers and forming a pretty scarlet-berried plant; and the white and green *D. Sanderiana*.

Coloured *Crotons* and *Bromeliads* figure in another part of the establishment; and a large stock of *Araucaria excelsa* is also grown. Among these is a small batch of a new variety of very distinct habit, and which arranges its branches in an ovate form instead of the angular manner of other varieties. The foliage also is softer and more curved than in other forms, the whole plant having an elegant Fern-like appearance. A large number of houses are devoted to the culture of *Azaleas*, and are filled with those charming flowers in plants of all sizes, from the one-year-old to the large specimen now in full

and expeditious carrying on of the work, the large packing-sheds, potting-sheds, and store-houses are excellently designed, and kept in as good condition as all the other parts of the vast establishment.

REMINISCENCES OF GHENT.

(Continued from p. 277.)

M. Metdepenningen's Orchids.—Son of the great lawyer Metdepenningen, Grand Bâtonnier de l'Ordre, whose statue adorns the garden in front of the Palais de Justice, and himself one of Ghent's most influential citizens, it is not a matter for surprise that M. Metdepenningen is a zealous cultivator of plants, as are so many of the citizens of Ghent. Within the limits of an ordinary town-garden in the Boulevard Zoologique, the owner has established a most satisfactory collection of Orchids, and at the time of our visit, in spite of the many fine

plants in flower taken to the great show, there was still a very good display of bloom; and what was better still, evidence in every house of the greatest vigour in the plants that reflected the utmost credit on M. Emil Arnaut the gardener. In the Odontoglossum-houses whose stages are edged with Tradescantias, some good species were in bloom, notably varieties of *O. crispum*, *O. triumphans*, *O. Pescatorei*, *O. Wilckeanum*, *O. Andersonianum*, *O. Halli*, *O. cirrhosum*, &c. Of the rarer kinds in bloom were *O. Schillerianum*, and a very richly tinted *O. Ruckerianum*, *Cochlioda Noezliana*, *Ada aurantiaca*, and some of the equally brilliant *Masdevallias*. The *Cattleyas* and *Laelias* were of surprising vigour; and in bloom were remarked *C. Mendeli*, and others, and some specimens of *Laelia purpurata* amply furnished with strong flower-sheaths. In one house was a good batch of the pretty *Oncidium microchilum*; in another a very fine stock of varieties of *Miltonia vexillaria*, and along with these last, *Cypripediums* were well represented.

In the greenhouses, *Roses*, *Cinerarias*, and *Begonias*, made a good display, and adjoining the commodious dwelling-house the lofty winter-garden was effective with grand specimen *Palms*, *Tree-ferns*, &c. reaching to the roof. At one end of this winter-garden a fountain plays over a high piece of rockery, and over which steps on either side lead to a balcony which forms a very pleasant retreat, and that too within a very few feet of the high road, the proximity of which there is little evidence, so quiet is it in this beautiful spot.

Mont St. Amand is a centre of the horticultural trade in Ghent, and it is not difficult to make calls at the various establishments—hurriedly, it must be admitted they were on this occasion. The first entered was that of M. K. J. Kuyk (the well-known establishment of M. Van Geert of former times), where a very fine display both of plants and flowers was discovered. The firm has another establishment at Haarlem, hence the great show of bulbous plants in the nurseries, and at the Quinquennial this year, where they were very successful. Outdoors there were great numbers of Sweet Bays to be seen growing in tubs, besides other plants suitable for similar decorative purposes. Foremost among these, so far as show was concerned, were handsome pyramidal *Cytisus* in full bloom; small *Orange bushes*, both in fruit and flower, were very effective; and in the various houses assigned to *Azalea indica* a most brilliant display was made. Then came house after house filled with *Kentias* and other *Palms*, with *Araucarias* of diverse species, *Anthuriums* with brilliant coloured spathes, and much besides.

M. Petrick has a very extensive nursery, which is kept in admirable order both indoors and out. As in most of the Belgian nurseries, a large proportion of the glasshouse is devoted to the culture of decorative plants, and especially such *Palms* as *Kentias*, *Phoenix*, *Latantias*, &c., and to *Dracæna excelsa*, the supply of which never seems to exceed the demand. An interesting feature in this nursery was the collection of rare stove and greenhouse plants, some or other of which are always in bloom, while the beautiful foliage of *Crotons* and *Dracænas*, so well cultivated here, afford effective contrast at all seasons. In the propagating-houses some useful lessons might be learned, for every operation is carried out in a neat and precise manner, which no doubt contributes largely to the success obtained in increasing the stock of plants difficult to propagate.

M. De Smet-Duvivier, in his nursery, makes a great feature of *Orchids*, new plants, and brilliant and delicately-coloured *Anthuriums*. His performances in the way of raising varieties of *A. Scherzerianum*, *A. Andreanum*, and other showy spathed *Anthuriums*, have resulted in a large number of pleasing crosses. The houses, which are connected by a corridor, are in many cases devoted to *Orchid* cultivation, and the first that was entered was a fine and well-cultivated collection of *Odontoglossums*, that afforded a really fine display of the best types of *O. crispum*, *O. triumphans*, *O. Pescatorei*, and others that flower in the spring. There were remarked some plants of *O. Oerstedii*, and of *Ada aurantiaca*.

In another house a good show of *Oncidium* species, with branched spikes 3 feet in length, was noticed, also of *Cattleya Schroderæ*, *C. Mendeli*, and a very fine variety of *C. Schilleriana*. On one side was a bank of *Miltonia vexillaria* of the finest large-flowered type; and in other houses good batches of most of the showy species of *Orchids*, some of them bearing flowers. The *Anthuriums* occupy more than one house, and a most brilliant display was made by their spathes, varying in colour from the rich dark scarlet of the best form of *A. Scherzerianum*, to light scarlet, rose colour, white, and white spotted with scarlet and salmon colour. Great advances have been made by M. de Smet-Duvivier in all the classes, and especially in the white-spathed kinds, with even the best of which he is still not satisfied, and is continuing to try to improve. One kind has twin spathes of scarlet colour, which is very striking. Continuing to glance at the contents of the numerous houses running from the corridor, we note several of mixed foliage plants of great beauty, one of the most striking being *Dracæna Cannæfolia variegata*. Then followed the many houses of *Palms*, &c., and the great six-span roofed structure filled with brilliant *Azaleas*.

In the corridor and in some of the houses we noted an excellent, clean, and durable arrangement for overhead shelves, consisting of a light framework of iron, on which was placed either common or thick glass, on which some moisture-holding material, such as Cocoa-nut fibre, was put on which to stand the plants. All who have experienced the perishable nature of wood shelves, and the harbour they make for insects when perishing, will be fully able to appreciate the benefits to be derived from such shelves.

M. Van Beerlere, at Mont St. Amand, has a new establishment devoted mainly to *Orchids*, and more especially to *Odontoglossums*, some 8,000 excellently-cultivated examples of which are to be found in his *Orchid-houses*, which seem admirably adapted to the culture of these plants, a fact which M. Van Beerlere mainly attributes to the fact that he has studied the requirements of the plants, and is his own architect, and directs the work of building, which is carried out by men employed by him personally. In the large house now in the course of construction, some interesting features in economical building was observed. The side walls had light angle-iron fastened to iron supports fixed to the wall, the angle-iron running along the top of the wall from end to end. Another light iron runs from end to end to form the ridge, and to these irons light wooden bars are cut in, the lower ends being fastened to the light iron which takes the place of a wall-plate, by bolts and nuts, and the ridge ends by screws. By keeping a stock of the iron-work necessary, and of wooden bars which will cut into any length, M. Van Beerlere says he can put up houses to suit himself and his plants at a moderate cost, and, what is of equal importance, in a very short time.

Some excellent varieties of *Odontoglossum crispum* and other *Odontoglossums* were in bloom, and also some good *Cypripediums* and other *Orchids*. In the stove-houses we noticed wonderful specimens of *Dracæna Goldieana*, *D. Lindenii*, *D. Massangeana*, and other coloured foliage plants. In the greenhouses fine *Azaleas*, *Araucarias*, &c., and in the lofty-house connecting the smaller houses some very fine *Palms* and other decorative plants.

MARKET GARDENING.

A NEW METHOD OF SPRAYING PLANTS IN HOUSES.

In the successful practice of market gardening, it is most important that every class of plants be afforded the exact conditions of cultivation necessary to bring them to perfection in as short a time as possible. Further, that the means of cultivation adopted should be the most economical that can be obtained.

We have observed from time to time the various ingenious contrivances made use of by market growers. The latest that has come before our notice

is one in use in the houses of Mr. Oakman, Scotland Green Farm, Ponders End, for the purpose of spraying *Cucumber-plants*. Mr. Oakman has nine houses containing *Cucumbers*, each being about 120 feet long and 11 feet wide. These are furnished with span-roof, and the glass comes down to within 18 inches of the ground. The *Cucumbers* are planted in mounds upon the ground, from end to end of either side.

At the present time when there is a good crop of *Cucumbers*, one can scarcely stand upright in the house, and in carrying a water-can for the purpose of spraying the plants with a syringe, or watering the roots, the workman would have to walk nearly doubled up. More than one market-grower, we assume, has found some difficulty in getting men who will thoroughly do the work under such disagreeable conditions—and little wonder. If the work be scamped, then the *Cucumber-plants* fail. Mr. Oakman, we believe, has been growing *Cucumbers* for something like thirty years, and these difficulties have been real ones to him. During the last season or two he has endeavoured to find a means of watering and syringing the plants with but little manual labour, and this he has now succeeded in doing, in a manner of which he is justly proud. He has fixed a leaden pipe along the roof-ridge in the centre of the house, and this is perforated on both its sides at distances of about 15 inches. When the tap is turned on, the very fine sprays from these perforations strike upwards to the glass, which breaks the water, and it descends upon the foliage as very fine rain, wetting it from the upper side and cooling the glass. Then about three quarters way down the roof on either side is fixed another leaden pipe, but in place of the fine perforations in the top one, these are provided with nozzles with roses about an inch-and-a-half across, at distances of 3 feet or thereabouts. These are screwed into the pipe upon one side only, but the whole pipe may be turned round readily by means of a wheel fixed near the taps in the centre of the house. Now if we proceed to this point in the middle of any one house we find two sets of brass taps, one set for one end of the house, the other for the end opposite. First we may turn on the pressure of water in the pipe at the summit, and immediately the very fine rain begins to rebound from the glass downwards. Then turn on other taps, and the pipes at the sides send forth very fine sprays from the roses; the wheel is turned, the pipes revolve, and the water is sent first up to the glass, then in the same upward angle as the trellis has, then down straight to the mounds where the roots are, and afterwards upon the leaves below the point at which the pipe is fixed. The house can be damped down without wetting the foliage, or the whole house may be syringed; and further, the borders may be given root-waterings without wetting the plants. It will thus be seen that the workman has simply to turn on the taps, and during the few minutes the moisture is descending upon one half of the house, he may stop or tie shoots in the other half, but the time necessary to spray the plants is very short. The system has two obvious advantages, that it saves much time or labour, and it does the work more thoroughly than a hand-syringe from underneath, and at the same time the spray is a much finer one. The side pipes are always left with the roses standing perpendicularly before the water-pressure is turned off, in order to keep the pipe full of water. The moment water is turned on the spraying commences along the whole length of the pipe, consequently there is no dribble, and the same quantity falls in every part. The contrivance is much preferred to hoses that are in use in some gardens, and indeed the best proof of its value may be seen in the excellent health of the *Cucumbers*.

During the last week in April, Mr. Oakman told us he had marketed 350 dozen fruits; on the following Monday nearly 100 dozen, and on Tuesday when we visited the houses there was still a good number of fruits upon the Vines. Any of our readers interested in the apparatus described above who may visit the establishment, Mr. Oakman will be pleased to give them every information concerning his patent. Cultivators may find that such a method might be

adopted in the case of many other plants that require an abundance of atmospheric moisture. Mr. Oakman grows some Tomatos, a large quantity of Ivy-leaved and other Pelargoniums and fruit trees, and various crops out-of-doors. P.

TRANSPLANTING VIOLETS AND MARGUERITES.

A favourable change having taken place in the weather for planting, no time should be lost in removing plants of Violets from their winter and early spring-flowering quarters, as glass-covered pits and frames, pulling them to pieces (so to speak), and transplanting the divisions in lightish, rich, free-working land, in rows 1 foot apart, and at the same distance from plant to plant in the row. In parting the old plants for replanting, select the strongest-crowned individual pieces for first planting, following these in rotation with the second and smallest-sized plants, shortening the few roots attached to each little plant in process of sorting, and dibble them into the ground at the distances indicated, making the soil moderately firm about the roots in doing so, affording water in the absence of heavy rain. When planting is completed, run the Dutch-hoe deeply between the lines of plants to loosen the ground, and so enable the roots to penetrate freely into the soil, repeating the operation a few times during the three following months, stimulating growth, and destroying weeds. Should the plants fail through lack of fertility in the soil to make free growth, a sprinkling of artificial manure round each plant before applying water will produce a beneficial effect. The object being to obtain large floriferous plants by the middle or end of August, and in view of this, the plants should be gone over once or twice during the summer, removing weak and superfluous runners, and pinching the points of those retained. Plants intended to remain in the ground for furnishing flowers in spring, should be planted in land sheltered on the north and east sides, and that is well drained. Hedges of Privet planted afford capital protection to these and other plants. Plan's for blooming in pits and frames during the autumn and winter should be taken up with soil attached towards the end of September, and planted therein, allowing them a space of a few inches every way, and keeping the foliage pretty close up to the glass without actually touching it, the soil of the beds being of the description recommended above. Marie Louise, having mauve lavender-blue flowers; De Parme, pale lavender-flowers; Wellsiana and Princess of Wales are most sought after by the public; especially is this the case with the first and last-mentioned varieties. Both Wellsiana and Princess of Wales produce large purple flowers, which are borne on foot-stalks from 1 to 9 inches long under good cultivation, the Princess of Wales sometimes attaining to as much as 12 inches in length.

Violets pay for generous treatment. Well-developed flowers of Marie Louise and Princess of Wales respectively, 1s. 6d. and 2s. per dozen bunches of twelve blooms, and well-grown plants of Marie Louise will each yield, I should say, at least 3½ dozen bunches during its entire flowering period, and the Princess of Wales 2½ dozen, thus representing about 5s. per plant. So that a pit 100 feet long and 6 feet wide would afford space for about 500 plants of the description indicated, the yield of which would represent £125 on the basis given above, and which I think within the mark.

The yellow Marguerite (Feu d'Or) is another good paying flower, realising (according to the flower market report published in the horticultural press) from 2s. to 4s. per dozen bunches of twelve flowers during the summer and early autumn months. The plant is not only a rapid grower, but also a profuse flowerer; the more you cut the flowers (always with long stems, mind), the more floriferous they grow. No time should be lost in transplanting the autumn-struck cuttings from cold frames and pits into ground of ordinary texture, depth, and fertility; setting the plants in rows 2 feet apart, and at the same distance from plant to plant in the rows, pressing the soil about the roots in planting, and afterwards affording water to settle the soil about the latter; repeating the application should dry weather prevail, until the roots have taken to the soil. H. W. Ward, Rayleigh.

FRENCH BEAN CANCKER.

(*Gloeosporium Lindemuthianum*, Sacc. & Magn.)

THIS destructive disease has been received from various parts during the past three years, and appears to be not uncommon in this country. It is most frequent on the pods of French Beans and Scarlet Runners, but also attacks the leaves and stem, and is by no means uncommon on the Beans themselves. On the pods, where it does most mischief, the fungus first appears as small, scattered, dark-coloured patches, surrounded by a reddish line. These spots gradually increase in size, and frequently

FIG. 110.—FRENCH BEAN CANCKER: *GLOEOSPORIUM LINDEMUTHIANUM*.

- 1, Fruit of Scarlet Runner, showing the disease; nat. size.
- 2, Section through portion of a diseased spot, showing the minute spores borne at the tips of slender threads or sporophores; also a long, dark-coloured spine growing up amongst the sporophores; $\times 400$.

grow into each other, forming large, irregularly-shaped blotches, having the dark central portion sunk below the level of the healthy portion. When the blotches are large and numerous, the pod is usually bent and deformed. When leaves are attacked, the veins are first blackened, the disease afterwards forming blackish blotches, which become dry and break away, forming holes in the leaf. Young portions of the stem and leaf-stalks are also attacked, and not unfrequently corroded to such an extent that parts above the wound die, and eventually fall off. Diseased seeds are pitted and blistered, and it has been clearly proved that if such are sown, the young plants resulting show the disease at a very

early age, and usually soon die, the fungus eating through the tender stem.

Soon after the depressed black patches are formed, their surface becomes studded with small pink granules, consisting of myriads of minute spores or reproductive bodies, held together by a viscid substance. These spores are readily set free by rain or dew, and washed on to healthy leaves or pods, where they quickly germinate, and form the starting-point of a new centre of disease, which in turn produces spores; consequently, when the disease once appears, its rapid spread is certain, unless stringent methods for its arrest are adopted.

If a very thin slice through a diseased spot is examined under the microscope, closely packed very slender threads will be seen, each bearing a single minute spore at its tip; mixed with these threads are scattered, long, dark-coloured, spine-like bodies. These brown spines, the use of which is unknown, are the only justification for establishing the genus *Colletotrichum*; in every other respect the species included in this genus are identical with the older genus *Gloeosporium*. It has been shown by Professor Halsted that, in the United States, *Gloeosporium lindemuthianum* is also parasitic on the rind of Cucumbers, Pumpkins, Water-melons, and Musk-melons.

Preventive Measures.—Spraying with dilute Bordeaux Mixture, if applied at an early stage, checks the spread of the disease; or, as a preventive measure, if the spraying is first applied when the seedlings are about three weeks old, prevents their being attacked, provided the seed was free from disease. Diseased plants should be removed the moment the fungus is observed, otherwise adjoining healthy plants soon become infected. If this simple means of prevention be consistently carried out, the disease would soon entirely disappear; whereas, if neglected, a spread of the pest is certain.

It is perfectly well known that diseased seed produces diseased plants; and, furthermore, the Beans may show so little external sign of the disease, that its presence might not be suspected. Hence, it is very important that seed obtained from a district where the disease existed, should not be sown. It may be accepted as certain that if seedling Beans show the disease, the disease existed in the seed. Geo. Massee.

NURSERY NOTES.

STANDARD BORONIA MEGASTIGMA.

THESE are a specialty at the Hassocks Nurseries, Sussex, of Messrs. W. Balchin & Sons. This style of plant is obtained by taking up a straight erect shoot to the height of 20 to 24 inches, stopping it, and thus inducing a break, which assumes the half-pendulous habit peculiar to the plant. But there seems to be a strain of this plant about which it is hardly desirable, of which specimens can be seen at the Hassocks Nurseries; the growth is rigid and upright as that of *Epacris*, while the flowers are small, and lacking in beauty. The desired form of this fragrant *Boronia* is of that free-branching, almost half-pendulous character, with flowers along the whole length of the shoots.

VIOLET PRINCESS OF WALES.

To realise the capabilities of this very fine variety, it should be seen at the Hassocks Nurseries. The plants put forth a bold and striking foliage, and produce flowers of large size, very fragrant, and borne on stout stems 9 to 12 inches in length. It is a Violet that should be planted out to be seen to the greatest advantage.

ACOKANTHERA SPECTABILIS.

This fine plant, better known as *Toxicophloea*, with its sweet and powerful perfume, is well named the Winter Sweet. Plants two years old from cuttings can be seen at the Hassocks Nurseries blooming with remarkable freedom, the long sprays of flowers formed of terminal and axillary corymbs. It is a plant of slow growth, flowering in a young state, and remaining for a considerable time in blossom. They appear to thrive under generous treatment, and the skill shown in making the best of this and kindred plants is witnessed at these nurseries.

PRIMULA VERTICILLATA SIMENSIS.

This is one of the most useful and showy species of Primulas for blooming at this season of the year—foliage and flowers alike are most attractive. A large batch of it is grown every year at the Hassocks Nurseries, and it finds a ready sale in Brighton for its sweet Cowslip fragrance, in addition to other desirable qualities. The plants are in 6 and 7-inch pots, they grow luxuriantly, and send up scapes bearing three or so whorls of yellow blossom. Plants are raised annually from seeds, and under proper treatment they soon attain to a good size, and two-year-old plants can be grown into superb specimens. Mr. W. Richardson, the manager at these nurseries, crossed this species with the common Polyanthus, and secured seeds, one of which germinated, but refused to grow much, and it is now a small plant, with about four leaves, which are of the Polyanthus type, and nothing seems to be capable of adding to its stature. As a matter of course, Mr. Richardson believes he has secured a cross, but its inability to make any progress is to him a matter of uncommon concern. R. D.

COLLINS & GABRIEL, HAMPTON.

Little more than a decade and a half since the name of Hampton, in so far as the market-growing industry is concerned, was scarcely known beyond its own small area. When Messrs. Collins came hither, the few market-nurseries could be counted on the fingers of one hand. Now there are, in Hampton alone—which is quite independent of Hampton Hill, Hampton Court, or Hampton Wick—upwards of seventy nurseries, either wholly or chiefly given up to growing plants, fruits, or flowers for London and provincial markets.

The nurseries of Messrs. Collins now cover something like a dozen acres, which is in great measure devoted to the culture of hardy plants and bulbs for the two-fold purpose of supplying the markets with bloom, and the wholesale and retail trade with the plants and roots. In these dozen acres there is scarcely a waste yard, the endless nursery beds being packed to overflowing with the choicest hardy plants and bulbs. In the former, large collections of Flag Irises, Pyrethrums, Phloxes, and such things as Michaelmas Daisies, and Sunflowers, are to be seen in great numbers. While the bulbous portion include all the leading kinds of Narcissi in their several sections and in great numbers, the variety Emperor, as indeed all such vigorous kinds, do splendidly in these nurseries; the great flag-like leaves are upwards of 2 feet high in a season unequalled for scarcity of rain; in more congenial seasons I have measured the foliage of this kind when upwards of 2½ feet high, and 1½ inch wide, which will give an idea of the health and vigour such things attain in suitable soil. The Bushy Daffodil has likewise been a feature here, perhaps the only place near London where this indispensable kind has been grown to such perfection. Nor is it merely Narcissi and Daffodils, all of which are grown by hundreds of thousands, but equally so of many bulbs, such as Liliums, Tulips, Gladiolus, and so forth. The former are a great feature here, as indeed are Tulips, which are forced in great numbers onwards from November each year. Among miscellaneous things of a tuberous-rooted nature are Alstroemerias, which are grown not in rows 18 inches apart, but *en masse* in beds 4 feet wide, and something like 100 feet in length. Pæonies cover several acres here, and the very choicest sorts are included. Delphiniums also are largely grown, and Christmas Roses, and an endless variety of hardy plants. An excellent strain of Polyanthus, noteworthy for size of flower and decisive colouring, was flowering grandly, the yellow, white, and orange shades being in many instances superb. As showing how the *multum in parvo* system is applied here, it should be stated that Apples and Plums are planted over some six acres at the edge of the pathways, thus virtually securing a crop that occupies but little actual space. Roses are also largely grown, chiefly Tea and H.P.'s. In the glasshouses are pink and red Roses of the H.P. class, largely, if not all, budded on the place. Bermuda Easter Lilies, Tea Roses, Gladiolus The Bride, and

Gardenias. There are large quantities of few species in the glass department. Several houses now contain Lilies. One long range is entirely given up to Gardenia, splendid vigorous bushes, some 4 feet high, and as much through, being crowded with fragrant flowers. The many houses now filled with Roses will presently find a new crop in the shape of Tomatos, already many thousands of which are potted in readiness, and Cucumbers, or such things, for the summer months. Then, with the advancing season for autumn and winter-blooming, Chrysanthemums are extensively grown. This is, indeed, a business of many branches, wherein the many intricate details are grasped and controlled with good judgment.

VARIORUM.

HOW TO SLING A HAMMOCK.—The ideal way to hang a hammock is to place it 6½ feet from the ground at the head, and 3¾ feet at the foot. The rope that secures the head should measure about 1 foot—it is better to be less—and at the foot about five times that. The object of this is to keep the head comfortable by being nearly stationary, while the lower part of the hammock will swing freely. *Canadian Horticulturist.*

THE WEEK'S WORK.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Early Vines.—It will now be necessary in the warmer parts of the country, and especially on light loams, to make an investigation of the borders outside the vineries, as these will be getting in need of moisture owing to a deficient rainfall. If any part of the soil be found in a dryish condition, water should be afforded in quantities sufficient to penetrate to the drainage, and pass out of the main drain. If a part of a border is moist whilst another is dry, there is almost sure to be something wrong with the drainage of that part, and a note should be made of the fact for future rectification. If an inside border has to be afforded water, it should be made tepid before applying it; but for an outside one, river, pond, or water from an open-air basin is suitable. Spring or well-water should not be used without first exposing it to the air for several days. Liquid-manure may be added to the water used if a stimulus to growth is believed to be necessary. In place of liquid-manure, fish-manure, and bone-meal, may be strewn on the surface previously to applying water. An outside Vine-border should be stirred with the hoe frequently, so as to allow the air and sun's warmth to penetrate the soil, and to prevent excessive evaporation, hence it is unwise to trample on a Vine-border or to grow plants of any kind upon it. A crumbling surface is as good as a mulch, without having the disadvantages of the latter.

Planting Vines.—The Vines struck from eyes this year should be afforded as long season of growth as possible, and preparations should be commenced for planting them in the borders now that the fruit is ripe on the canes that are going to be rooted out. The work need not be delayed till the Grapes are consumed, but the remaining portion of the crop may be cut and bottled, and the work of border-making begun. After grubbing up the worn-out Vines, wash the wood-work and white-wash the walls to about 6 inches below the ground level. Then excavate a portion of the old border at the front 4 feet in width, together with the drainage materials the entire length of the vinery, which will afford sufficient space for the roots of the young Vines for one year. It will be well to make an inside border, and let this get filled with roots before allowing the roots to grow outside. To prevent this the arches may be filled up temporarily with bricks, having a coat of plaster on the inner side. The roots should be quite under the control of the cultivator, and to this end the border should have a bottom of concrete. If a border is not concreted, the renewed portion may be concreted at this season, and the remainder of the area inside and outside at such times as additions are made to the border. The total depth of a border need not exceed 3 feet 6 inches. As soils for making a border, use sods cut from an old pasture from 4 to 6 inches thick, plaster or lime-rubbish one-eighth, charred

soil one-eighth, and bone-meal 1 quart to each wheelbarrow-load of the soil, chopping it all up but little or not at all, but laying the sods regularly, scattering the other ingredients between the layers, and making these very firm, and carrying it about 6 inches higher than the required height. When all is ready, throw out a shallow wide trench next to the front wall, spread out the roots a little, affording a space of 3 to 3½ feet from one Vine to the next, and shade and keep close till they begin to grow, then treat them the same as growing Vines. Let the main cane grow without stopping till it reaches the back-wall, if it be a lean-to house, and then let it extend down the back wall unchecked, the main object being to encourage by unchecked top-growth the extension of the roots in the border. If the Vines are likely to become pot-bound in the 8-inch pots they are now in, before it is convenient to plant them, shift them into 11-inch pots. The best black variety for producing early Grapes is Black Hamburgh, and the best white, Foster's Seedling.

Tomatos.—Let all bare spaces on the trellises in late Peach-houses be filled with strong Tomato-plants—the fruit is sure to be acceptable; and let some of the plants have clusters of fruit already set. In the course of a few weeks, a top-dressing of soil and manure will be required, but not at the first, and much water should not be afforded. Plants in bloom should not be stimulated with either new soil or manure. Plants that have filled their allotted space should be stopped by nipping out the leading point or points; let lateral shoots be removed, and curtail the leaves if crowding is feared.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

What to Sow.—Seeds of *Primula sinensis* and of the hybrid (florist's) *Cinerarias* may be sown for the main batches in well-drained seed-pans or boxes, these being prepared in the manner advised in a former calendar. As *Primula* seed generally germinates slowly, place the pans, &c. in a frame in a moderately cool position, covering them with sheets of glass, over which put moss or brown-paper to prevent the sun reaching them, as affording water before the seedlings appear is almost certain to kill the seeds. *Cineraria* seed may be similarly treated. A small quantity of seed of *Celosia plumosa* may also be sown in warmth, a late batch of this highly ornamental plant being usually of great use in the conservatory late in the summer. *Panicum altissimum* seed, if sown forthwith, and the plants grown in heat for a time, makes useful stuff by the arrival of the autumn. Sow in pans filled with a light sandy mixture, and when the plants are large enough to be handled readily, pot them into thumbs, and repot as the plants increase in size till they come into 48's; this species of grass has a light and elegant appearance with other plants, and is excellent for associating with others. If an early batch of *Calceolaria hybrida* is wished for, a pinch of seed may now be sown in rich soil made firm; and as the seed is extremely small, care must be taken to distribute it evenly on the surface of the soil. Place the pot or pan in a moist, shaded position in the greenhouse or vinery, and in about one month the young plants will be ready for placing in thumb-pots. Shade and moisture are essential to this plant, and especially after each repotting. It is not too late to sow a small quantity of *Balsam* seed should the earlier batch have turned out unsatisfactorily.

Table and Vase Plants.—Plants of *Panicum variegatum* that are established and in active growth, may have the points taken off closely, sticking these in around the base of the other plants, and these will soon cover the tops of the pots, and form a pleasing contrast in the case of *Dracenas* and other plants with dark-coloured foliage. It is a means of doing away with the use of wood-moss for covering the pots, and is neater and more ornamental.

Achimenes.—The plants if growing freely may be shifted into flower-pots of a larger size, and stakes afforded as the shoots lengthen. If grown in pots it is best not to allow the shoots to fall about in a careless manner, or the stronger ones will smother and spoil the weaker. Let these plants be shaded from sunshine or they will soon spoil. *Achimenes* growing in baskets should have the shoots tied in somewhat, but sticks will scarcely be needed. Afford a further shift to tuberous-rooted *Begonias* which have filled their pots with roots; gradually harden off *Spiræas*, *Azalea mollis*, *Lilacs*, *Rhododendrons*, &c., that have been forced, finishing the hardening off in cold pits or frames before standing them out of doors.

HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Strawberries for Fruiting in the Autumn.—Any healthy forced plants of Vicomtesse Héricart du Thury, La Grosse Sucrée, John Ruskin, or others which have ceased to bear, will give another crop of fruit in the autumn if they are properly treated from now onwards. The plants should be cleared of all the fruit-stems and decaying leaves, and the soil afforded clear water copiously, and if any red-spider infest the foliage, the crowns should be dipped in suds made with Gishurst Compound-soap at the rate of 4 oz. to 1 gallon of rain-water, not rinsing off the suds, but shading the plants from bright sunshine for a few days in a cold pit. The plants may be afforded air in abundance at all times, the lights being pulled off in dull weather, and allowed to remain off on mild nights. In the meantime, a plot of ground should be got in readiness for them by digging and manuring, and as fruit will be ripening when the sun's power is declining, the plot must be selected where sunshine reaches it all day long. If farmyard manure be not available, a good dressing of phosphatic manure may be afforded instead, applying it after the plants are established. The soil should be dug deeply, and the clods broken up with the spade, otherwise the plants will be liable to suffer during dry weather. Before planting, place the plants for a few minutes in water, so as to thoroughly moisten the soil; the doing of this saving much trouble, it not being an easy matter to soak a dry mass of soil and roots after it is planted, and if the soil gets thoroughly dry, the plant is sure to fail. Remove all the runners and the crocks before planting, but do not break up the ball, and let the soil be made firm around each plant by ramming. The rows of Vicomtesse H. du Thury and John Ruskin should be $2\frac{1}{2}$ feet, and the plants 2 feet apart in the rows. La Grosse Sucrée being a less vigorous grower may be planted at 6 inches closer each way. As soon as planting is finished, mulch with stable-litter or half-decayed manure, and in dry weather afford water occasionally until the plants are established; afterwards very little attention is needed till the fruit turns in in September, with the exception of removing all flower-stalks till the first week in August, and all runners from the plants and weeds from the soil. The three varieties named are the only ones which I have found satisfactory in the autumn, and the plants bear good crops the following summer.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorset.

Cymbidiums.—*C. eburneum*, *C. Traceyanum*, *C. affine*, *C. canaliculatum*, *C. Mastersii*, *C. elegans*, *C. aloifolium*, *C. chloranthum*, *C. longifolium*, *C. Lowio-eburneum*, and the reverse cross *C. eburneo-Lowianum*, thrive well in a cool part of the intermediate-house if the plants be shaded from the sun. The plants may be repotted as they pass out of flower. Having thick fleshy roots, they require extra sized well-drained pots. Use a compost consisting of one half turfy loam, the other half peat and sphagnum-moss, to which may be added a little leaf-soil and crocks in sufficient quantities to keep the soil porous. Press the compost with moderate firmness, and instead of elevating the plants above the rim of the pot, keep the soil at least half an-inch below it. *C. Lowianum*, *C. Hookerianum*, *C. giganteum*, and *C. pendulum* do not require so much pot-room as recommended for the other species. When properly potted and cared for, they may remain undisturbed for several years, producing flower-spikes more freely when in a pot-bound condition. *C. Devonianum* has just bloomed, and may be repotted if necessary. These *Cymbidiums* require plenty of water during the growing season, and when well rooted in the compost they grow fast and bloom freely, the leaves retaining their tips fresh and green.

Phalaenopsis.—The species belonging to this genus when well bloomed are among the most beautiful of Orchids. Such species as *P. Schilleriana*, *P. amabilis*, *P. Aphrodite (grandiflora)*, *P. Sanderiana*, *P. intermedia*, *Portei*, and *P. Esmeralda*, have in many collections now passed out of flower, and in various ways the plants show signs of activity. Those plants that require more root-room should be afforded the same at once, or if the potting materials be worn out or likely soon to decay, this should be renewed. In some cases the old sphagnum-moss will have grown so luxuriantly that when watered it remains wet for too long a period, and will, therefore, need to be replaced with new. Previous to overhauling the plants, the old moss should be allowed to become somewhat dry, as it is

more easily removed than if wet. *Phalaenopsis* should not be disturbed by rebasketing oftener than is absolutely necessary, as their roots are very susceptible to injury. After taking out the moss and drainage materials, it is a good plan to immerse the basket for a few minutes in a tub filled with water, when with a thin bladed knife the roots can easily be detached. Teak-wood baskets of suitable sizes should be selected that will last for several seasons, using new baskets in preference to old, the young roots attaching themselves more readily to new wood. Place the plant in the centre of the basket, and spread the roots out as near to the sides as is possible, then fill up to three parts of its depth with clean crocks, keeping the collar of the plant raised above the top bar, and surface the drainage with good sphagnum-moss and crocks in equal proportions, pressing these moderately firm; then place a layer of moss over the whole so as to form a round cone over the roots of the plant. Place the plants in a shady position on the north or west side of the East Indian-house or plant-stove. They will succeed if suspended near the glass, or stood upon suitable stands down on the side stages. When suspended from the roof they are safer from slugs and cockroaches, such dangerous foes to the young roots of these plants. After rebasketing very little water will be necessary, and for a time merely sprinkling the moss on the surface to keep it fresh and green will suffice. Freshly-imported plants generally arrive on long blocks of wood, or on a bit of the branch on which they grew. Any that arrive at this season may be removed at once from the blocks, &c., and put into baskets, but any that arrive during the autumn should not be so treated until the following spring.

The Dove Orchid (Peristeria elata) grows freely on the shady side of the warmest house; and it is now commencing to push out new roots, which is the right time to surface the compost with sphagnum-moss, into which the young roots delight to penetrate. The plant now requires a liberal supply of water until the new pseudo-bulbs are made up. When the new growths commence to form their bulbs, the plant should be gradually inured to extra light, so that by the time the latter are completed they will have become accustomed to full sunshine.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

New Zealand Spinach.—This vegetable, *Tetragonia expansa*, has much to recommend it in hot and dry soils as a substitute for common Spinach, it being less apt to run to seed. The seed should now be sown in drills $2\frac{1}{2}$ feet apart, and $\frac{1}{2}$ inch deep, in the open ground, and the seedlings thinned out at an early date to a distance of 18 inches apart in the rows. Much ground need not be put under this crop.

Vegetable Marrows.—All the forwardest plants may now be planted in rich soil, and covered with frames or handlights. The plant being tender, cold must be guarded against by covering the frames, &c., till the end of the month. If a mild bottom-heat can be afforded, it will add vigour to the plants at the first.

Asparagus should now be in full growth, and all heads that are fit should be gathered daily. Let these be tied up into bundles after sorting them into different sizes, and place them butt-end downwards in damp soil or sand, or saucers containing water, and keep in a dark place. Afford a dressing of agricultural salt to the beds at the rate of 2 oz. to the square yard, doing this in showery weather.

Kidney Beans.—Large sowings may be safely made of such varieties as Canadian Wonder, Negro Long-Pod, Ne Plus Ultra, and of the climbing Tender and True. This last-named plant grows to 6 feet in height, and produces abundance of long rather narrow Beans of fine quality, and the seed should be sown thinly in rows 5 to 6 feet asunder, whilst Canadian Wonder (Red Flageolet) may have 3 feet, and the others named $1\frac{1}{2}$ to 2 feet spaces.

Rhubarb.—If flower-stems show, cut them off low down; and if the plantation is aged afford it, in rainy weather, a dressing of bone-meal and guano, and pull the stalks for use, a few from each plant, so long as they are tender.

Destroying Slugs.—These are a great plague in some gardens, eating off seedling plants and doing other damage. The most effectual method of destroying them is hand-picking in showery weather, and dust the plants that are mostly eaten by the creatures with freshly-slaked lime late in the evening; also setting baits of bran, Cabbage-leaves, and of slates and tiles elevated about half an inch from the ground.

Potatoes.—Hoe the ground between the lines, and draw a small quantity of earth up to those stems that have pushed through it.

Hoeing and Weeding.—There is no work in the kitchen garden which at this time requires closer attention than the destruction of weeds before they seed, and the hoe should be kept going whenever the state of the soil will permit.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

The Flowering Shrubs of Spring and Early Summer.—At the present time there exists to those whose delight and chief hobby is to plant hardy-flowering deciduous shrubs in the garden and pleasure-grounds of country residences, a great treat at this season. In English gardens nothing can excel the beauties of such shrubs, especially when these have arrived at mature age, or they are planted in masses; the colours of the flowers, the different tints of the foliage, and sometimes the fragrance emitted being so charming. It must suffice, however, merely to give the names of a few, as for example the double-flowered Gorse, the graceful Broom, Ribes or flowering Currants, in variety; Berberis Darwinii, with its graceful yellow inflorescence, effective as isolated plants or as groups—and excellent as a garden-hedge plant, flowering abundantly in such position if not clipped too closely. The bright-yellow flowered Kerria japonica, either single or double flowered, is a capital shrub, or it may be trained on a wall; the many varieties of Cerasus, or Cherry, of which *C. japonica* albo flore-pleno and *C. Juliana* folius variegatus are fine; and especially fine is *C. Wateri*, a beautiful dense-flowering variety, with pink blossoms. In direct contrast to these, as regards form and colour, are the bright flowers of Cydonia japonica, *C. Maulei*, and others; the yellow-flowered Forsythia viridissima; Staphylea colchica, Wistaria sinensis; the chaste Amelanchiers, and the snow-white Deutzias, crenata, and gracilis. All of these, and many others, are at the present time in flower, and they will be succeeded by Laburnum and others—Cytisus, Lilacs, Clematis vitalba, *C. montana*, *C. viorna*, and hybrids. Of shrubs with ornamental foliage, there are gold and silver forms of the common Elder, with variously-formed leaves; the Sea Buckthorn, whose leaves are grey-green; Euonymus radicans folius variegatus, Aucuba, Ilex in many varieties, Osmanthus illicifolius, *O. myrtifolius* and the variegated forms of the first-named, Eucryphia pinnatifolia, Berberis. In the milder parts of the country the fine New Zealand and Japanese species of shrubs might be planted, and for a list of these reference might be made to p. 684 of the *Gardeners' Chronicle* for December 5, 1896.

Creepers.—As these plants grow rapidly at this season, no time should be lost in thinning-out the weak, flowerless shoots, and nailing-in sufficient good wood to cover the allotted space. In the treatment of climbing plants of whatever species, crowding the growths should, as a rule, be avoided, or the desired effects will be spoiled, particularly is this applicable to the climbing Clematises, Bignonia radicans, Loniceras, Vitis Coignetiae, Roses, and Wistaria sinensis. If the soil of the borders in which climbers are grown is in a dry state, which is almost always the case if these skirt a high wall or a building, water should be afforded freely from time to time, otherwise progress will be slow and unsatisfactory. Where Ivy covered walls exist, the present is the proper season for clipping the Ivy close to the wall, and cleaning out the accumulated rubbish. New leaves soon develop, which afford a bright green tint in place of the dull green of the old foliage.

General Remarks.—The recent rains have been grateful to all kinds of vegetation, and growth is going on with rapidity; equally so is that of the weeds, and the latter, when the ground is sufficiently dry should be pulled up, or the ground hoed on a dry, sunny day. Continue to plant out from time to time all kinds of bedding and border plants, excepting those that are tender; and prepare for the chief bedding-out, which may soon be undertaken in the south.

EXTRAORDINARY RATING OF GLASS-HOUSES.

—The *West Middlesex Times* reports in its issue of April 30, that Messrs. CORNICK & HEARD, nurserymen, of Ashford, Middlesex, on Tuesday last appeared before the Assessment Committee of the Staines District Council to appeal against the high assessment of glass houses, but without redress, and were told their glass would be measured and assessed at the rate of £100 per acre.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	MAY 16	{ Devon County Agricultural Show at Newton Abbot.
WEDNESDAY,	MAY 18	{ Ancient Society of York Florists' Exhibition.
FRIDAY,	MAY 20	—Royal Botanic Society, Lecture.

SALES.

MONDAY,	MAY 16	{ Japanese Lilies, Tree Ferns, Palms, Greenhouse Plants, Gladioli, &c., at Protheroe & Morris' Rooms.
TUESDAY,	MAY 17	{ Sale of the Surbiton Nurseries, Ewell Road, Surbiton; also, Lease of old House and Shop, together with the Plants, Horse, and Utensils in Trade, on the Premises, by Protheroe & Morris' (two days).
FRIDAY,	MAY 20	{ Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—55° 1°.

ACTUAL TEMPERATURES:—

LONDON.—May 11 (6 P.M.): Max., 58°; Min., 50°.

PROVINCES.—May 11 (6 P.M.): Max., 56°, S. Devon; Min., 44°, Aberdeen.

Rain, dull, mild.

THE exhibits of Radishes from the Chiswick Gardens of the Royal Horticultural Society, on Tuesday last, reminds us that in a recent number of the *Revue Horticole* M. H. DE VILMORIN speaks of small, early Radishes, known and widely appreciated, especially on the Continent, under the name of "Tous les mois." The Radish, as supplied by the average English greengrocer, is but too often old, tough, hot, and stale; but there is no reason why, with a little care, we should not always see this dainty vegetable fresh, crisp, and young.

M. DE VILMORIN speaks of the wide diffusion of Radishes; how they are to be seen daily in the markets of the principal towns and cities all over the world wherever Europeans congregate. In hotels, large and small, restaurants, railway-buffets and inns, Radishes are always to be had. In African and other campaigns, wherever troops are likely to be quartered in one locality for several months, one of the first occupations of the officers is to establish gardens where, among other seeds, Radishes are sown, and, three weeks after the date of sowing, are ready for eating.

During the long winter-exile of whalers or explorers, boxes stored in the boats, often with earth especially brought for the purpose, are planted, whenever a little daylight will allow of the growth of vegetation, with Cress, Cochlearia, and Radishes in a warmed place, green-meat being the best preventive of the diseases of a cold climate, especially of scurvy.

M. DE VILMORIN illustrates his article with a coloured plate, showing a most tempting assortment of Radishes, to the varieties of form and colouring of which he draws attention. The reason for this diversity is to be sought in the fact that many different tastes have to be considered; also the seasons of the year and methods of cultivation necessitate the sowing now of one, now of another kind. The importance of early varieties is obvious if it is considered that to be two or three days in advance is to ensure three crops instead of four from the same beds made up for winter forcing; and to receive the payment for many dishes of Radishes some few days sooner.

In kitchen, as in market-gardening, time is money; and variety, always sought after, is obtained by sowing seed of kinds of varying forms of colour and degrees of precocity, according to custom and local preference.

Further than this, we may divide Radishes suited for private cultivation from the market-garden varieties. These latter must yield quickly, be of uniform quality, of good appearance, which can be at once put on the market, leaving the ground free for another crop, or for a second sowing of the same vegetable. It matters little if these market varieties have a tendency to become flabby when past their prime, as they are always drawn, bunched, and sold, before this can happen.

In private gardens the gardener sows, like the wholesale grower, very frequently. He will plant a quarter of the bed at a time, and expect to cull daily 100 Radishes for at least eight or ten days; therefore, he might choose a variety of rather slower growth maybe, but firmer, and not apt to get weak and flabby. In daily selecting the largest roots he leaves room for the others, and for some time obtains, without further labour, a continuous and uniform yield. Among these comparatively hardy outdoor Radishes there must be, to satisfy different tastes, round and long shapes and diversely-coloured roots, so this gives rise to the introduction of many market-garden and other sorts, there being more than twenty varieties quite distinct, and generally characterised by some descriptive name.

The origin of the cultivated Radish is not exactly known. A hypothesis often offered, notably by M. E. A. CARRIÈRE, that the plant is derived from *Raphanus raphanistrum*, can hardly be successfully maintained. Two serious objections may be raised: firstly, the jointed pod in *R. raphanistrum* and the pod without partitions in cultivated Radishes; secondly, the always white or pinkish flower of the latter, while in the wild plant the bloom is often yellow. Judging by a physiological characteristic, as the cultivated Radishes resist cold less well than the wild variety, we may infer that the former has a more southerly origin.

The analogy in the structure of the leaves, of the pods, and in the appearance of the seed, gives some colour to the idea that cultivated Radishes, as well as the oil-bearing variety of Madras, and the Mougri de Java or serpent Radish, are derived from an Indian species now perhaps extinct.

Whatever may have been the origin of the annual Radish, there is ground for supposing that the root was at first red or violet, as these colours are still the most predominant; the white and yellow forms might be derived from either of these colours.

Until the beginning of the present century, the round, red, and white Radishes, with some

very long kinds, were almost the only varieties in use. These sorts are comparatively leafy, develop rather slowly, but have the compensating advantage of keeping crisp longer.

In the same category a rather recent race may be included: the round *sang de bœuf* Radish, intensely red, with firm crisp flesh, growing well in ordinary soil, and during the summer months.

With this may be classed the extra-early round yellow Radish. As regards use and cultural requirements, these sorts are akin to the semi-long red, white, and scarlet Radishes. All these three develop in a month, but keep well; the two former are olive-shaped, the latter longer and more pointed than are the early semi-long scarlet Radishes. All the above varieties M. VILMORIN classes together as the old or original forms.

Another range, which may be called modern, includes earlier, better and choicer sorts, which are, however, more exacting as to soil and attention. These very tender and delicate Radishes like good soil, and require frequent watering. They are as well suited for market-gardens as for private grounds if well looked after, and are in every way the best and most widely known.

Among the round varieties of this class, the Early Round Rose, the Round Rose, with a white tip, are admirable for colouring, rapid growth, and tenderness; even if as large as a small Walnut, the little Early Round White, which is slightly flattened, has very delicate flesh and small foliage, often brown in the centre; the Round Early Scarlet is peculiar for its roundness and bright colouring; the Round Early Violet and its variety, with a white tip, are equally good, and introduce an acceptable diversity in colouring. Semi-long sorts are rather less numerous, and may be reduced to four, or perhaps five, kinds, as one series is subdivided to distinguish the semi-long Rose White-tipped Radish. In fact, horticulturists trace two distinct origins: Radishes from the one are clear rose-coloured, and of an elongated olive form—these are of the Southern race; others, rounder and deeper red in colour, belong to the "Chevreuse" kind, and are those most commonly seen in France. The very long shape is not peculiar to these species, but is in a way the result of a method of cultivation of which the Parisian market-growers know the secret. The semi-long, scarlet, white-tipped Radishes are also very popular, and notable for brilliancy of colouring. The semi-long early-scarlet has an olive-shaped root, coloured down to the tip, and is probably the most scarlet of all Radishes; it is very early and attractive in appearance. Then there is the semi-long, violet, white-tipped Radish, very pretty and charming, and only needing to be more widely known to be generally used.

The last series, which may be called that of *fin de siècle* Radishes, takes the first place for earliness. It includes extra-early varieties with small foliage, just sufficient to nourish the roots and to enable them to be bunched, an important economic consideration. In some of these forcing varieties, the root is ready when the second leaf after the cotyledons or seed-leaves is not fully developed. Under favourable circumstances these extra-early Radishes are ready about a fortnight after sowing. Among these sorts, valuable for forcing, or even for open-air cultivation in suitable seasons, are included the round Rose forcing Radish, the round Rose white-tipped forcing Radish, the round Scarlet white-tipped forcing Radish, and

FIG. 111.—VIEW IN THE GROUNDS, CARNE, PENZANCE, THE RESIDENCE OF F. ST. JOHN TUPPER ESQ., WITH ST. MICHAEL'S MOUNT IN THE DISTANCE. (SEE P. 29.)

Engraving by R. H. Preston, F.R.S.

the round early Scarlet. Long-rooted kinds are the semi-long White forcing, olive-shaped with small foliage; semi-long White, tipped rose; and semi-long white-tipped Scarlet, which are varieties of the sorts in the second category, but of more rapid growth and with less foliage.

Then there is the uncommon sort, not to be exactly classed with any of the others, the Leafless Red, forcing Radish. This is a great curiosity, with but one leaf, wrinkled, and between the two well-developed and persistent cotyledons. The root is slightly elongated, or nearly spherical, and attains an average size. The round Scarlet and the forcing semi-long Scarlet yield as rapidly and surely a crop equivalent in appearance and quality.

We have quoted this long description, although our readers would the better understand it had they reference to the pretty plate in the *Revue Horticole*, or had they seen the collection that was brought from Chiswick. In any case, they will gather from what has been said, that among these early Radishes there is sufficient variety to please all tastes; that the distinctions between them are not great; the methods of cultivating them differ little, except that there are modifications for the market-gardener who grows on a large scale, and for the private grower. For the latter, all the varieties named are available; and if, instead of planting one kind only, he will vary them, he will obtain an agreeable diversity, not merely of shapes and colouring, but of flavour, which it will be additional interest to comment upon, and to compare one with another. As it is, it cannot be said that our Radishes, as generally met with, compare at all favourably with those we see in France.

ROYAL HORTICULTURAL SOCIETY: THE TEMPLE SHOW, MAY 25, 26, AND 27.—For the eleventh year in succession, the Royal Horticultural Society will hold their great annual flower-show in the Inner Temple Gardens on May 25, 26, and 27. Every year the desire of growers to exhibit increases, and the officials of the Society have a very anxious task in endeavouring to do justice to those growers who support the fortnightly shows of the Society held at the Drill Hall, and yet at the same time to encourage others also to come forward. The space is absolutely limited by agreement with the Temple authorities, and no more or larger tents may be erected. Hence, every new exhibitor whose entry is accepted, means curtailment of the space allotted to previous supporters. A catalogue of the show will be given gratis to every visitor, and will contain a notice of new and rare plants entered on or before May 19. It will also contain a programme of the music to be performed each day. On the first two days the band of H.M.'s 2nd Life Guards, and on the 3rd day the band of H.M.'s Royal Horse Guards will perform. The judges will meet at the Secretary's tent at 10.30 A.M., on May 25, at which hour punctually the tents will be cleared of all exhibitors and their assistants. The Fruit, Floral, and Orchid Committees will assemble at the Secretary's tent at 11 A.M. sharp, and the show will be opened at 12.30 P.M. All plants for Certificates must be entered on or before Monday, May 23. Address: Secretary, Royal Horticultural Society, 117, Victoria Street, S.W. They cannot be entered under any circumstances on the day of the show.

A correspondent, residing near Preston, sends the following: "Members of the Preston and Fulwood Horticultural Society are forming a party to visit London during the show week. Mr. FRAME, of Fishergate, Preston, the courteous tourist's conductor, has charge of the arrangements, and will conduct parties wishing to see the sights of London. The train starts on Tuesday night, May 24, leaving Windermere at 9 o'clock, Kendal 9.18, Oxenholme

9.27, Carnforth 9.55, Lancaster 10.7, and Preston 11.51. There will also be trains on the branch lines from the Fylde district to Preston. It is expected that a number of gardeners from Liverpool will join the train at Wigan, who will be accommodated with saloon carriages if timely application be made. Further information may be had from Mr. FRAME or Mr. C. PARKER, secretary of the Preston and Fulwood Horticultural Society, 11, Cannon Street, Preston.

"KEW BULLETIN."—No. 132, December, 1897, has just been issued. Its contents are of unusual interest, comprising extracts from letters of Dr. HENRY from Yunnan, in which he urges the despatch of a botanist to Szechwan and the neighbourhood. The flora is very rich, extremely interesting, and contains many plants which would be suitable for introduction here. Perhaps the Royal Horticultural Society, having fallen on better days, might be induced to assist, and renew its old glories. The introduction of *Ficus elastica* into Egypt promises to be a matter of importance as a source of rubber. The great demand for the timber of white Willow—for cricket-bats!—will give rise to much thought on the part of practical men, as well as of philosophers! The fate of the pelican is detailed, but the conduct of the gamekeeper was so abominable, that it is to be hoped he will be deprived of his gun forthwith.

ROSE FIXTURES IN 1898.—The following additional fixtures occur during June and July:—June 16 (Thursday), Isle of Wight (Carisbrook); June 23 (Thursday), Ryde; June 28 (Tuesday), Leeds; July 6 (Wednesday), Chelmsford, Ealing, Hitchin; July 13 (Wednesday), Maidstone; July 14 (Thursday), Brentwood; July 16 (Saturday), New Brighton; July 28 (Thursday), Bedale. The next list of fixtures will appear early in June. In the meantime, Mr. EDWARD MAWLEY, Rosebank, Berkhamsted, Herts, will be glad to receive the dates of any Rose shows (or other horticultural exhibitions where Roses form a leading feature) for insertion in that list.

GHEENT EXHIBITION.—The system of recording the decisions of the jury followed at this marvellous exhibition deserves to be noted. The jury was divided into thirty-nine sections, and each section elected its own chairman. Moreover, each section was attended by a steward, one of the pupils of the School of Horticulture, who pointed out to the jury where and what were the objects to be adjudicated upon; and by a boy messenger from an orphan school, to whose smartness we have already borne testimony. A note-book with perforated leaves was given to the chairman, on each page of which was printed the number of the competing class, its nature, the awards to be allotted at the discretion of the jury, and the number of competitors, but of course not their names. As soon as the jury had come to a decision in any one class, the chairman registered the result in his note-book, signed it, tore the leaf out, and gave it to the messenger, who hurried off with it to the central office, and returned immediately. In this way mistake was almost impossible, the system worked smoothly, and the judging was accomplished speedily and decisively. We remember in former years at continental shows that the judging was a very lengthy business, partly because the judges occupied their time in gossiping rather than in their proper duties; but on this occasion the judging was done as promptly and efficiently as in England.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held on Monday, May 16, 1898, when a paper will be read by Mr. H. T. EVE (Fellow), entitled "Compensation Values of Cattle Foods—Chemist v. Valuer." The chair will be taken at 8 o'clock.

"HOME GARDENING."—This "manual for the amateur" by W. D. DRURY, and published by L. UPCOTT GILL, 170, Strand, adds yet another to the innumerable small cheap handbooks on gardening

which are already before the public. The author considers that an excuse for issuing his manual is that, in spite of the plentiful literature just referred to, "strange to say, the absolute novice has not been so well catered for." Whether this is the case or not, and whether amateurs will appreciate this special work prepared for them, remains to be proved. It is enough to say that common-sense advice is plainly given as to the ways of cultivating flowers, fruit, and vegetables, and if the novice fail in spite of them, it will not be the fault of his instructor. The book contains a few illustrations, and has a gay-coloured cover.

MISSOURI BOTANICAL GARDEN.—We have received the ninth Annual Report, to March, 1898, of the Missouri Botanical Garden, sent out by the Director, Mr. W. TRELEASE. It is a highly satisfactory account, comprising a record of various additions to the herbarium, library, and garden. The scientific papers included in the volume are:—"Revision of the American Lemnaceae occurring North of Mexico," C. H. THOMPSON; "Notes on *Salix longipes*, Shuttlw., and its relations to *S. nigra*, Marsh, N. M. GLATFELTER, M.D.; "Revision of the genus *Capsicum*, with especial reference to Garden Varieties" (an elaborate monograph, to which we shall refer again), H. C. IRISH; "List of Cryptogams collected in the Bahamas, Jamaica, and Grand Cayman," A. S. HITCHCOCK; "Agave Washingtonensis and other Agaves flowering in the Washington Botanic Garden in 1897," J. N. ROSE; "Species of Cacti commonly cultivated under the Generic name, *Auhalonium*," C. H. THOMPSON; "Miscellaneous Observations on *Yucca*," W. TRELEASE; and other similar articles. The plates illustrating the papers are effective.

HORTICULTURAL CLUB.—The usual monthly dinner was held on Tuesday last, when the chair was occupied by the President, Sir JOHN T. D. LLEWELYN, M.P. Over fifty members and their friends were present, this large number being drawn together to do honour to the valued and respected founder and Hon. Secretary of the Club (Rev. H. D'OMBRAIN), who had that day attained to the ripe age of 80 years, and it had been determined by the members to in some way recognise his long and justly-appreciated services. This intention of the members was admirably carried out by Mr. HARRY J. VEITCH and Mr. GEO. MONRO. During the evening the Chairman, amidst cheers, and in felicitous terms, asked Mr. D'OMBRAIN'S acceptance of a cheque for £63, representing a subscription of £1 ls. each—the maximum amount asked for—from sixty members of the Club, together with a purse, the gift of a lady whose name was not disclosed, as a small token of esteem, and with a sincere and hearty good wish from every member on the celebration of his 80th birthday. Mr. D'OMBRAIN with much emotion feelingly acknowledged the, to him, quite unexpected gift. Words failed him (he said) to express what he felt at the action of his kind friends in thus honouring him, and he could only say that it had given him great pleasure to be of service to the club. He had during his secretaryship formed many dear friendships, which he deeply valued, and in sincerely thanking them for their kindness, asked that they would all accept, what he termed, "an old man's blessing." Mr. MARTIN R. SMITH offered to have the circumstances of the presentation together with the names of the members inscribed on vellum, and presented to Mr. D'OMBRAIN in the name of the club, which offer, needless to say, was warmly accepted. Letters from Dr. MASTERS, and others, regretting their inability to be present, were read by Mr. GEORGE MONRO, who also expressed his personal regret, which was shared in by the whole company, at the absence of their vice-chairman (Mr. HARRY J. VEITCH) through illness. Sir JOHN LLEWELYN being compelled to leave at an early hour on account of his parliamentary duties, vacated the chair in favour of Mr. N. SHERWOOD.

ORCHIDS AT MOORTEBEEK.—M. L. LINDEN writes to us from Brussels to the following effect:—"Certainly the air and the situation play a considerable

part in the cultivation of *Odontoglossum*, and more particularly of *Cattleya*. But this is not all; it is necessary beyond everything else that the plant become properly established. Ill-established, badly cultivated at the beginning they will never thrive. The two first years of cultivation decide the future of the plants, just as early education does that of the man. It has been said that Orchids degenerate in Europe. To my mind the plants have been only badly established. If the air is an important factor, the construction of the house and ability to profit by that air, repotting and watering are other highly important points. At Moortbeek we use rain-water only. The air of Moortbeek is excellent; certainly the best that I know in the environs of Brussels, but I believe that badly-cultivated plants would succeed no better there than elsewhere, for I have proof of it not far from my own doors. I know in the suburbs of London many places which rival Moortbeek, and I am positive that I could succeed in cultivating *Odontoglossum* and *Cattleya* equally well there. I am so fond of England that I am often tempted to make the attempt (*quien sabe?*), unless there are too many successful English growers. [There are many localities we could indicate, but, on the whole, we think M. LINDEN had better stay where he is! ED.]

STOCKTAKING: APRIL.—Actual war and political entanglements continue to play sad havoc with trade, both as to supply and prices. As noted in the Board of Trade returns for April, the imports amount to £40,246,716, as against £35,136,555—for the same period last year—or an increase of £5,110,161, or 14½ per cent. This great increase may be divided between food supplies and materials for the manufacture of textile fabrics, but it may be noted that the heavy supplies of wool and cotton are compared with very low ones for April, 1897. The following is our usual excerpt from the "summary" table of imports for April:—

IMPORTS.	1897.	1898.	Difference.
Total value ...	£ 35,136,555	£ 40,246,716	+ 5,110,161
(A.) Articles of food and drink—duty free ...	11,752,101	14,252,300	+ 2,500,199
(B.) Articles of food and drink—dutiable	2,116,859	1,899,372	— 217,487
Raw materials for textile manufactures ...	5,804,501	7,610,695	+ 2,306,194
Raw materials for sundry industries and manufactures	3,307,117	3,441,017	+ 133,900
(A.) Miscellaneous articles ...	1,038,029	1,174,175	+ 136,146
(B.) Parcel Post ..	73,141	99,117	+ 25,976

The imports for the four months just finished amount in value to £159,317,623, against £152,764,781 for the same period in 1897—an increase of £6,552,842. Our usual piece of "relief" will be found in the figures relating to the imports of fruit, roots, and vegetables for the past month:—

IMPORTS.	1897.	1898.	Difference.
Fruits, raw:—			
Applesbush.	336,314	167,121	— 169,213
Cherries"	331	...	— 331
Plums"	...	1	+ 1
Pears"	1,380	1,355	— 25
Grapes"	2,012	2,259	+ 247
Unenumerated"	56,019	63,760	+ 7,741
Onions"	687,217	613,633	— 23,584
Potatoescwt.	86,167	1,186,653	+ 1,100,486
Vegetables, raw, unenumeratedvalue	£135,240	£131,952	— £3,288

The "plus" in the matter of Potatoes in the above excerpt is the most notable of the series. We come now to the always interesting section devoted to—

EXPORTS,

and here, too, we find the depressing influences of war telling against our foreign trade. The figures for the past month are £17,496,011, against £19,700,122 for April, 1897—a decrease of £2,204,111.

Machinery and millwork show an increase of some £68,255, but in most other sections a decrease is reported—yarns and textile fabrics accounting for £1,280,262 of the decrease. The exports for the four months of the present year amount to £75,203,129, against £78,998,309—a decrease of £3,795,180. In this decrease yarns and textiles figure for £1,804,209; machinery and millwork, £708,256; metals and articles manufactured therefrom, except machinery, £475,153; and a decrease in the value of articles of food and drink, amounting to £269,292, has to be placed to the four months' credit.

Jordan.

CARNE, NEAR PENZANCE.

THE RESIDENCE OF F. ST. JOHN TUPPER, Esq.

[SEE SUPPLEMENTARY ILLUSTRATION.]

CARNE consists of a simply-built house pleasantly overgrown with Ivy, Escallonias, and other evergreen climbers, surrounded by its grounds of fourteen acres, situated on the summit and side of a hill overlooking the town of Penzance. From the house a beautiful view is obtained of Mount's Bay and St. Michael's Mount, and, as the aspect is thus almost due south, the place has great natural advantages for gardening of every description.

The grounds have been laid out with considerable taste. They consist almost entirely of lawns, paths, and shrubberies, the grass being allowed to form graceful bays, and so break the formality of the boundary lines of shrubs. The whole effect is pleasing and moderately reposeful, though the presence of some deciduous forest trees would much improve the appearance of the grounds. The collection of shrubs is fairly extensive, and includes a large number of Hollies and Rhododendrons—many of the latter being in flower on the occasion of my visit in the middle of March.

Very little attempt at flower-gardening has, however, been made. Between the shrubs (which are wisely allowed space for individual development of form) is chiefly bare earth, with the exception of a few clumps of *Romneya*, and an occasional *Pæony* or *Iris*. Spring flowers are almost entirely absent; a few dozen Crocuses planted singly at regular intervals, a few Narcissi, forming a thin line along a shrubbery

border (instead of being judiciously planted in natural clumps), a few *Polyanthuses*, and three *Gentianellas*, appear to exhaust the list of spring flowers at Carne.

There are three well-enclosed plots of ground which might be made little paradises of beauty at the cost of a little judgment and effort. The whole place offers singular facilities for the culture of flowers, and now that the more important and tedious part of the work of making the grounds attractive has been done, in the general laying out of the place and the development of the shrubs for eighteen years, it is to be hoped that the new owner of Carne will take advantage of its situation and make it one of Cornwall's most beautiful flower-gardens. *Harry Roberts.*

LETTUCE FORCING.

LETTUCE growing under glass is by far the most extensive of the vegetable forcing industries in this country (United States). It would be interesting to know why it has developed so far ahead of other greenhouse crops—Tomatoes for instance. It is usually supposed that the class of people who eat what they like regardless of cost is quite large in America; and yet it has been the experience of greenhouse managers, generally, that it is possible, in comparatively few cases, to get such prices for forced Tomatoes, Beans, Cauliflowers, &c., as will make them pay. Of course, one has to take into account the production of early vegetables in Florida, and other southern States, whence Beans and Cauliflower can be shipped with comparatively less expense than can Lettuce; but this does not account altogether for the comparative development of the several forcing industries. But Winter Lettuce is a staple crop now, even in small rural towns, where almost no other "green-groceries" are seen for three or four months in the year. In eastern markets, or more particularly in Boston and its vicinity, the demand is for large solid heads of smooth leaves. Boston Market and Big Boston are two varieties which are grown to supply this demand. Such Lettuce is sold by the head, or by the dozen heads, bringing 1 dol. to 1 dol. & 0 c. (about 4s. to 7s.) a dozen in the city markets, but selling as low as 50 cents (2s.) a dozen in country markets.

In Chicago and other western cities Lettuce is sold by the pound, and varieties of a very different class are grown. The type of western forcing Lettuce is the Grand Rapids, which grows erect, with light green, very curly leaves, and does not make a head. The Grand Rapids type of varieties is easier to handle under glass, and can be sent sooner to market. It is all a matter of custom as to which is better for table use. The plan of selling by weight is evidently fairest to the buyer, and ought to be perfectly satisfactory to the grower, especially for the non-heading varieties of Lettuce. The plan of selling all sorts of vegetables and fruits by weight is more common in the western States. In the large Denver markets almost everything used to be sold in that way, including eggs and Apples. *F. A. W.* [Our illustration (fig. 112) explains itself, and is a reproduction from a photograph of a house used for vegetable forcing, including Lettuces, Tomatoes, &c.]

HOME CORRESPONDENCE.

GARDENING CHARITIES AND GARDENERS' WAGES.—Your correspondent C. C., at p. 268, of the *Gardeners' Chronicle*, bemoans his inability to contribute to the Gardeners' Orphan Fund and other gardening charities on account of the exceeding smallness of his income. Verily his case is a pitiable one, and it is to be hoped there are not many gardeners in the same or similar circumstances. I have an extensive acquaintanceship amongst gardeners, and know that the majority have incomes very much better, though there are, unfortunately, few cases where the gardeners' profession from the salary point of view, can be called "A happy one." I should like to ask the question, whether it can be said of gardeners generally, as was said of the poor widow in holy writ, they have done what they could towards the gardening charities. The sum required

to secure one vote for the election of children to the Gardeners' Orphan Fund is 5s. per annum, or a fraction less than 1½d. per week. Even your correspondent C. C. with his 21s. 3d. per week clear of rent, could afford this, and never miss it. I believe if he even ventured further, and spent 5d. for the Gardeners' Benevolent Fund, and the balance of 1s. to make himself a member of the Oddfellows' or other Benefit Society, he would not regret it or feel himself the poorer, but would ever with a grateful heart realise that it is "More blessed to give than to receive." Granting that C. C. may find a difficulty in giving to charities, can this be said of the 10,000 gardeners whose names are in the *Horticultural Directory*? Verily, no. Looking over the list of subscribers to the Orphan Fund for 1896 (the latest published), I find there are just over 300 practical gardeners who contribute, and while there are a good many who nobly do what they can, and interest

congregate, do they look poverty stricken? They are well clothed, look well fed, seem in high spirits (except perhaps when they don't get the big prizes they had set their minds on), and even show no lack of pocket-money. It cannot be that gardeners are more hard-hearted than other men; and the only explanation seems that, as a class, they have been too much accustomed to rely on their employers and mayhap the nursery and seed trade, relieving them of their duties in the matter of charities. It is time they awoke from their slumbers, and took the load on their own shoulders. Has it never occurred to gardeners that if, say, nine out of every ten of them in employment subscribed 5s. per annum, and they could easily do that, there would be no need of elections to the fund, but ample means would be available for the decent maintenance of every gardeners' widow and child whom death deprived of their bread-winner. "God helps them that help

well grown, present! Mr. Young sowed the seed in September last in large 60-pots, allowing eight plants to a pot. Later, after these had become strong, each clump was shifted into 24-sized pots, and in the repotting, the outer plants were drawn wider. It was but needful to keep the plants near the glass in a greenhouse temperature all the winter, placing small sticks to the stems as they elongated, and eventually getting them well into bloom at the end of March. When I saw the plants, then in full bloom, they were about 2 feet in height. Whilst a pity indeed to cut from them, yet few flowers cut with long stems could be more light or graceful for placing in vases. There are several varieties of *Schizanthus*, all capital for this form of culture. Very beautiful too are the *Clarkias* and *Godetias*, indeed, there are many not less charming. If a novelty be wanting just now in greenhouse decoration, and one tires of seeing so much of stereotype plants, a large collection of autumn-sown annuals grown in pots, should furnish it. Thus would be seen for an original cost of a few shillings, a display of floral beauty that it would with costly plants be difficult to excel. A. D.

A VARIEGATED-LEAVED DENDROBIUM NOBILE.

—We have here a small piece of *Dendrobium nobile* with the foliage prettily variegated, a leaf of which I enclose for you to see. It originated on a plant of *D. nobile* bought about five years ago of the Liverpool Horticultural Co. (as it was then called, now John Cowan & Co.), and this plant was said to be from a new district. Anyhow, when growth commenced that same spring, I noticed a small pseudo-bulb growing quite in the centre of the mass with this variegated foliage; it was a very small growth, only measuring about 4 inches when complete, and each year since the same foliage has been borne by the bulbs, which have increased in size—last season's, the one from which the leaf enclosed came, measuring 14 inches in length. Until this spring the whole mass has been intact, but now the variegated portion has been separated from the rest, and it has a small basket to itself, and the growth it is now making shows the same peculiarity as that previously made. Up to the present date no flowers have been borne, although it is improbable that they would differ from those of an ordinary *D. nobile*, which is only a flower of the usual type. I mentioned this variegated sport to Mr. Cowan this spring, and he writes me that he has never seen a piece like it. *Geo. Ringham, Gardener, Wrotham Park, Barnet.* [The leaf sent by our correspondent is striped creamy-white, the stripes running longitudinally, and the leaf appears to be quite normal in all other respects. ED.]

SPORTIVE CYCLAMEN.—In reply to "A. D."

(p. 286), I may state that a plant with fifty to sixty half-white and half-red flowers, and six or seven flowers or blooms half-red and half-white, and two blooms had only one of its petals red, and the others white, and some of the red ones had white petals. I raised this plant from seed, and I also know there is only one corm in the flower-pot. It is a very striking plant, and no one coming into the house can fail to notice it. *Wm. Smythe, Basing Park Gardens, Alton.*

GRIESELINIA LITTORALIS AND OTHER PLANTS.

—Do you know of *Grieselinia littoralis* flowering in this country? It is doing so with me. Among other interesting plants now in flower or flower-bud, are *Sciadopitys verticillata*, *Xanthoceras sorbifolia*, now expanding its flowers in the greatest possible profusion; *Fabiana*, also promising a profusion of flower, Japanese Maples, *Oreodaphne*, and Himalayan *Rhododendrons*, *R. arboreum*, and *R. Thomsoni*. These have been all standing out-of-doors for several years without any protection, except in the case of the *Rhododendrons*, which had a very slight covering during the severe frost of last year's winter. Indeed, they seem to suffer more from hot dry summers than from cold winters. To the above list I might have added *Rhododendron ciliatum* and a *Rhododendron* sent out by Veitch under the name of *R. racemosum*, both unprotected. *G. J. Allman, Parkstone, Dorset.*

HARDY PLANTS FOR FURNISHING FLOWERS FOR CUTTING.—Although Mr. E. Jenkins is very emphatic in his condemnation of the planting of Daffodil bulbs and those of bulbous Irises during the months of January, February, and March, under the conditions mentioned by me at p. 205, he has not adduced facts which in the least go to weaken the opinion which I expressed there on the subject. I must remind Mr. Jenkins once more, that when I penned my original article on this subject (see p. 205, four lines

FIG. 112.—A BOSTON LETTUCE-FORCING HOUSE. (SEE P. 293.)

themselves in the welfare of the fund, one cannot help being amazed at the small number who subscribe, and ask whether it is carelessness or callousness that is the reason why such a praiseworthy fund is supported by the merest fraction of the profession. Scanning the list more narrowly, I find that only thirteen gardeners in Scotland subscribed for 1896, and still fewer in Ireland. Now there are eight children resident in Scotland receiving the benefits of the Orphan Fund to the extent of £104 per annum. But for the very handsome support given by and through the Scottish Horticultural Association, and by one or two gardeners whom it might be invidious to name, the subscriptions from Scotland seem in inverse ratio to the amount received, and bears out the character of Scotsmen given by a humorous satirist when he describes "Sandy" as "a decent man who keeps the Sabbath and everything else he can lay hands on." There must be some other reason for gardeners not subscribing than poverty. When seen at flower-shows and other places where gardeners

themselves," and if the gardeners of Britain would rouse themselves, shake off their apathy, and quit them like men, the outside assistance of employers of gardeners, the nursery trade (who already give nobly), and others interested in gardening, would be cheerfully added to their own efforts, and very soon in the homes of the widow and fatherless, the aged and the infirm, want would be unknown. *Subscriber.*

SPRING-FLOWERING POT ANNUALS.—Recently invited by Mr. Young, gardener to Mrs. Pearson, on Kingston Hill, to see some remarkably fine and superbly flowered *Gloxinias* of the Chelsea strain which he has, I was not less pleased with the inspection of numerous pots of *Schizanthus pinatus* which I saw in one of the houses, and which were really charming. It was not possible on seeing these annuals to do other than wish that these and many others, not less beautiful, might be similarly grown for greenhouse decoration. What a wealth of beauty would such a collection, if

from top), "I had in my mind bulbs planted in the autumn." And I also beg to assure him, that I still assert that "There is no practical reason why people who may come to the conclusion in January, February, early in March, or, for that matter, as late in spring, if good, dry bulbs of the Daffodil and Iris are then obtainable, that they would like to plant a given space with these popular bulbous plants, should not forthwith do so." "To this," writes Mr. Jenkins at p. 236, "I can only say there is every reason possible;" adding, "for if such bulbs were planted 3 inches deep in February or March, the chances are that 90 per cent. would never raise themselves that year more than the same number of inches above the soil." He then asks, "With such as these, where does Mr. Ward get his new bulb and flower-germ for flowering another year?" By way of answering this question, I will ask Mr. Jenkins if he is aware that thousands of forced bulbs of Daffodils, Hyacinths, Tulips, &c., are transplanted out of the pots into borders and beds every spring—often as late as May—in private gardens, where, as a rule, they flourish and yield abundance of flowers every year; improving in floriferousness and subs'ance the second year from time of planting, after the bulbs have had time to recover from the rough ordeal which they were subjected to in the process of forcing, and to establish themselves in their new quarters? And, if so, how he reconciles this fact with his own dictum? Again, I may mention—by way of convincing Mr. Jenkins of error and unjust remarks he has made in criticizing practical facts—the thousands of Daffodils which are yearly transplanted from Daffodil woods on private places to desirable sites on other parts of the estate in May, and sometimes later in the season, and which bulbs live and flourish to such an extent in their new home as to become a veritable carpet of gold every succeeding spring in the course of a few years. These facts speak for themselves, and at the same time afford a conclusive and indisputable answer to Mr. Jenkins' question in reference to spring-planted Daffodils—"And with such as these, where does Mr. Ward get his new bulb and flower-germ for flowering another year?" Time after time have I made transplantations of the above-mentioned bulbs, and with the results indicated; planting the forced bulbs in holes made 3 or 4 inches deep with the setting-stick, and the Daffodils in holes about the same depth, made with a crowbar, pretty closely together, or rather closely together in clumps, at irregular intervals among the trees in the "home-woods" and grounds, filling up the holes with fine soil where the latter was not loose enough in the planting ground to get washed into the holes with rain. Mr. Jenkins says, "Mr. Ward urges that I must know that thousands of Daffodil bulbs are advertised and sold in January and February;" adding, "True; but who are the buyers? Certainly not practical gardeners or bulb specialists." How does Mr. Jenkins support this assertion, seeing that the said bulbs are largely advertised in trade journals during the months named? I suppose Mr. Jenkins will admit that the trade is composed of practical men and bulb specialists? Your correspondent refers to a bulb sale that he attended in February last, and at which Von Sion Daffodils were put up in cheap lots, some of which, he avers, were not sold, notwithstanding the fact of "at least half-a-dozen Daffodil-growers and specialists" were included in the number of people present. However, I fail to see that this indisposition on the part of six growers and specialists to buy the said bulbs can be accepted as evidence in support of Mr. Jenkins' defence, for the best of all reasons, that in all probability they did not go to the sale to buy bulbs of this kind, and which they evidently did not require. Mr. Jenkins' remarks, "Here was a lost opportunity, for Mr. Ward could have had at least 2600 or 3000 for the taking away." Well, it may interest Mr. Jenkins to know that the middle of February last I planted 4000 double Daffodils in my garden, and a lesser number of Spanish Irises. I have cut several blooms of the former with stems 8 to 9 inches in length, and the foliage of most of them is from 7 to 9 inches high. And I look forward with certainty to these same February-planted bulbs becoming stronger, and consequently more floriferous, each succeeding spring; and, moreover, I feel confident that these bulbs will yield better floriferous results in the spring of 1899 than bulbs of the same size and quality planted next autumn will produce. Sound dry bulbs, when brought in contact with mother earth, of medium texture and fair fertility, during any of the months of January, February, or March, speedily push into root and leaf-growth, and, in a measure, make up for lost time. I need not go into the reason which

induced me to buy and plant the bulbs mentioned above in February, further than to say I consider the bulbs offered were a good bargain, and I was certain that they would grow and flower all right in due time. I do not think Mr. Jenkins would wilfully misrepresent my words, or accuse me of "trying to evade the point at issue," which, however, he does at p. 236 (*re* Francoa "growing and flowering freely when sheltered from north and east winds"), by saying I originally recommended this plant for field-culture, and quite unconditionally. If he will refer to the concluding lines of the third paragraph of my original article, p. 156, he will be convinced of the error he has made in accusing me of "trying to evade the point at issue." In recommending that new plantations of the kinds of hardy perennials mentioned in that paragraph (including the Francoa) be made in light rather than heavy soil of average fertility and depth, I added, "and, if possible, in situations which are sheltered from the north and east winds." I have never "tried to evade the point at issue" in any controversial matter I have been engaged in, but I have sometimes had difficulty in keeping my opponent to the "point at issue." *H. W. Ward, Rayleigh.*

THE FRUIT PROSPECTS.—The blossoms of the Apple, Pear, Cherry, and Plum are very promising. The recent frosts touched a few of the most forward and exposed blooms on some of the Pear-trees, but more than sufficient is left. The trees appear to be doing their duty, and if the climatic conditions of the season are favourable, the pains-taking orchardist will have good fruit crops. Apricots, I fear, will be thin. The blossom was everything that could be desired up to the morning of March 10, when 12° of frost killed the greater part. So grand a fruit as the Apricot ought to be given glass protection. I often wonder how it has, for so long, been left out in the cold, whilst so much care is bestowed on the Peach and Nectarine, which in the opinion of some are inferior fruit to that of the Apricot. *W. Miller, Combe Abbey, April 25.*

—So far, the season is all that could be desired in these parts, and there are prospects of a beautiful fruit harvest. If our friend John Frost will only forego his usual late visit, a record season may be expected. Vegetable crops have benefited by the helpful rains, and with warm sunshine we may hope to closely follow our southern brethren, who will shortly be telling us that they are gathering Strawberries, pulling Peas, and digging Potatoes on warm borders, and other nice things. We do not envy them, unless perhaps when they are penning their notes we have registered our 10° or 12° of frost. Imagine our feelings as we cut our Cabbages and pull our Peas, perhaps a month or six weeks late. Unlike the Pharisee of old, thankful that we are not as other men, we are inclined to ask, "why" are we not as other men? *Arthur Smith, Eden Hall Gardens, Langwathby, May 4.*

PROTECTING PEACH-TREES IN BLOOM.—Seeing that ninety gardeners out of every hundred, at least, recognize and act upon the belief that some protection to the bloom of Peach, Nectarine, Apricot, and similar wall-fruits is needful and beneficial, Mr. Carmichael has shown great boldness in venturing to denounce the practice so strongly as he has recently done. But when it is charged against the practice that it keeps the bees from the blossoms, it should be understood that that objection fails where, as is so commonly the case, the covering remains over the trees in the night only, and is rolled up or removed during the day. But after all it is a case of experience. What are the experiences of the many who do give protection as against the few who give none? Not that it necessarily follows the many may be right, because practice in gardening is often of the rule-of-thumb order, but when the large majority do act in a certain way, there seems to be strong reason to believe that they must have good reasons for taking such course. What harm is done to wall-tree bloom is undoubtedly the result, chiefly, of night frosts, and these are sometimes so severe that Frigi Domo, tiffany, or scrim-canvas offer very little protection. In such case probably the chief service rendered may be to intercept the falling moisture or dew, and thus help to keep the blossoms dryer than otherwise would be the case. But then again there is the fact that moisture at night comes largely from the soil, and if the covering over the Peach-trees, usually at the bottom drawn out some 3-feet from the wall, checks the settling of moisture on the bloom externally, it bottles-in such moisture as emanates from the soil beneath the covering, and prevents its free dispersal

in the air, so that the check to external moisture may not be all gain. It seems late in the day to open a question of this nature now, but it does not follow any the more that our covering or protecting practice has always been right. No doubt there is now ample experience to set the matter at rest if gardeners will only freely give it. *A. D.*

EICHORNIA SPECIOSA, better known under the name of *Pontederia crassipes*, has for many years occupied a prominent position in the tank of the tropical aquatic-house in the Oxford Botanic Gardens. It has always been a shy bloomer here, and on each occasion of its flowering it has invariably been towards the end of the summer. This would lead one to think that exposure to sunlight was a determining factor in the production of its flowers. But this year the order has been reversed, for during the past week it has produced a scape bearing several of its lovely clear rosy-lilac flowers, the upper and largest segment of each being suffused in the middle with rosy-purple, with linear markings of violet, in the centre of which is displayed a conspicuous oval blotch of pale chrome-yellow. It is a very attractive and pleasing plant when in bloom, but unfortunately the flowers are very evanescent. It is figured under the name of *Pontederia azurea* in the *Botanical Magazine*, vol. 56, pl. 2932, but justice is scarcely done to the prettiness of the coloration of the flowers. *W. G. B.*

CYTISUS ANDREANUS x.—I am sending, and should like your opinion concerning some seedling *Cytisus scoparius Andreanus* crossed with *C. præcox*. The *Andreanus* coloured one is of capital habit and a good grower, and is apparently much earlier than *C. Andreanus* (at least, my one plant of *Andreanus* has not a bloom open yet), as to flowering, it is close after *C. præcox* with me. Of the three—all seedlings from the same cross—one is quite upright. None is so early as the *Andreanus* coloured one. The seedlings are growing out of doors, and are two years old. I think the coloured one should be of value on account of its early blooming. *T. Geeson.* [We do not see in the specimens sent any evidence of a cross with *præcox*. The third upright form is a different species altogether.]

CENTRAL AFRICAN COTTON.—According to a paragraph in the *Gardeners' Chronicle*, an entirely new species of Cotton plant has been discovered in Central Africa, which has caused an uncommon amount of interest. Five years ago, Adolf Kyle, an Englishman, saw in the Congo territory, 1,600 kilometres distant from the banks of the river, in a wooded region, a group of Cotton-bushes of a height of 6 metres. Kyle gave some of the seed-vessels to an American farmer. Can the editor say where this farmer now resides, and if I can obtain seeds of the plant, or what would be the price of a cwt. of seed, or tell me where Adolf Kyle is now residing? Also can he inform me, in case I should send to the Congo country, how I could obtain seeds of this plant? *Karl Dignowitz, Bobergasse 2, Sagan.* [We do not think it at all likely that the plant in question is a true Cotton, *Gossypium*. There are many frutescent or arborescent *Malvaceæ* in tropical Africa which produce cottony seeds, but none of any special value. *Ed.*]

Obituary.

A. SIMPSON.—The decease of this well-known citizen of York occurred on the 4th inst. Mr. Simpson was head of the firm of Messrs. A. Simpson & Sons of the Heworth Nurseries, and held a prominent position amongst the nurserymen of the county. He was associated with the Ancient Society of York Florists, by whom and a by wide circle of acquaintances he was very highly respected. His connection with the Society extended from the year 1868, and during a great part of the time he was a member of the committee. He filled the office of steward three years, and in 1894 occupied the position of chairman of the executive, during one of the most successful financial years in the society's history. He had been a prominent member at the York Chrysanthemum show since its beginning, having had charge of the arrangements for the vegetable exhibits—no very light duty, as those know well who are aware that a quantity of vegetables are usually shown. He was of robust physique, and was seldom ill. His death was scarcely antici-

pated, and his illness but of short duration, a paralytic seizure being the immediate cause of death. The interment took place on the 7th inst., at York Cemetery, and was preceded by a service at St. Thomas's church. Many of the deceased's colleagues were present, and the chaplain of the Ancient Society of York Florists (Rev. H. Vyvyan) assisted in the service. Deceased was in his sixty-eighth year, and leaves three sons and two daughters. *J. L.*

MR. JOHN WEIR.—We have received a private intimation of the death, on the 28th ult., of this old servant of the Royal Horticultural Society. Few persons, we believe, were aware of his existence, for his name appeared long ago in Britten & Boulger's *Biographical Index* of deceased botanists, though, of course, no date could be assigned to the event. His life has been a sad one indeed, and, happily, almost without parallel. John Weir went to Brazil in 1861, as collector for the Royal Horticultural Society, and after spending about two years there, he proceeded to New Grenada, where his active career soon terminated. He had an attack of fever, "which, after a few days, went off, leaving him paralysed in all his limbs, from the neck downwards." This was in the autumn of 1864. But what a deplorable condition for a young man in a distant country! However, he met with good friends and kind nursing, and Mr. F. Stacey, H.B.M.'s Consul at Santa Martha at the time, at once communicated with the Royal Horticultural Society. On receiving this news, the Council of the Society directed that every care and attention should be paid to Mr. Weir, and that he should be sent home as soon as he was able to bear the voyage. He came home in the autumn of 1865, and it was soon recognised that his case was a hopeless one.

An appeal was made to the Fellows of the Society for subscriptions towards a fund to provide for the helpless man and his wife. This appeal was strongly supported in the *Gardeners' Chronicle* for 1865 (p. 1179), and again in 1866 (p. 170). What the exact result was we do not know, but poor Weir lingered on under the care of a devoted wife until the end of last month. As stated in the columns of this journal in the first place cited, during his brief career as a collector, Mr. Weir introduced many beautiful plants. Among other things he introduced a large number of living Orchids, but the cultivation of Orchids was not so well understood then as now, consequently fewer stand to his credit than might otherwise have been the case. Lists of the plants he sent home, together with descriptions of new species, will be found in the *Proceedings* of the Society between 1863 and 1865. Apart from this, we have abundant evidence of Weir's industry and keenness of observation. In addition to flowering plants and Ferns, he made a very extensive collection of mosses and Liverworts, including numerous new species, which were published in vol. xii. of the *Journal of the Linnean Society*. He retained a considerable portion of his collections till within a few days of his end, when, at his special request, it was sent to Kew. *W. B. H.*

Mr. A. G. Munro of New Barnet, furnishes the following interesting particulars of the deceased:—

"Sir Clement Markham speaks frequently and highly of him in his important publication. The two pleasures of poor Mr. Weir's life for years past have been his books and his garden; and though paralysed in a degree such as would have taken the very heart out of many men, he used to bind in leather the various horticultural papers and reviews which he took in. Indeed, the handsome rows of volumes now on his book-shelf would delight the editors who were responsible for the single weekly or monthly issues. Whenever a neighbour desired a little insight into botany, nothing gave Mr. Weir greater pleasure than to give of his rich botanical learning freely, concisely, and to the benefit of those consulting him.

"His house, Clydesdale Cottage, commands a fine view of the East Barnet Valley, and, in summer-time, Mr. Weir would either be sitting under an awning on a garden-seat in the middle of his plants and flowers—many of the latter being the homely and familiar

ones of the best species—or leaning over the wicket-gate, ready for a chat with a passing neighbour. The beauty of his garden was an admiration throughout the immediate neighbourhood. During the whole of his long sufferings he was patient and genial. The greatest blessing in his sad lot was that he had a devoted wife, who scarcely left his side night or day. I need hardly add that his interest in Kew remained keen to the end."

DR. ALEXANDER PATERSON.—Horticulturists near and far will regret to hear of the loss of the genial doctor, who never seemed so happy as when engaged in horticultural pursuits, dispensing hospitality, or sharing his pleasures with horticulturists. For many years one of the most highly valued pleasures of the great horticultural shows at Edinburgh was the day for the judges, the visitors, the pressmen, and jurors, to visit Dr. Paterson's gardens at the Bridge of Allan. These meetings and reunions became red-letter days to many distinguished horticulturists, and their memory lingers in their hearts and heads.

For years it was one of the doctor's special pleasures to send the Queen his choicest Orchids on her birthday, or present her at the Perth station with his richest treasures on her journey to and from her highland home at Balmoral. There are few more pathetic incidents than Dr. Paterson, with the stately grace of a venerable knight of the olden time, bending lowly to enrich his Sovereign with his sweetest and freshest flowers.

For some years Dr. Paterson has suffered from failing health. This compelled him to reduce his treasures, and part with the bulk of his favourite plants. While regretting this serious curtailment of his pleasures and also the loss of his wider experience to horticulture, we must bear in mind that, but for his delicate constitution, the probability is he would never have been an Orchid-grower, an antiquary, or the founder of the great health resort of the Bridge of Allan. His delicate health drove him out of Edinburgh, where he had begun to practise; and having obtained fresh vigour and renewed strength from the Bridge of Allan and its environs, he asked others, similarly afflicted, to do likewise, and with the happiest results.

Up to the last almost Dr. Paterson lived three or more lives—that of the healing, helpful physician; the other two are perhaps more pithily expressed by the statement that he lived in a garden and in a museum. While in horticulture he had also had special hobbies, and had ridden some of them, such as Orchids and Pitcher-plants, as hard as most men; yet his tastes seemed broad and catholic, embracing hardy trees, shrubs, herbaceous plants, alpinists, Cacti, succulents, bulbs, foliage and flowering plants. Neither had his interest in horticultural literature declined in the least. He was an occasional correspondent of the *Gardeners' Chronicle* for many years.

For very many years Dr. Paterson had done good work for horticulture and among horticulturists, and he remained faithful and true to his calling till the last. Living and almost dying in his garden, fondling, growing, training, learning, loving his plants and flowers. 'Tis ever thus with the true gardener, whether amateur or professional. The true love of Nature and of plants is without beginning of days or end of life. It meets us on the threshold of life, and hardly leaves us at the close. *D. T. F.*

SOCIETIES.

ROYAL HORTICULTURAL.

MAY 10.—Just as on former occasions, immediately precedent to the Temple Show, the meeting on Tuesday last in the Drill Hall, James Street, Westminster, was marked by a much smaller display of plants and flowers than has occurred for some time. The general endeavour to make as good a show as possible at the greatest exhibition of the year, causes many of the exhibitors to husband their resources during the few preceding weeks, and anyone who has a really good novelty for presentation at about this period, prefers to wait for the additional honour of an award being granted at the Temple.

We saw the last of the Narcissi at the previous meeting, there being very few staged on Tuesday, but there was a most extensive collection of Tulips from Messrs. BARR & SONS, and other hardy flowers from Messrs. PAUL & SON.

Groups of pot Roses from Messrs. W. PAUL & SON were very attractive and showy, and lovely cut Roses from Mr. G. MOUNT, of Canterbury, were again evident. Awards of Merit were recommended by the Floral Committee to two varieties of Indian Azaleas; to three Alpine Auriculas; to a strain of scented Auriculas, and to a double-flowering variety of *Alyssum saxatile*. Before the Fruit Committee were presented the first Nectarines and Peaches of the season, and some excellent fruits of Royal Sovereign Strawberry; five Awards of Merit being recommended to Radishes shown from the Royal Horticultural Society's Gardens.

Orchids included several first-class novelties, and are referred to in another column. In the afternoon, Professor Geo. Henslow gave an interesting discourse upon some of the plants before the meeting.

Floral Committee.

Present: W. Marshall, Esq., Chairman, and Messrs. C. T. Druery, Owen Thomas, Jno. Fraser, R. Dean, Geo. Stevens, W. Howe, Jas. Hudson, John Jennings, Thos. Peed, H. B. May, J. Fraser, Geo. Gordon, J. D. Pawle, Chas. E. Pearson, Chas. Jeffries, Chas. E. Shea, H. J. Cutbush, E. T. Cook, D. B. Crane, T. W. Sanders, H. Turner, C. Blick, Cecil E. Cant, E. Mawley, and Jas. Walker.

Mr. JAS. TURNER, Royal Nurseries, Slough, made an exhibit of new varieties of *Azalea indica*. Awards of Merit were recommended to two of these, *Mme. Joseph Vervaeke* and *Ami Chas. Vermeire*. The former is a large double pink-coloured flower, with deeper blotch; the latter, crimson colour single flowered, very free. Dryad, double white; Louise Cuvelier, also double white; M. Chas. Vuylsteke, an all double crimsoned-flowered, and President A. d'Haene, President Van Imschoot, semi-double dark crimson, La Printemps, a fine showy crimson, are all good varieties.

Mr. TURNER also showed a dozen-and-a-half plants of the Princess May variety of *Souvenir de la Malmaison* Carnation. This richly-coloured variety was in capital condition, the plants being well-grown, the flowers were large and finely-coloured.

A sweet-scented strain of yellow Auriculas was shown by Mr. DAVID STORRIE, St. Madoes Cottage, Glencarse, Perthshire, N.B. Both plants and flowers were very fine and large, there being several shades of yellow in the varieties. It was said the plants have always been grown, wintered, flowered, and seeded in the open border, and have had no protection of any kind at any time. The variations in colour have arisen through accidental fertilisation, no hand pollination ever having been attempted. The strain has been obtained during the past fifteen years by selection from the produce of one original yellow-scented plant that occurred in the ordinary border seedlings. Some of the varieties were more attractive than others, as *Souvenir de Helène Thérèse* and *Souvenir de Sir James* (An Award of Merit was recommended the strain).

Mr. JAS. DOUGLAS, Edenside Nurseries, Great Bookham, exhibited a collection of alpine Auriculas, and Awards of Merit were recommended to three varieties—*Perfection*, deep crimson, with yellow eye; *Dean Hole*, much the same colour, but in two shades, and the yellow in this case of a paler tint; and *Nixa*, a very perfect flower, with yellow eye, and deep crimson pipe, edged light red.

Messrs. PAUL & SON, Old Nurseries, Clonsant, obtained an Award of Merit for a double-flowered *Alyssum saxatile*, and they also showed four fine new Cannas, named *Iona*, *Uncas*, *Orion*, and *Sirdar*. The three first-named varieties were self-coloured, and *Sirdar* had scarlet flowers with an irregular narrow border of yellow. Messrs. Paul & Son also contributed a group of hardy plants in flower, including the pretty blue-flowered *Phlox canadensis*, light blue flowers, and P. G. F. Wilson, lilac coloured, and other species; *Primula Sieboldi* Brilliant, a bright-coloured variety of this popular species; *Alyssum saxatile* variegatum, *Iberis superba*, sprays of double flowered Cherries, *Pyrus malus* Schiedackeri, with rose and white flowers, and a pan of the tiny white flowered *Arenaria balearica* (Silver Banksian Medal).

The collection of Tulips and hardy flowering plants from Messrs. BARR & SONS, King Street, Covent Garden, London, extended along the whole length of one of the long central tables, and was awarded a Silver-gilt Flora Medal, the highest award made by the committee on this occasion. The collection was rich in species, and included the brightly-coloured *Tulipa elegans*, and its white-flowered variety; *T. strangulata*, yellow, and the variety named *Picta*, with purple or black base, and segment marked with red; *T. retroflexa* (yellow), and others, including a few of the Parrot varieties. Darwin Tulips were represented by numerous flowers, mostly dull in colour, and some of the prettiest varieties shown were *May Queen*, *Glow* (crimson), *The Sultan* (an extremely dark-coloured flower), *Dorothy* (silvery heliotrope), *Aurora*, *Queen of Roses*, and *Phyllis*. The hardy flowering plants staged included a number of hardy Orchids, such as *O. papilionacea*, *O. mascula*, *O. italica*, and *O. bombylifera* (Silver-gilt Flora Medal).

From B. BENNETT, Esq., Chervell Park, Dunstable, was shown an inflorescence of *Dracena indivisa*; and Mr. J. T. GILBERT DYKE, Bourne, Lincoln, had a bunch of double-flowered Anemones.

Mr. J. JAMES, Woodside Nurseries, Farnham Royal, Slough, exhibited some *Cinerarias* raised from crosses between the garden *Cineraria* and *S. cruenta*, afterwards recrossed with *S. lanata*. These were much dwarfier in habit than the hybrid *Cinerarias* shown previously by Messrs. Sutton and Veitch.

the foliage taking somewhat after that of *S. lanata*. These may be the precursors of a fine strain, but at present are of botanical interest only.

A group of plants from Messrs. W. BALCHIN & SONS, Hassocks Nurseries, Sussex, included batches of *Boronia serrulata*, *B. heterophylla*, *Erica perspicua*, and the purple-flowered *Browallia elatior*, all of them bearing evidence of skilful cultivation.

Mr. H. B. MAY, Dyson's Lane Nursery, Upper Edmonton, showed a group of pretty *Codiaeums* (*Crotons*), staged thinly, and interspersed with a few Ferns, and other plants. Of broad-leaved ones, the best conditioned were Goldi, Thomsoni, Reidi (a very fine piece), and Baron Selliere. The prettiest of the fine-leaved section was a well-grown plant of the rather difficult Aigburth Gem, and Golden Ring, with rich-yellow, waved and twisted leaves was good, also Youngi, Gordoni, Superba, Flamingo, &c. Altogether there were forty varieties staged in this representative collection of well-grown plants (Silver Banksian Medal).

Mr. GEO. MOUNT, again made a display of lovely Rose-blossoms, and was awarded a Silver Flora Medal.

Messrs. W. PAUL & SONS, Waltham Cross Nurseries, Herts, had a group of pot Roses on either side of the entrance to the hall. Most of the plants being freely flowered they composed a showy picture, and boxes of cut blooms placed in front of them greatly increased the effect. Some of the older standard sorts were represented by specimens of considerable size, and the newer ones, such as Queen Mab and Enchantress, by younger specimens. The varieties that created the best effect were Victor Verdier, La Rosière, Alphonse Souperet, Jeannie Dickson, Mme. Falcot, Gustave Piganneau, Mlle. Fanny de Forest (pure white), Duke of York, Queen Mab, and Enchantress (a Silver Flora Medal was recommended to this exhibit).

A group of East Lothian Stocks in flower, and boxes of *Pyrethrum aureum* (Golden Feather), was staged by Messrs. F. MILLER & CO., 267, Fulham Road, London.

Messrs. J. CHEAL & SONS, Crawley, showed a few sprays of flowering shrubs, also Violas in sprays.

A pretty group of plants from Messrs. W. CUTBUSH & SON, Highgate, London, N., included some finely-flowered plants of *Hydrangea hortensis* var. Thos. Hogg, *Souvenir de la Malmaison* Carnation var. Princess May, several Indian and mollis Azaleas, *Erica ventricosa coccinea* 'minor', *E. v. magnifica*, *E. perspicua nana*, *Boronia heterophylla*. A few graceful specimens of Japanese Maples, *Wistaria sinensis*, and Ferns, made the group a very attractive one (Silver Banksian Medal).

Mr. GEO. STEVENS, St. John's Nursery, Putney, showed a few new Carnation flowers, but no awards were obtained by these, the committee being desirous of seeing the habit of the plants.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, Chelsea, showed a group of plants, including *Anemone nemorosa flore-pleno*, a dwarf double-white flowered variety; a fine lot of *Daphne Cneorum* major, also plants of *Hydrangea japonica* *Mariesii*, and *H. j. flore-rosea*, the former variety being a very showy plant exhibited at the Temple Show last year; sprays of *Rubus deliciosus*, *Sambucus racemosa serratifolia* *foliis aureis*, also *Citrus trifoliata*, and plants of the white-flowered *Cytisus Schipkensis*; a pretty light purple-coloured *Aubrietia* known as *Souvenir de W. Ingrami*; and *Nothospartium australe*, an extremely minute-flowered *Leguminosae*, a hardy plant, with aggregated flowers along three parts the length of each stem.

Orchid Committee.

Present: Henry Little, Esq., in the chair; and Messrs. T. B. Haywood, De B. Crawshaw, J. Douglas, W. Cobb, T. W. Bond, E. Hill, J. Jaques, H. Ballantine, H. M. Pollett, T. Statter, J. Gabriel, H. J. Chapman, F. J. Thorne, W. H. Young, W. H. Protheroe, and Jas. O'Brien (Hon. Sec.).

Messrs. J. VEITCH & SONS (Ltd.), Royal Exotic Nursery, King's Road, Chelsea, staged an extensive group, and were awarded a Silver-gilt Flora Medal. Of new plants, the gem of the group was the pretty *Spathoglottis* × *aureo-Veillardii*, with charming *Phalenopsis*-like flowers of a clear chrome-yellow, the sepals having a few crimson markings, and the petals being profusely dotted with crimson. The side-lobes and tip of the front lobe of the lip, the column, and also the reverse of the flower, were tinged with crimson (First-class Certificate); another fine novelty was *Laelio-Cattleya* × *Wellsiana albida* (*C. Trianae* × *L. purpurata*), with white sepals and petals, and rich purple lip. Other remarkable plants were a fine example of *Cattleya intermedia* *alba*, some *Laelia* × *Latona*, and *Cattleya Schroderae*, of which *C. S. coerulescens* was the most striking; the typical rosy-petalled *Laelio-Cattleya* × *Wellsiana*, and several remarkably fine plants of *Cattleya Mendeli*, including one of a wholly bluish-white tint; besides excellent *Odontoglossums* of species, the handsome *Brassia brachiata*, good examples of *Masdevallia Veitchiana*, *Epidendrum Wallisii*, *E. elegantulum*, *Calanthe masuca*, *Cirrhopetalum picturatum*, *Cypripedium Mastersianum*, *Angraecum modestum*, &c.

Messrs. HUGH LOW & CO., Clapton, exhibited a group in which the following were prominent, viz., *Vanda teres candida*, *Bulbophyllum Claptonense* with yellow flowers striped with dark crimson, a number of varieties of *Odontoglossum crispum*, *Cattleya Mendeli*, *Laelia purpurata*, and others; also *Cypripedium Rothschildianum*, &c. (Silver Banksian Medal). WELBORE S. ELLIS, Esq., Hazelbourne Dorking (gr., Mr. W. S. Barrell), exhibited a number of plants of *Odontoglossum crispum* of an excellent type and

capitally grown; likewise a couple of fine plants of *Miltonia vexillaria* that were profusely flowered.

FRED HARDY, Esq., Tyntesfield, Ashton-on-Mersey (gr., Mr. T. Stafford), showed *Sophro-Cattleya* × "George Hardy" (*C. Acklandiae* × *S. grandiflora*), a pretty dwarf hybrid, in growth like a slender *Cattleya* *Acklandiae*, and bearing a neatly-formed flower of a reddish tint, with a yellow patch at the base of the lip. It is a novel cross, that is showy and distinct in character (Award of Merit). Mr. HARDY's group comprised *Cattleya* × *Lowie-Mossiae*, *Cypripedium* × *Goweri magnificum*, and some flowers of *Sobralia macrantha* *alba*.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr., Mr. J. Davis), showed *Cattleya intermedia* *Fowler's* variety, a handsome variety that resembles some of the forms of *Laelio-Cattleya* × *Schilleriana*, with which it may be a secondary cross, though the pollinia were those of a typical *Cattleya*. The inflorescence consisted of five flowers of a bluish-white tint, the front lobe of the lip, which is crumpled and expanded, and of a ruby-red colour. It is quite distinct from any other form of its class (Award of Merit).

WALTER COBB, Esq., Dulcote, Tunbridge Wells (gr., Mr. J. Howes), again showed *Laelio-Cattleya* × *Hippolyta*, Dulcote variety, which had previously received an Award of Merit, and which on this occasion received a First-class Certificate. It is the finest variety yet shown at the Royal Horticultural Society's meetings. The inflorescence was short and robust, and bore five flowers of a large size, and of a salmon-tinted orange colour.

Major JOUCEY, Sunningdale Park, Sunningdale (gr., Mr. F. J. Thorne), showed a fine plant of *Anguloa Ruckeri*, with six flowers proceeding from one growth (Cultural Commendation); and the rare *Eriopsis rutidobulbon*, with an arching raceme of handsome flowers, the sepals and petals of which are yellow, edged with purple, the expanded side-lobes of the lip bearing a delicate tracery of purple, and the white front lobe some purple spots.

FIG. 113.—A MARKET-BUNCH OF RADISHES.

THOS. STATTER, Esq., Stand Hall, Whitefield, Manchester (gr., Mr. R. Johnson), showed *Cypripedium* × *macrochilum giganteum* *superbum*, with very large flowers of a lighter tint than those previously observed.

C. L. N. INGRAM, Esq., Elstead House, Godalming (gr., Mr. T. W. Bond), showed *Laelio-Cattleya* × *Fascinator* (*C. Schroderae* × *L. purpurata*), a very fine hybrid, with sepals and petals of a pale rose colour, the broad front of the lip being rich purplish-crimson; the throat white, with a yellow tinge in the centre. It very closely resembles *L.-C.* × *Aphrodite* (*C. Mendeli* × *L. purpurata*), of which the forms "Eudora" and "Regalis" have previously been shown from the same gardens (First-class Certificate).

Messrs. LINDEN, l'Horticulture Internationale, Parc Leopold, Brussels, staged an effective group of cut spikes of fine varieties of *Odontoglossum crispum* and *Miltonia vexillaria*, one grand branched spike of which bore sixty-five flowers. There was a distinct sheen observed on the *Odontoglossums* seldom seen here.

W. G. SOPER, Esq., Harestone, Caterham Valley (gr., Mr. A. Wood), showed a plant of *Miltonia vexillaria* with fine flowers, and in regard to which it was said that the drainage in the pot (as in others grown with it) consisted of lumps of chalk, which were supposed to have a beneficial effect.

REGINALD YOUNG, Esq., Fringilla, Linnet Lane, Sefton Park, Liverpool (gr., Mr. T. Poyntz), showed *Cypripedium* × *Belus* (*Harrisianum nigrum* ♀, *Mastersianum* ♂), a very singular-looking hybrid, that approaches *C. Mastersianum* in form and substance. The upper sepal was green, furnished with a few purple markings inside the pale rose margin; petals and lip are of a brownish-yellow colour, with purple markings. The cross was effected in March, 1891; the seed was sown January, 1892; seedlings appeared in August, 1892; and the first flower in April, 1898.

Mr. J. ROBSON, Bowdon, Cheshire, showed a form of *Odontoglossum* × *Rochfordianum* (? *Hunnewellianum* × *crispum*), a class with rather small flowers, which has appeared in various collections lately. Flowers yellowish-white, spotted brown.

F. W. MOORE, Esq., Royal Botanic Gardens, Glasnevin, Dublin, showed *Epidendrum chitagenae*, a curious species

with yellow flowers, the sepals and petals of which were spotted on the inner halves with purple, the front lobe of the lip being also dark purple (Botanical Certificate). *Epidendrum Brassavole*, and *E. campylostylix*. PHILIP CROWLEY, Esq., Waddon House, Croydon (gr., Mr. J. Harris), showed a good form of *Cypripedium hirsutissimum*.

Fruit Committee.

Present: Philip Crowley, Esq., chairman, and Messrs. Geo. Bunyard, Jos. Cheal, Jas. H. Veitch, G. W. Cummins, W. Gleeson, A. H. Pearson, T. J. Saltmarsh, Alex. Dean, J. W. Bates, W. Farr, Geo. Woodward, Geo. Wythes, G. T. Miles, F. Q. Lane, H. Balderson, J. Smith, G. Reynolds, G. Norman, Robt. Eife, and W. Poupart.

The best Apple in the competitive class for flavour was Herefordshire Pearmain, shown from a standard tree by C. P. SEROCOLD, Esq., Taplow Hill, Maidenhead (gr., Mr. R. Bullock); 2nd, Calville Rouge from cordon on Paradise stock against wall, and exhibited by Mr. GEO. WOODWARD, Barham Court Gardens, Maidstone. There were three other dishes.

A 2nd prize was awarded to Pear Beurré Bretonneau, shown by Mr. C. HERRIN, Dropmore Gardens, Maidenhead, who described the variety as ripening very late, being fairly good after a hot summer, and useful on account of its good keeping qualities.

Strawberry Laxton's Royal Sovereign was shown in magnificent form by Mr. Geo. Norman, gr. to Lord SALISBURY, Hatfield House, Hatfield, Herts. He had about ten dozen fruits of enormous size, and was deservedly awarded a Silver Knightian Medal. Two dishes of smaller fruits were shown by A. HENDERSON, Esq., Buscot Park Gardens, Faringdon, Berks. Mr. Henderson also exhibited a white-fleshed juicy Melon from a cross between Countess × Hero of Lockinge.

Rivers' new Nectarine, Cardinal, was capitally shown by Mr. Jas. Hudson, gr. to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, who had sixteen fruits. They were taken from pot-trees started on December 2, and the first fruits were gathered on May 2 (Cultural Commendation).

A second Cultural Commendation was awarded to a dish of Peaches, Alexander, very fine in size and colour, from Mr. John Ryder, gr. to Dowager Countess of LIMERICK, Hawke-wick, St. Albans. A dish of Waterloo Peaches of moderate quality was shown by C. BOYER, Esq., Tewkesbury Lodge, Forest Hill (gr., Mr. W. Taylor).

A collection of six dishes of French Beans from Mr. GEO. WYTHES, Syon House Gardens, Brentford, and awarded a Vote of Thanks, included the varieties Early Forcing, Mohawk, Sutton's "No. 66," Ne Plus Ultra, Syon House, and Wythes' Improved Mohawk. Mr. WYTHES also showed a seedling variety of Cabbage-Lettuce.

Upwards of a score varieties of Radishes were shown in bunches from the Society's garden at Chiswick, where they had been cultivated beside each other. Five Awards of Merit were granted to these, the selected varieties being Sutton's Forcing White Olive, Sutton's Carmine Olive, Barr's First-of-All White Olive, Barr's First-of-All Scarlet, and Wood's Frame Red, the last-named sent to Chiswick by Messrs. Watkins & Simpson, and being the only long Radish given an award. The two white ones Certificated appeared for practical purposes to be similar to each other.

ROYAL BOTANIC.

MAY 7.—At a meeting held on the above date, Dr. R. Boxall in the chair, Col. Sir Howard Vincent, M.P., Col. C. H. Thompson, Mrs. E. Boyton, Miss Hillier, Miss F. B. Owen, Miss Drummond, and Mr. G. P. Barker, were elected Fellows; and Mr. K. J. Marks, a member of the Society.

The donations to the Society's collections included two large Orchids, *Caelogyne* from Lady Grimthorpe; and from Mr. John Price specimens of four varieties of Sugar Canes from the West Indies.

Dr. COODE ADAMS gave the second part of his paper on "Cacti," dealing more particularly with the *Opuntias*. One species of which is the Prickly Pear of the south, whose acclimatisation in South Africa has been an unfortunate thing for the colonists, since it is over-running whole districts, and no one seems able to eradicate it. A large number of species of the family, many remarkable for the beauty and gorgeous colouring of the flowers, was shown at the meeting by Messrs. A. W. Young & Co., Stevenage, to whom a vote of thanks were passed.

MAY 11.—The annual summer show under the auspices of the above Society was held on Wednesday last in the Gardens of the Society, in Regent's Park. In the *Gardeners' Chronicle* Almanac this event is set down for June 8, according to information supplied to us in December last by the Secretary to the Society. The exhibits were arranged, as usual, under a large tent over the ground specially laid out for this and similar purposes. There was no sign that competitive exhibitions will again become popular in these gardens, where years ago so many keen, if bloodless battles have been fought.

There were several creditable exhibits staged in the competitive classes, but in most cases they were alone, or competed with inferior collections. Fortunately a fine display was made by the trade exhibits, to which, in a very large measure, the success of the exhibition was due. The rough winds prevalent at times caused some anxiety for the safety

of the tent, probably more easily aroused owing to the *flascos* due to wind at Shrewsbury and York last season.

In conjunction with this show, the National Tulip Society held its annual exhibition of florist's Tulips, but the result is to further demonstrate the lack of interest there is at the present time for the florist's Tulip. The date was too early also, and many of the flowers staged had been cut and placed in heat to induce them to expand.

HONORARY EXHIBITS.

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, decorated a mound with dwarf, freely-flowered plants of Turner's Crimson Rambler Rose, interspersed with *Spiraea astilboides*, *Hydrangea hortensis* and the white variety Thomas Hogg, and various ornamental-foliaged plants.

A nice group of varieties of Indian Azaleas was put up by Mr. CHAS. TURNER, Royal Nurseries, Slough, including those shown before the Royal Horticultural Society on the previous day, with considerable additions. Most of the plants represented new varieties, and were deep and pure in point of colouring, the proportion of double ones being considerable.

Messrs. JNO. PEED & SONS, Roupell Park Nurseries, Norwood Road, London, S.E., exhibited groups of *Cordylines* (*Dracenas*) and *Caladiums*. Some of the most attractive of the former were Tennyson, Madame Bergman, Prince Manouk Bey, Frederica, Berkleyi, and Lord Wolseley.

Mr. Kelf, gr. to Mrs. ABBOT, South Villa, Regent's Park, had a group of miscellaneous flowering and foliage plants.

Messrs. W. CUTBUSH & SON, Highgate Nurseries, London, N., had a group of miscellaneous flowering and foliage-plants, including some large flowered *Souvenir de la Malmaison* Carnations, the group as arranged presenting a very attractive feature.

Messrs. WM. PAUL & SON, Waltham Cross Nurseries, Herts, displayed a capital group of pot-Roses, similar to the one staged on the day previous at the Drill Hall. In the Botanic Gardens, however, the site being so much more favourable to effective arrangement, the group presented a better picture.

Mr. GEO. MOUNT, Canterbury, had five large boxes for the display of Rose-blossoms, and a few with larger stems were shown in bottles.

Messrs. JNO. WATERER & SONS, LTD., Bagshot, Surrey, showed a group of Japanese Maples, in small specimens representative of a great number of varieties.

Mr. THOS. S. WARE, Hale Farm Nurseries, Tottenham, had a fine group of hardy flowering plants, in the centre of which were grouped together a number of *Orchis* species, and *Darlingtonia californica*. The group itself owing much of its brightness to several plants of *Tulipa Greigi*.

A capital group of miscellaneous plants was staged by Messrs. JOHN LAING & SONS, Forest Hill Nurseries, London, S.E., in which the many species of stove foliage plants were brightened by *Gloxinias*, double and single-flowered *Begonias*, bright coloured *Caladiums*, *Streptocarpuses*, *Anthuriums*, &c. The general quality of the plants shown was very good. A new *Caladium*, named *Guaralinguetor*, with large richly-coloured leaf, bordered green, has the appearance of being a very good one. Several plants were shown of a new *Cordylina*, named *Rose Laing*, with leaves about 1½ inch wide, slightly recurved at the tips. Most of the young leaves were salmon-red coloured, and if the plants will readily colour to this extent the variety will be most effective. A fine new scarlet double-flowered tuberous-rooting *Begonia* was labelled *Earl of Dartmouth*. Messrs. Laing also exhibited a stand of florists' specialties.

Messrs. B. S. WILLIAMS & SON, Upper Holloway, London, N., had a very large group of *Orchids*, inclusive of *Cattleyas* *Lawrenciana* and *Mendeli*, *Calanthe Sanderiana* and *veratrifolia*, *Ada aurantiaca*, *Cymbidium Lowianum*, *Cypripedium Sedeni candidulum*, and seven other *Cypripedes*, *Lælia purpurata*, *Masdevallia ignea*, *Dendrochilum latifolium*, *Odontoglossums crispum*, *Pescatorei*, *cirrhosum*, *luteo-purpureum*, &c. *Oncidium concolor*, *Trichopilia lepidia* and *Vandas tricolor*, *suavis* and *teres alba*, &c. Many plants of *Anthurium Scherzerianum* too were staged, and a few good *Cliveas*, *Mollis* *Azaleas*, *Lilacs* and *Fricas*, and a pretty bright scarlet *Canna*, with very narrow margin of yellow, named *Mrs. Fairman Rogers*.

Messrs. WILLIAMS also showed from their establishment, 169, Piccadilly, a collection of florist's specialties, the best features in which was a basket of exquisite *Roses*, and one of *Odontoglossums* and *Souvenir de la Malmaison* Carnations. A scarlet shower bouquet of *Anthuriums* and *Raspail* *Pelargoniums*, with flowing ribbons, was effective, and there was a mirror, the frame of which consisted of flowers of a white East Lothian stock.

Messrs. BARR & SONS, King Street, Covent Garden, made even a greater show of Tulips than at the Drill Hall on the previous day, and tastefully arranged on the grass the exhibit was one of the gayest in the tent. Though especially rich in species of *Tulipa* and varieties of the Darwin section of Tulips, the collection included a good number of florist's flowers as well as others of the Parrot type.

Messrs. T. RIVERS & SON, Sawbridgeworth, exhibited sixteen finely fruited standard trees of their new *Nectarine*, *Cardinal*. This excellent variety for forcing was sent out with a reputation for ripening ten days earlier than *Early Rivers*, and many gardeners have already proved that such a description understates the time gained.

A collection of first-class vegetables was shown by Mrs. W. GIBB, Amptill House, Amptill (gr.), Mr. W. J. EMPSON, Potatoes, Asparagus, Mushrooms, Spring Cabbages, Broccoli, Carrots, Kale, Onions, Cucumbers, Tomatoes, French Beans, and enormous Leeks were very fine. The exhibit also included Bananas, Royal Sovereign Strawberries, Apples, and Pears, and Beans and Peas fruiting in pots.

COMPETITIVE CLASSES.

The exhibits described below were the most noteworthy. Messrs. J. PEED & SONS staged a very nice group of *Caladiums*, some of the better known sorts being represented by good-sized specimens, the newer ones, such as *Lady Mawley*, *Silver Cloud*, *Ville de Hambourg*, &c., by smaller ones; but all the plants were very pretty.

The 1st prize for ten *Roses* in pots was taken by Messrs. G. JACKMAN & SON, Woking, who had very large specimens of *Magna Charta*, *Sénateur Vaisse*, *Comtesse de Serenyi*, *Madame Lacharme*, *Duchess de Morny*, *Crimson Rambler*, *Celine Forestier*, and *La France*, the last named being very pretty; Mr. W. RUMSEY was 2nd in this class, but obtained 1st prize for a group of *Roses*, in which there were included some forty or more plants.

Mr. MOUNT, of the Canterbury Nurseries, won 1st prize for twenty-four cut *Roses*, showing in his usual excellent fashion; and Mr. W. RUMSEY, Joyning's Nurseries, Waltham Cross, was 2nd.

Mr. G. KELF, who took a 1st prize for six specimen *Palms*, showed very good plants indeed, including the following species:—*Chamaerops humilis* and *Fortunei*, *Phoenix rupicola*, *Livistona chinensis*, and *Areca lutescens*.

The only competitive groups of *Orchids* were staged by Mr. G. Cragg, gr. to W. WALKER, Esq., Percy Lodge, Winchmore Hill. They were composed of *Cattleyas*, *Lælias*, *Dendrobiums*, *Cypripediums*, and *Odontoglossums*. The *Cattleyas* included five plants in flower of *C. citrina*.

Forty-two zonal *Pelargoniums*, and twenty-four trusses of *Pelargoniums*, Messrs. A. W. YOUNG & CO., Stevenage Nurseries, won 1st and 2nd prizes respectively, showing the variety *King of Denmark*, a salmon-pink, semi-double-flowered.

NATIONAL AURICULA. (Northern Section.)

APRIL 30.—This body held its annual show in the large room of the Free Library, Middleton, Manchester, on the above date, when a very beautiful exhibition was got together of these very interesting plants. The weather unfortunately debarred good attendance, which is much to be regretted. The principal prize flowers showed good quality combined with high cultivation. Among the principal exhibitors were the Rev. F. D. Horner, Messrs. Lord, Simonite, and Beswick.

SHOW AURICULAS.

For six distinct, Rev. F. D. Horner 1st, Mr. T. Lord 2nd. The premier Auricula of the show was shown by Mr. Lord, with *Mrs. Henwood*, green-edged.

The premier Alpine Auricula, a prize for which was offered by R. Gorton, Esq., was shown by Mr. T. Lord, for his "Charles Turner."

For *Polyanthuses*, black grounds. For three dissimilar, G. Thornley 1st.

For three ditto, red grounds, J. Beswick 1st.

For single plant, black grounds, Geo. Thornley, 1st, 2nd, and 3rd.

For ditto ditto, red grounds, J. Beswick 1st, J. Greenhouse 2nd, and G. Thornley 3rd.

From Messrs. Barr & Sons, of Covent Garden, came a good collection of *Narcissus*, including many of the leading varieties; the same firm sent collections of *Primroses*, *Auriculas*, and many varieties of single and double Tulips. J. W. Bentley, Esq., of Castleton, sent some well-grown specimens of *Azaleas* and cut-flowers of *Aponogeton distachyon*, and also of *Wistaria* and *Rhododendrons*.

THE SCOTTISH HORTICULTURAL ASSOCIATION.

MAY 3.—This Association held a very successful and interesting meeting on the above date, in their rooms, St. Andrew Square, Edinburgh.

Among several exhibits on the table, including a brace of the finest spring Cabbages seen this year, were three fine blossoms of W. H. Lincoln *Chrysanthemum*, from Mr. P. HUNT, Coltbridge Hall; and several choice *Narcissi* from Mr. J. ALEXANDER, of Revesby Abbey, Boston, Lincolnshire. Among these were some fine examples of *Sir Watkin*, *Golden Spur*, *Incomparable*, a very blanché paper-white semi-double; *Orientalis*, *bicolor grandis*, &c. Mr. TODD, the president, also exhibited a beautiful blend of *Irises* and *Narcissus*, intermixed with *Smilax* and other foliage.

In the absence of the author, the Secretary of the Association, Mr. R. L. LAIRD, read Mr. Alexander's able paper. With a few sentences upon the large importations from Guernsey and the Scilly Islands, he went on to speak of the extreme usefulness and importance of *Daffodils* from trade and decorative points of view. We had no hardy or other flower that travelled better, kept so long or well, and produced better results in decorative arrangements. The demand for them was enormous, and it had been said that as many as 200 tons of flowers had arrived from the Scilly Islands in a day.

Mr. Alexander then proceeded to give a long account of the culture and treatment given to *Narcissus* by two of the best local growers, Mr. T. KINN, Marham-lo-Pon, near Boston, Lincolnshire, and Messrs. White & Sons, near Spalding. The latter have, perhaps, the better, that is the deeper soil, a point of considerable importance in bulb-growing; though that of Mr. Kinn has been greatly improved

by the additions of spent tan and other refuse. The Boston growers also plant in rows some 9 to 14 inches apart, while the Messrs. White seem to grow chiefly in 4-foot beds, the bulbs being planted from 4 to 6 inches asunder. Great care is taken to thoroughly clean the land of Couch, and to get it into good condition before cropping with bulbs. Soot and bone-dust are chiefly used as top-dressings, and their good effects speedily tell on the colour, strength, and width of the leaves, a point of much importance in these modern times, when, as our President, Mr. Todd, reminded us, the leaves of *Daffodils* have a special commercial value for decorative purposes.

The chief cultural points referred to were lifting the bulbs in July, or as soon as the leaves wither, and drying them off in *Potato* sprouting-boxes; that is, those used to green-seed or to start *Potatoes* in. Planting should be performed in August or September to ensure success. Great care should be taken to prevent the sorts being mixed, as, of course, there are wide differences in price between *Sir Watkin*, *Golden Spur*, *princeps*, *bicolor grandis*, &c., and such old sorts as *Butter-and-Eggs*, *Codlins-and-Cream*, and other old favourites, which we were pleased to hear were also grown in quantities. A cool store-room of considerable size is almost a necessity on every bulb farm. The long stalks of the *Narcissus* favour safe storage. Pails or tanks filled with water are latticed over with laths, and the stems of the *Narcissus* passed through into the cool water beneath. Here the flowers are safe from scorching winds and fierce sunbeams, and are within reach of the packers and bunchers, mostly women, who receive a halfpenny per dozen bunches, each bunch containing a dozen blooms. The bunches should have two ties of raphia-fibre. It is said that one woman will sort and tie 50 dozen bunches of twelve each, in a day; also, that she will tie 1000 bunches; also, that some 200,000 bulbs were needed to plant an acre, which in case of the finer sorts represented a large amount of capital. Nevertheless, though prices had ruled a little lower this year, there could be no question that bulb-growing paid well, and cases were cited of labourers and small holders who had made as much as £20 of their bulbs. It was also stated that some of the small holders had grown the finest bulbs.

At the request of the President (Mr. Todd), Mr. Fish made a few remarks on the vital importance of such home-industries as hardy bulb-growing to the happiness and prosperity to our rural classes; and Mr. Alexander Mackenzie of the Warriston Nurseries moved a hearty vote of thanks to Mr. Alexander, who had once been in these nurseries, which was heartily carried.

THE GREAT QUINQUENNIAL MEETING AT GHENT, as described by two gentlemen from Edinburgh. At the close of the meeting of the Scottish Horticultural Association on the "Culture of Hardy Bulbs," the President asked Mr. J. P. LAIRD, one of the judges at Ghent, and Mr. ALEXANDER MILNE to give a few personal impressions of the great show. Mr. LAIRD began with a graceful testimony to the British Horticultural Press for its copious reports of the great show. As to Ghent, the show is looked upon as the great national festival, in which the whole nation, from the King of the Belgians to the poorest of his subjects, participate. We get Royal patronage for horticulture in England, but it would somewhat astonish us to have to meet the Queen or the Prince of Wales at 8 A.M. at our great flower show, or to have either spend three hours in our biggest and best shows. But then in Ghent, horticulture is a national industry. The chief exhibition building is a permanent Hall of Horticulture, and the mere annexes are superior even to the Waverley Market. There were some 700 separate classes, and the special list of this fourteenth great exhibition, which Mr. Laird held in his hand, formed quite a book. The area of the exhibition covered some 3 acres, and there was, it was said, some 19,000 plants exhibited, 1500 of them being *Azaleas*, some of the latter some 8 feet in diameter. As there were nine lots of *Azaleas* shown of sixty plants each in thirty varieties, a vivid picture of the magnitude and grandeur of the great show of Ghent may be obtained.

With a vivid description of the cosmopolitan character of the jurors, who, if not collected from Persia and Peru, came from Brazil, Japan, England, Scotland, France, &c., and of the new plants noticed in the *Gardeners' Chronicle*, and with a pathetic reference to Louis Van Houtte and Mr. Linden's memorial plants, probably a hundred or more, Mr. Laird concluded his all too-brief description with an eloquent testimony to the Ghent Exhibition as an object-lesson of great value to us in the culture of hard-wooded plants, which seemed in danger of becoming a lost art in Scotland.

Mr. MILNE confined his remarks to the nurseries of Ghent and Bruges, and specially dwelt upon the enormous amount of glass, and the concentration of business energy on a few specialties. One of 2 or 3 acres of glass grew chiefly three things—*Palms*, *Araucarias*, and *Sweet Peas*. The Messrs. Sander of St. Albans are said to have many acres under glass in their nurseries at Bruges, visited by Mr. Milne. One nursery with several acres of glass was said to be worked with twenty-two men. But then the hours are much longer than in Britain, and the wages much lower.

Truly there are more object-lessons than the improved culture of hard-wooded plants to be learned at Ghent and Bruges, and one of them undoubtedly is the longer leisure and equal or superior opportunities offered to Scotch, English, and Irish gardeners to master, so far as may be possible, the science and practice of horticulture to those offered to their foreign rivals or competitors (1). D. T. Fish.

PLANT PORTRAITS.

CHIRONOMODA LUCILLE, SARDENSIS, *Florilegium Haartemense*, t. xviii.
 HYACINTH, KING OF THE BLUES, *Florilegium Haartemense*, t. xvi., raised by Van Velson, introduced 1866.
 IRIS STYLOSIA, *Bull. Soc. Toscan.*, t. i., 1898.
 PEAR BUTIRRA D'HARDENPONT (Bourré d'Hardenpont), *Giovale d'Agricoltura*, t. ii., 1898.
 PEAR TRIOMPHE DE VIENNE, a Pear raised at Vienne, in S. France, September and October.
 PLUM MYROBALAN, *Bulletin d'Arboriculture*, &c., April.
 ROSE CAPRICE DE VICK, *Moniteur d'Horticulture*, May.
 SCILLA SIBERICA, *Florilegium Haartemense*, t. xviii.
 TILLANDSIA LINDENI TRICOLOR, *Revue Horticole*, May 1.
 TULIP: 1, La Reine, white; 2, Gele Prins (Yellow Prince); 3, Zilveren Standaard, white with red stripes, *Florilegium Haartemense*, t. xvii.

ANEMONE ST. BRIGID: *H. H., Carlisle*. This "The Irish Anemone," is a fine large-flowered variety of the single flowered Anemone coronaria.

ASPARAGUS: *W. C. L.* A very fine sample—could scarcely be finer, or consist of more edible portion.

BLACK CURRANTS: *W. W. H.* Infested with the mite. Cut off and burn all affected shoots, and if the entire bush is affected similarly, dig it up, and burn. There is no known cure, and total destruction is the best policy.

BOOKS: *J. B.* *The Tomato: its Culture and Uses*, by W. Iggulden, office of *Journal of Horticulture*, 12, Mitre Court Chambers, Fleet Street, E.C. Price, 1s.

CARNATION AND ROSE: *Wilts.* The first is affected by *Helminthosporium echinulatum*, as you suspect. There is no known cure, but you might keep the fungus from attacking sound plants by occasionally dressing them with sulphide of potassium $\frac{1}{2}$ oz. to 1 gallon of water. Burn the diseased plants forthwith. The Rose is affected by the Orange-rust. Cut off and burn affected shoots, and apply flowersulfur to the bushes when wet with dew or rain.

CHRYSANTHEMUM LEAF-MINER: *X.* Remove the leaves as soon as attacked, and syringe the plants with Quassia-chip solution, or fumigate them with a view to rendering them distasteful to the mature insect.

CHRYSANTHEMUM RUST: *B. P.* Apply sulphide of potassium $\frac{1}{2}$ oz. to the gallon of water occasionally.

CHRYSANTHEMUMS: *W. Brown.* The leaves are affected by rust. Apply sulphur, a mild form of the Bordeaux Mixture, or sulphide of potassium $\frac{1}{2}$ oz. to 1 gallon of water. We fear you do not read your *Chronicle* attentively.

DOUBLE-FLOWERED BERBERIS STENOPHYLLA? *W. A.* Your plant is more like *D. Darwinii*; but, as you know, all sorts of varieties come from hybrid seeds.

EUPHARIS: *B. P.* When growing keep the plants in a very moist atmosphere, syringing them two or three times a day, and during the resting period omit the syringing and do not afford much water, only affording it to prevent wilting. If Eupharis are syringed often daily when growing, water need not be afforded with the water-can. The temperature for growing plants, and at such times as the plants are forced into flower after a rest, should, at night, be 65°, and by day 75° to 80°; at other times 60° to 70° are suitable.

GLOXINIAS: *B. P.* Do not syringe the plants at any time.

HYMENOCALLIS: *Contich.* *Hymenocallis ovata* and *H. galvestonensis* much resemble one another in the flowers, but the former has an oblong leaf 4 to 6 inches broad, narrowed gradually to the base, and the latter a linear leaf not more than an inch broad. *J. G. B.*

INSECTS: *Grantham.* Caddis-worms; larvæ of insects of the order Trichoptera, sometimes injurious to aquatic plants. *R. McL.*

INSECTS IN MUSHROOM-BED: *W. C.* The insects sent are Uropoda, but being immature, the species cannot be identified. Lime and soot or petroleum emulsion might stop them. There is, however, reason to suppose the insects do no damage to the Mushrooms, but rather feed on other things that

do; but the food of Uropoda is not really known with certainty. *A. D. M.*

LEATHER JACKETS: *Harrobian.* The insect has been named, and remedies given, on several occasions lately. Consult previous issues.

MAIDENHAIR FERN: *B. P.* Not to syringe the plants is the safer practice.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*W. Cooke.* *Leucjum æstivum*, Summer Snowflake.—*W. Brown.* *Euonymus radicans aureo-variegata*, a prostrate form of *E. japonicus*. It is a good hardy rockwork plant.—*S. S.* The plant was known as *Browallia Jamesii*, but its name up to date is *Streptosolen Jamesii*.—*C. J. H.* We cannot undertake to name varieties of florists' flowers.—*T. T., Nuneaton*, 1, *Serapias cordigera*; 3, *Ophrys apifera*; 4, *Aceras anthropophora*; 5, *Ixia odorata* (erecta); 6, *Bartholina pectinata*.—*G. P.* *Cyrtomium caryotideum*; 2, *Polypodium glaucum*; 3, *Dictyogramma japonica*; 4, *Davallia Tyermani*; 5, *Davallia bullata*; 6, *Caragana arborea*; 7, *Davallia tenuifolia*; 8, *Cyrtomium Fortunei*; 9, *Adiantum macrophyllum*.—*J. L.* *Coelogyne lactea*.—*C. A. B.* 1, *Begonia corallina*; 2, *Agathæa cœlestis*; 3, *Eupatorium Weinmannianum*; 4, *Aspidium (Neprodium) molle*; 5, *Saxifraga sarmentosa*; 6, *Polystichum coriaceum capense*.—*E. T., Ashford*, 1, *Orchis* (next week); 2, *Buddleia globosa*; 3, *Kerria japonica flore pleno*.—*W. J.* 1, *Schomburgkia tibicinis*; 2, *Dendrobium Devonianum*.—*W. C. F.* 1, *Spiræa betulifolia*; 2, *Cryptomeria elegans*; 3, *Prunus Palus*; 4, 5, and 6, varieties of *Rhododendron arboreum*, or hybrids of it.—*A. C. C.* A form of *Narcissus calathinus*; perhaps a cross between that species and some other.—*J. B.* 1, Double Cherry, Waterer's variety, pink; 2, Double Cherry, Waterer's variety; 3, *Arundinaria japonica*; 4, *Scirpus sylvaticus*; 5, *Skimmia japonica*; 6, *Scilla hispanica*.—*Crewe.* The yellow flowered is *Saxifraga aizoides*; the white one *S. hypnoides*.—*J. E.* *Asclepias curassavica*.—*A. B. S.* From the condition in which the fungus reached us, we are unable to name the same.

NARCISSUS: *J. G.* Fasciation is by no means uncommon in these plants.

NEW ODONTOGLOSSUM-HOUSE: *Enquirer.* If the adjoining house is also used for the cultivation of *Odontoglossum*, can you not attach the new one to it, have a saddle-roof, with wide guttering between the two to receive the rainfall, doing away with the dividing wall, and merely furnishing piers or oaken posts to support the two roofs at the point of union? The bricks obtained from the discarded wall will do to build the outer walls of the new house. Sufficient ventilation can be obtained by making openings in the walls, furnishing these with louver board shutters, and by means of ventilators in the roof.

NYMPHEAS: *J. G. W., Isle of Rum.* The Marliac varieties will live and thrive in an open tank in your district, provided it be placed in a warm position, say, against the wall of a hothouse, and wholly sunk in the ground. The roots may or may not be kept under water during the period of rest, that is, if they are grown in flower-pots, and therefore portable.

PALM LEAF AND SCALE INSECTS: *E. C.* Palm-leaf is infested with the Thread-scale (*Iscnaspis filiformis*, Douglas). You cannot remove the scales at once without injury to the leaves; but you can destroy the insects by applying any of the insecticides in general use, giving two or more applications at intervals of ten to fourteen days. After a time the scales will naturally come away from the plant. The scales hold on very firmly, and being insoluble in potash, are difficult to remove. *G. N.*

PEACHES FALLING OFF: *G. McK.* Too thickly cropped. The growth is in excess of the nutriment, or what comes to the same thing, the nutriment cannot get to the fruits in sufficient quantities at the right time, hence the failure.

PEACH-TREE GUMMING: *Beginner.* The Peach twigs sent show "gumming." The young twigs become discoloured just under the bases of the leaves, and the patches rapidly extend. The cambium or growing part of the twig shows a breaking-down into a brownish gum, which spreads through neighbouring parts and causes the discoloration and collapse seen from the outside. No fungus or

other cause can be found. The whole question of "gumming" of fruit trees has been often discussed, but no satisfactory reason for it has yet been given, though fungus (*Ascophora Beijerinckii*) and bacteria are suspected. Defects in cultivation certainly produce the disease, and in the present case the much shaded position of the house seems a sufficient explanation. Internal heat without all the sunshine we can get in this country can never produce healthy growth. It will probably lead to insufficient hardening of last year's wood, and a deficiency in the food material; the foliage and fruit will utilise all available food, while the new internal stem-tissues starve and break-down into a gummy substance. Certainly more sunshine is necessary if everything is to go well. Reducing the fruit-crop would also help to give other parts a share of food-material. For the present, discoloured twigs should be pruned off, this will relieve the tree of what can never be healthy twigs. *W. G. S., Leeds.*

PEAR LEAVES: *S. R.* The leaves are affected with mite, *Phytoptus pyri*.

PEAT MOSS MANURE: *Humulus.* A recommendable manure for heavy land, provided it has been kept under the animals so long as it is capable of absorption. We should suppose it to be richer in plant food than spent hops.

PELARGONIUM SEEDLING: *J. B.* So far as we can judge from the truss of flowers which were shedding on arrival here, your variety is a very fine one. Send it to a large grower of Pelargoniums, or submit it to the Floral Committee of the Royal Horticultural Society. In either case it would be necessary to send the plant or several specimens, so that its general habit of growth and flower may be seen.

SCALE INSECTS: *S. R.* The Apple-scale (attacking, however, many plants) *Mytilaspis pomorum*. It has nothing whatever to do with the San José scale.

SEEDLING CANNAS TURNING BROWN AT THE EDGES OF THE LEAVES: *B. P.* There may have been a check given in transferring them from the propagating-house to the warm greenhouse, or cold-water afforded, or cold draughts have struck them, or many things; you give us no clues.

SPENT HOPS: *Humulus.* When mixed with stable-dung they ferment readily, and make, when decayed, a good manure for vegetable cultivation. The Hops, if in large quantities, heat strongly, but do not so readily decay as when combined with litter. If the stench arising from their fermentation were not so offensive, Hops would make lasting materials for hot-beds.

TOMATOS: *J. B.* Your plants are affected with a fungus (*Cladosporium*). Burn the affected plants, and syringe the healthy ones with sulphide of potassium, half-ounce to one gallon of water.

TULIPS: *E. C. E.* 1, near to *T. chrysolora*; 2, form of *T. fragrans*. It will be better to send them to some large grower, as we cannot name them with certainty.

VINES: *Grape.* 1, over-feeding—more nutriment than the plant can digest in the time; 2, scorching.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED,

and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, AND ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Markets and Weather, see p. x.)

THE

Gardeners' Chronicle.

SATURDAY, MAY 21, 1898.

THE WEEPING WILLOWS.

THESE trees may be divided into two groups, the first being those which (like *Salix babylonica*) naturally grow into large trees with a pendulous habit, whereas the second (like the so-called American Weeping Willow) are really low or prostrate shrubs, made into small weeping trees by grafting on standards. The former are, of course, the more important as material in the landscape-gardener's hands; but the smaller ones, too, are very pretty. Nowhere do the Weeping Willows look so well as in their natural position near water, where the graceful lines of *S. elegantissima*, *S. alba pendula*, and *S. babylonica* are especially telling. With regard to *S. babylonica*—and, indeed, all other trees of unusual habit or colour—a certain reserve must be maintained in planting it. It is not a tree that should meet the eye at every turn. There is about it a suggestion of excessive sentimentality, which, like the real thing, becomes wearisome if too frequently repeated. It is, I think, as an isolated tree, rather than in immediate association with other trees, that the Weeping Willow is seen to best advantage.

S. babylonica, *S. alba*, and the varieties and hybrids belonging to them, can easily be increased by cuttings, and reach their full size without artificial aid. *S. cordata pendula* can also be propagated in the same way, but has to be trained up to the required height. All the others mentioned are best worked on tall stems, and the Goat Willow (*S. caprea*) is as good a stock as any for them.

S. babylonica.—This is, of course, the most popular and typical of all the Weeping Willows; and although it could not have been known to Shakespeare, no Willow recalls more aptly the music of his words—

“There is a Willow grows aslant a brook,
That shows his hoar leaves in the glassy stream.”

Anyone who in summer time has travelled up the Thames from Richmond to Sunbury will have noticed how much of the beauty of the riverside is due to this tree. There is no doubt that the first English specimen of *Salix babylonica* was grown in this neighbourhood. A story used to be current that it originally came from Spain, a present, it was said, sent to Lady Suffolk from that country in a basket; and Pope, who was present when it arrived, noticing that some of the twigs of the basket were alive, had one rooted, which eventually grew into a celebrated tree at Twickenham. This may be true so far as that particular specimen is concerned, but it rests only on newspaper authority, published in 1801. An earlier and more authentic account of its first introduction was found in the manuscript notes of Peter Collinson, many of which were published in the tenth volume of the

Transactions of the Linnean Society. Collinson there observes that “Mr. Vernon, Turkey merchant at Aleppo, transplanted the Weeping Willow from the River Euphrates, brought it with him to England, and planted it at his seat at Twickenham Park, where I saw it in the year 1748. This is the original of all the Weeping Willows of gardens.” The species has long been cultivated in the temperate parts of Europe and Asia. It does not appear ever to have been found in an undoubtedly wild state, but is most probably a native of China. It attains a height of from 30 to 50 feet, and always succeeds best where there is abundant moisture.

S. b. var. annularis (syn. *crispa*) is very distinct, its leaves being curiously twisted, or even spirally curled. It must rank as a curiosity rather than as a handsome tree, for it is neither so graceful nor so vigorous as the type.

Salix Salomoni.—By some authorities this Willow is made a variety of *S. babylonica*; by others it is thought to be a hybrid between that species and our native White Willow (*S. alba*). Compared with *S. babylonica*, it is not so distinctly pendent in habit, but is of much sturdier growth. According to some experiments recorded in one of the last numbers of *Garden and Forest* (vol. x., p. 496), it proved in a young state to be the fastest-growing of all the Willows. Stems cut back to 2 feet from the ground at the Chico Forestry Station, California, in February, 1896, were, in August, 1897, 31 to 32 feet high. Its young branches are yellowish-green, and the long, narrow, lanceolate leaves are bluish-green, beneath, and, indeed, very like those of *S. babylonica*.

S. elegantissima.—This is another Willow whose origin is not certainly known. Some authorities have considered it to be a hybrid between *S. babylonica* and *S. fragilis*, and this appears to be the most probable origin. Being harder than *S. babylonica*, it is a useful Weeping Willow for climates too cold for that species, and although it lacks its peculiar grace, it is a very elegant tree. It is of more spreading growth than *S. babylonica*, and takes after *S. fragilis* also in the leaf, which is larger and broader than in the other species reputed to be its parent, and quite glabrous. *S. elegantissima* may be described as intermediate between the *S. blanda* next described, and *S. babylonica*.

S. blanda.—The origin of this Willow is thought to be the same as that of *S. elegantissima*, viz., *S. babylonica* × *S. fragilis*. It may be easily mistaken, indeed, for *S. elegantissima*. It differs, however, in its even more vigorous growth, its broader, more glossy green leaves, and its less purely pendent growth, being, in short, altogether a nearer approach to *S. fragilis*. It is capable of bearing a greater degree of cold than is *S. babylonica*.

S. alba var. pendula.—From *S. babylonica*, the White Willow is in all its forms to be distinguished by the silky covering on both sides of the leaf. Even in its typical form it is a very graceful tree, with its slender, pendent twigs; but this character becomes more marked in the variety *pendula*. There is also a weeping variety of the Golden Osier (*S. vitellina* or *S. alba vitellina*), in which the young shoots towards the latter part of the year become a rich yellow colour. Both these grow into tall trees.

S. caprea var. pendula (The Kilmarnock Willow).—The weeping variety of the Goat Willow is well known in gardens. Like the type, it flowers in early spring on the leafless branches, and is then very handsome. The leaves are dark green above, and clothed beneath with a thick white wool; they are, moreover (with those of the type), perhaps the largest among all the Willows. The branches of the Kilmarnock Willow are perfectly pendent, but stiff and sturdy. It is a useful plant where there is no room for the bigger Weeping Willows. It is usually grafted on standard-stems of the common Goat Willow.

S. purpurea var. pendula.—In gardens this is oftenest known as *S. americana pendula* (the

American Weeping Willow), an unfortunate name, as *S. purpurea* is an Old World species. It is grafted on standards of *S. caprea*, and makes a very handsome weeping-tree. The leaves are linear, narrowest towards the base, and borne on long slender twigs, and the tree, as a whole, is more graceful than the Kilmarnock Willow.

S. purpurea var. Scharfenbergensis appears in the continental catalogues; it is said to be superior to *var. pendula*.

S. repens var. argentea.—A commoner name for this when grafted on standards is *S. sericea pendula*. It is really a variety of the common *S. repens*, with oblong leaves from $\frac{1}{2}$ inch to 1 inch long, and beautifully silvery and silky beneath. Grown on standards it is quite a pretty weeping bush, perhaps the most charming of these dwarf kinds. Both type and variety are natives of Britain.

S. cæsia var. Zabeli pendula.—In nurseries one meets with this under the name of *S. Zabeli pendula*, but Mr. Nicholson has referred it to *S. cæsia*—a determination also arrived at by the continental botanists. When worked on standards it makes a handsome weeping tree of low growth. The leaves are obovate or oval, 1 to $1\frac{1}{2}$ inches long, and of a bluish-green colour. *Salix cæsia* is a native of middle and south-west Europe.

S. cordata var. pendula.—There are several varieties of *Salix cordata* in cultivation, the most notable of which perhaps is the *var. rigida*. The present Willow is really a more pendulous form of that variety, and is commonly called *S. rigida pendula*. It has the same large lanceolate leaves (measuring 4 to 5 inches in length), with a cordate base and large stipules; and they are of a bright glossy green above, glaucous beneath. This and the ordinary variety *rigida* are amongst the handsomest of North American Willows. W. J. Bean.

NEW OR NOTEWORTHY PLANTS.

PASSIFLORA IM THURNII, sp. nov.*

THE illustration we give at p. 307 shows one of the handsomest Passion-flowers we have yet met with. It was discovered by Mr. Everard Im Thurn in British Guiana, and to him we are indebted for the opportunity of examining it. It is a climbing plant, with broadly oblong acute, leathery leaves, glabrous on the upper surface, setulose below; the erect (not pendulous) flowers are between 4 and 5 inches in diameter, the sepals broadly oblong glandular at the margin, and of the “most brilliant scarlet colour, the petals are rather smaller, rose-coloured, whitish at the base when dry [purest white in the fresh state]. The plant is near to *P. glandulosa*, but is quite distinct from any other, on which account we append a technical description. Mr. Im Thurn, who speaks of it as one of the finest things he ever saw, has it in cultivation in his garden;

* *Passiflora Im Thurnii*, Mast., sp. nov.—Scandens cirriferâ, ramis herbaceis gracilibus teretibus striatis; foliis circa 16 cent. long., 9 cent. lat., subcoriaceis superne glabris, subtus præcipue secus nervos, setulosis cordatis 1-nerviis oblongo ovatis acutis apiculatis; petiolis 2 cent. long., antice glanduloso-incrassatis; stipulis caducis; pedunculis, quam petiolis 2–3-plo longioribus ascendentibus simplicibus 1-floris versus apicem articulatis bracteisque tribus parvis instructis; floribus erectis 12 cent. diam.; tubo late infundibuliformi fere 2 cent. long., 15 mill. lat., extus glabro intus longitudinaliter striato; sepalis 5 cent. long., 12–13 mill. lat., intense coccineis, crassiusculis oblongis obtusis extus ad margines glandulis circularibus remotis onustis; petalis sepalis parum brevioribus angustioribus tenuioribusque pallide roseis intus versus basin candidis; corona fauciali duplici, serie externa e filis crassiusculis rugosis circa 1 cent. long. constante, serie interna duplo longiore basi membranacea tubulata superne contracta et in lacinias breves divisa, corona infra mediana fere ad basin tubi sita membranacea conica tubulata superne lacinata versus gynandrophorum inflexa; corona basilari brevi annulari membranacea basin gynandrophori cingente; gynandrophoro petalis parum brevioribus longioribus 5 angulatis; filamentis complanatis oblongis; ovario ellipsoideo puberulo stylis 8 basi sejunctis superato; stigmatibus clavato-dilatatis. Ex spec. exsiccato. M. T. M.

Brit. Guiana. E. Im Thurn.

and it is to be hoped that so gorgeous a plant may soon be introduced into this country.

Mr. Im Thurn favours us with the following additional particulars relating to the plant:—"The red-and-white Passion-flower which I sent you a few weeks ago was collected by me in British Guiana, at very little above sea-level (perhaps 150 feet), but some distance in from the coast. I have been making a road from the Barima to the Barama River, through the virgin forest, over rocky, half-sandy, half-clayey ground. Where we cleared the trees, the usual crop of weeds sprang up in a few months. This weedgrowth was largely composed of an arborescent *Solanum* (*S. Demararensis*), and various species of *Heliconia*, but among these were a good many creepers, such as *Mikania*, *Aristolochias*, and *Passifloras*. Of the latter, my red-and-white one was by far the most beautiful, a really very striking thing, and was the only one which was new to me. I took plants of it, and have these growing in my garden, but have not as yet succeeded in getting seed. Another Passion-flower which was growing in the same place was the *P. pruinosa*, which was described in the *Gardeners' Chronicle* a few months ago (see p. 401, vol. xxii., N. S., 1897), and of which I sent Messrs. Sander & Co. seeds, from which that firm has contrived to raise a stock of plants. *Everard F. Im Thurn.*"

ORCHID NOTES AND GLEANINGS.

ANGRÆCUM LEONIS.

THIS interesting plant is just now flowering very freely at the nurseries of Messrs. R. Veitch & Son, Exeter. Several plants are gay with their distinct blossoms, and add a peculiar charm to the ordinary occupants of the house. Grown in baskets in a house where *Cœlogyne cristata* in large numbers, *Cypripediums*, *Anthuriums*, &c., are well done the temperature is usually at about what one would consider intermediate. The house is span-roofed, running north and south, and as it was erected a good number of years ago, the usual practice then of wooden sashes and small squares of glass cause the house at midday to have very little need of blinds, though there is plenty of light; as the sun gets round to the south-west by 4 o'clock, a sharp heat can soon be run up, but the sun's rays then are not at all injurious. I notice one plant of this *Angræcum* with nine perfect leaves in the best of health, another with eight, and a third with seven leaves; each are flowering, one having six perfect pure white blooms, with just a slight shade of green on the column. The sweet scent observable with this, which is strongest at eventime, is doubtless a provision of Nature for the attraction of insects, who come for a taste of the nectar contained in the spur; also most helpful in the due fertilisation of the blooms.

Beside the more showy, such as *A. sesquipedale*, *articulatum*, *Sanderianum*, *eburneum*, &c., two very interesting species not at all difficult to grow are *A. Scottianum*, with terete leaves and elongated stem, having large, pure white flowers, with a spur several inches long of a pale yellow colour; and *A. pellucidum*, with bright shining leaves a foot or more in length, and producing long spikes of small white flowers, very delicate and transparent, and fragile as a thin plate of glass. The spikes, a foot to 18 inches in length, are densely covered with blooms, and when placed in close proximity to others of the same genera, shows great distinctness and diversity. Perhaps it were better if this latter were always known by the other generic appellation, *Listrostachys pellucida*. *W. Swan, Exmouth.*

CATTLEYA CITRINA.

This beautiful species, known to the natives of the region it inhabits in Mexico as *Corticoatzontecoxochitl*—a terrible name for a very beautiful flower—has been in gardens for upwards of sixty years. While it is grown well by certain cultivators, others have had little success in its cultivation. It is therefore a pleasure to us to record instances of success. Sir

Chas. Strickland, Bart., of Malton, Yorkshire, whose plants were figured in the *Gardeners' Chronicle*, grows it so easily as to cause him to wonder why so many fail; so also J. T. Bennett-Poë, Esq., of Holmewood, Cheshunt, and some few others. Now comes one of the largest and most intensely-coloured yellow flowers of it which we have seen, sent by Mr. A. Chapman, gardener to Captain Holford, Westonbirt, Tetbury, who gives the information that the plant has been grown in the Westonbirt collection for upwards of twelve years, and always possesses flowers superior to those of ordinary varieties. All the segments are broad, the petals especially so, and the whole flower of very thick wax-like substance, and like others of the species very fragrant. The cause of failure is in most cases probably due to the plants being kept too warm and close after the growths are completed.

ODONTOGLOSSUM CRISPUM ROSEUM.

A first inflorescence of a beautiful form of the *O. crispum roseum* section, far superior to the original, is sent by Captain Holford, Westonbirt, Tetbury. It is of the best type, with broad segments, and represents a perfect florist's flower according to the ideas prevailing among fanciers of *Odontoglossums*. The petals are fringed, and the flowers almost entirely of a warm purplish rose colour, on which some small red-brown spots appear. A really fine form of this class is even more rare than are the blotched forms which command such high prices, and is certainly equally beautiful.

ODONTOGLOSSUM HALLI VARIETIES.

Flowers of a very remarkable series of varieties of *Odontoglossum Halli* are furnished by Joseph Broome, Esq., of Llandudno, who remarks that, though beautiful, single flowers give no idea of the handsomeness of the tall, arching flower-spikes as seen in the Orchid-house. Primarily there were two distinct types, the white-lipped, and that in which the ground colour is of a yellow colour. Of the former one resembles *O. H. Lindeni*, and of the latter several are fine forms of the *O. H. magnificum* section. In each there is variation, but all have broad petals, and segments spotted with rich brownish-red. Among the very marked variations is one with long, narrow segments, very darkly coloured, having a narrow, apiculate lip, with reddish spots down the middle, and a singular-looking spiny crest. It seems a variety of *Odontoglossum chaetostroma*, Reich. f. (*Gardeners' Chronicle*, 1883, i., pp. 562, 592). The plants were of Consul F. C. Lehmann's collecting, in Ecuador.

ORCHIDS AT BARONS HALT, TWICKENHAM.

Henry Little, Esq., may be reckoned among our oldest amateur florists and Orchid-growers. Formerly, when resident at Hillingdon, he improved the strains of *Primula*, *Cyclamen*, *Pelargonium* (both zonal and show), *Amaryllis*, and various other flowers, all of which he cultivated well, and frequently exhibited. At the same time a collection of Orchids formed one of the chief attractions to his gardens, and until a few years ago he was a successful exhibitor of these plants. Showing was then abandoned, but the collection has continued to be enriched by the best varieties procurable of the showier species of Orchids, until at the present time it contains many specimens, some of which are unique.

Cattleyas and *Lælias* make up the greater proportion of the species cultivated, and of these the collection of selected varieties of *Cattleya Mendeli* is making a grand show. Some very large and richly-coloured varieties are in bloom, the largest of them being *C. Mendeli* Dorothy Little, a grand flower of 10½ inches across; and *C. M. grandis*, a flower of very fine colour and proportions. Some of the varieties have very broadly-expanded lips, which are frilled at the edge; and one distinct form has a bluish white veining running through it, while another has pure white sepals and petals, and vivid carmine-crimson lip.

With the *C. Mendeli*, some good are in bloom of forms of the fragrant *C. Schroderæ*, of *C. Schilleriana*, *C. Skinneri*, and a superb form of *C. Skinneri alba*, which seems to have larger flowers than the type,

and to be of a different stamp to the ordinary forms of *C. Skinneri alba*; *C. intermedia*, and others. Showing well for bloom are several good specimens of *Cattleya Mossiæ*; and remarkable for fine culture is a batch of very strong *C. Bowringiana*, which is a plant Mr. Howard, the Orchid-grower, finds very easy to grow, but requiring great care to prevent water lodging in the young growths until they at least get well up. A fine batch of selected varieties of *C. aurea* comes next, and here Mr. Little's plan of recording his fine varieties by drying the flowers in a book, which by the accompanying index renders examination of them easy, is at once apparent. Some curious variations, especially in the colouring of the labellums, was shown, some of them being almost wholly of a rich orange, with a few purple markings, while in others the purple predominated, and the orange was confined to the veining. *Cattleya labiata Warneri* grows well, and flowers profusely here, even the small plants sending up flower-sheaths, and one of the large specimens bears annually from twelve to twenty magnificent flowers. One of the reasons for the floriferousness of this and other *Lælias* and *Cattleyas* is, that the plants are exposed to the sun pretty freely, care being however taken to guard against burning.

Lælia purpurata is beginning to give evidence of what will be a magnificent show, for all are sending up flowers, and they consist of a few very large and richly-coloured varieties. But one of Mr. Little's favourites is his variety of *L. p. Schroderiana*, a large white flower, with but a little colour on the lip, and very fine purple tracing in the throat. *Lælio-Cattleya × elegans* and *L.-C. × Schilleriana* have been collected for years whenever a fine variety could be obtained. A few are in flower, the best being *L.-C. × elegans Littleiana*, which is grand in form, and of a dark ruby-purple colour. Of other remarkable things in bloom in the intermediate-house is a noble *Cattleya Lawrenceana*, with seven richly-coloured flowers on a spike; some good examples of *Dendrobium thysiflorum*, of which the tall-growing *D. t. Walkerianum* is a fine show-plant; *Lælia Latona*, *Epidendrum Wallisii*, and other showy species.

Planted out in a warm corner are numbers of plants of a noble form of *Vanda teres* with very large, and beautifully-marked flowers, which the plants are sending up profusely. With them are several plants of white *Vanda teres* obtained from different importations, and a very singular species imported as *V. teres*, but which has a flower botanically distinct from it, if it retains the form seen in the first bloom. The rare hybrid *Vanda × Miss Joaquim*, and also *V. Hookeriana*, which has been cross-fertilised, grow and flower in the most satisfactory manner.

Among the *Cypripediums* in flower are the curious natural hybrid, *C. × Littleianum*, imported with *C. tonsum*, *C. villosum aureum*, *C. Curtisii*, *C. × superciliale*, *C. × selligerum majus*, *C. Chamberlainianum*, a batch of good *C. exul*, *C. Druryi*, &c., and with them are a few *Phalænopsis*, which here, as in some other places, are the least satisfactory plants, although at Hillingdon Mr. Little grew them very well.

In other houses are prominent a finely-bloomed batch of plants of *Odontoglossum citrosimum*, some of *Miltonia Roezli* and *M. vexillaria*, and in a cool lean-to grand specimens of *Cymbidium Lowianum* are making a grand display of bloom, all being of good quality, two of the varieties very remarkable for the large size, and rich colour of the flowers. A nice plant of *C. Tracynum* is in the same house, and one or two more of it are expected to be among unflowered plants. One house contains a fine batch of *Cœlogyne cristata*, and a grand specimen of *C. c. alba*, and in others are many examples of good culture.

The whole place is interesting, and it is called Barons Halt because the site of the gardens has been identified as a camping-place of the Barons on their way to the signing of the Magna Charta. Like so many Orchid lovers, Mr. Little prefers bulbs and herbaceous perennials, instead of bedding plants in the open garden, and a fine display has been made with thousands of *Narcissus* and *Tulips*, which will be followed by *Pæonies*,

Delphiniums, Iris, &c. Adjoining the house and conservatory Mr. Little has constructed a fine suite of luxuriously furnished studios and retreats, which are filled with interesting pictures of his Orchids, taken by himself, and of mementos of travels in Algiers, Italy, and other places.

CULTURE AND VARIATION.

My attention has recently been called to a work published some time since by the Rev. G. Henslow, entitled *The Origin of Plant Structures by Self-adapta-*

the middle of the century, precisely because it began then to be found that our wild Ferns, which grow in such profusion in our western counties, and are sparsely or abundantly existent all over the British Isles, were peculiarly liable to "sport," i.e., vary, such variations often greatly enhancing the natural beauty of the plants, or adding curious though constant features quite alien to the normal plan. As time went on, a number of persons of high and low social position made a hobby of the quests and collection of these forms, and eventually not only were forms of greater abnormality and beauty obtained by selected

closely resemble each other to be discriminated. The figures given show, therefore, a large majority of wild finds, and there is ample evidence existing that the record is reliable. This may then be considered in the first place as fairly good evidence that variation does occur in wild plants, and the only thing that remains to demonstrate is that this variation is indiscriminate (or indefinite) in order to give Darwinism another chance. Here the first difficulty is to define indiscriminate, but I presume in this connection is meant variation, which does not arise through self-adaptation to the environment, but to all appear-

FIG. 114.—PASSIFLORA IM THURNII: COLOURS OF THE FLOWERS SCARLET AND PURE WHITE. (SEE P. 305.)

A, Longitudinal section of flower and ovary, nat. size; B, Anther, magnified; C, Sepal, nat. size.

tion to the Environment. In this a quotation is made from a private letter of the late Professor Romanes to the effect that "if you could prove that indiscriminate (i.e., indefinite) variations have not occurred in wild plants, but only under cultivation, you would destroy Darwinism *in toto*," and it is endeavoured to prove this by the evidence put forward. Now, as regards this particular question of variation, and wide variation under perfectly natural conditions, i.e., altogether apart from cultural influences or artificial environments, there is probably no better evidence existing than that collected by British Fern specialists during the last thirty or forty years. This particular branch of plant biology became highly popular about

culture; but in these later days combinations have been produced by crossing which have finally disposed altogether of the once vexed question as to the capability of cryptogamic plants being crossed or hybridised. This branch of the subject comes, however, under the head of culture, and is, therefore, to some extent, outside my theme, but not altogether so, for notwithstanding all the efforts of the cultivator as compared with those of the hunter for purely wild varieties, the latest catalogue of known varieties (Mr. E. J. Lowe's) records no less than 1119 wild finds out of 1859 varieties described, to which former number must be added many varieties which have been repeatedly found, and too

ance quite arbitrarily. Assuming this, it may be pointed out that very densely crested Ferns, such as *A. f. f. acrocladon* and other marked sports of same class, are heavily handicapped by two factors, viz., the cresting detracts from their height, rendering them extremely liable to be overgrown as seedlings, and hence ousted out of existence by their robuster normal companions; and secondly, the crests are extremely liable to be broken down by rain accumulating therein, and this, of course, is, in the long run, another disadvantage. A heavily-crested *Athyrium* found by the writer in Ireland had evidently been dwarfed so much by this process that it was only a few inches high in a spot where the

normal form was robust; it was much broken when found, evidently by weather. Subsequently, when removed from the spot of origin, so far from its having been shaped to fit its environment, it at once asserted the contrary by assuming a robust growth, and has finally become a fair-sized specimen, with much-communited tassels at all tips. Another point in this plant is an extra brittleness, also a varietal feature, but by which also, as we have seen, it suffered in its natal environment instead of benefiting. Surely such variation as this, or any sort of variation, indeed, which handicaps a plant instead of aiding it in the struggle for existence, must be "indiscriminate" in the sense of evincing lack of discrimination [sensitiveness]. Again, what advantage is reaped by a plant being rendered utterly barren, a phase of variation not uncommon, and often accompanied in Ferns by considerable enhancement of their beauty? Such plants are found here and there among their fertile companions, and it would be impossible to define any difference of environment, nor is it conceivable how such a variation, which is definite enough in its character, can be in the direction of adaptation to such environment, if the preservation of the species be the object in view.

As regards the relative variability of plants under culture and under natural conditions, the search for and discovery of these abnormal forms of Ferns leads irresistibly to the conclusion that the difference is more apparent than real. That there is much variation in wild plants is shown by the Fern catalogue above cited; and it must be borne in mind that these are generally found as single individuals massed together with all sorts of other plants or species of Ferns in unfrequented places, and that a specially keen eye and great perseverance are needed to find the one "sport" among the tens of thousands of normal forms peopling the same locality. Such finds are often only visible by a projecting tip among a crowd of robust normals, a result of the handicapping already alluded to. Cultivated plants, on the other hand, are under observant and experienced eyes from the spore or seed to the adult stage; and being furthermore classified and isolated, the chances are all against any variation escaping notice. Plants, too, which have once broken normal bounds, are eminently likely to vary again, and it is precisely these that are brought under cultivation and their offspring most carefully watched. Here, however, any selective breeder will confirm that the variation is usually as indiscriminate or indefinite as it well can be, the perfect types being only arrived at by exhaustive weeding-out.

If the environment is a guiding factor, and every variation favoured the individual plant, we should naturally expect to find spreading colonies of varietal forms in localities virgin to the Fern-hunter, but in the immense majority of cases, the fronds are solitary, though the individual plants be often old and well-established, and fully fertile, and thus have had countless opportunities, through their offspring, of their special adaptation to their environments, had such really existed. If we go outside the realm of plant-life and study variation in the animal kingdom, we find the same general divergence often yielding types less fitted to these environments than the normal, so that unless cared for artificially, they sooner or later perish.

Variation in shoots, so far as human comprehension at present extends, appears to be embodied in endless vagaries, upon the underlying causes of which it is useless to dogmatise. It is certain, however, that the hunter for wild Fern varieties will be the last man to accept the theory that indiscriminate (i.e., indefinite) variations have not occurred in wild plants. In making this assertion the writer speaks for himself, since in his experience in Ferny districts, daily finds of definite sports may be confidently counted upon. A return home quite empty-handed forms a rare exception, two or three per outing being the rule; while the quest, be it remembered, is always carried on as far from the haunts of men as possible, so that the factor of culture is utterly eliminated. *Chas. T. Druery, F.L.S., V.M.H.*

KEW NOTES.

GREVILLEA FASCIOLATA.—This is a beautiful greenhouse plant, equal at least in decorative value to the several species of *Grevillea* grown in gardens for their flowers. It has been in flower at Kew for a month or more, and is still attractive with its compact elegant bushy habit, small narrow grey-green leaves, and numerous axillary umbels of bright scarlet and yellow flowers. The Kew plant is 2 feet high, but according to the description in the *Flora Australiensis*, it attains a height of 4 feet, and is erect and bushy. For its possession, Kew is indebted to Mr. J. H. Veitch, who presented seeds of it among a collection brought by him from Australia in 1893. There is a figure of the species in *Bot. Mag.*, t. 6105, prepared from a plant flowered in Mr. Wilson Saunders' collection in 1873. It also appears to have been sent to Kew by D. Baxter, when collecting in Australia in 1829. Of the 150 species of *Grevillea* known, scarcely half-a-dozen rank among first-class greenhouse plants, but among these I would certainly include *G. fasciculata*.

DRYANDRA CALOPHYLLA.

This is a strikingly handsome species of a genus of Australian Proteaceæ which fifty years ago figured prominently in botanical collections, but which are scarcely known in cultivation now. According to John Smith, there were seventeen species of *Dryandra* at Kew in his time, and they were "bushy plants 3 to 5 feet high, some of them stemless, and forming a compact hemisphere of rigid leaves 3 feet high and wide, and thirty-eight years old." *D. calophylla* belongs to this dwarf section of the genus. It is represented in the Temperate-house at Kew by a plant 2 feet across, composed of numerous semi-pinnate, rigid leaves, from 12 to 18 inches long, dark-green above, glaucous-green below; when young they are covered with a rust-coloured tomentum. In the centre of the rosette of leaves is a large short-stalked thistle-like flower-head surrounded by floral leaves, the head proper consisting of a large number of styles and stamens, whitish with a tinge of rose. This plant was raised from seeds presented to Kew by Mr. J. H. Veitch in 1893. A figure of it has been prepared for the *Botanical Magazine*.

FELICIA ECHINATA.

is a shrubby Composite with the habit and foliage of a *Lasiosiphon*, and terminal heads of purple and yellow Aster-like flowers, $1\frac{1}{2}$ inch across. It has lately been introduced to Kew from S. Africa, where it is a native, by means of seeds sent by Mr. W. Armstrong of Port Elizabeth. It promises to be a useful shrub for the greenhouse, the habit of the plant being good, and the flowers, which are developed in spring, showy. The genus *Felicia* consists of about twenty species of South African herbs or shrubs which used to be included in *Asters*. Several species used to be cultivated in greenhouses, in Miller's time for instance, and one *F. (Aster) fruticosus*, is still included in lists of cultivated plants, but I have never seen it alive. A near ally of *Felicia* is the genus *Agathæ*, also South African, and which also used to be included in *Aster*. It is represented in gardens by *A. celestis*, the blue *Marguerite*, cultivated by Miller a century and a half ago, as *Cineraria amelloides*, and for a long time lost until re-introduced through Kew about fifteen years ago.

DIDIERA MIRABILIS.

A healthy young plant of this extraordinary introduction from Madagascar (see p. 110), has lately been added to the Kew collection through the generosity of M. Grandidier. Its successful introduction is highly creditable to the French horticulturists concerned.

ARCTOTIS VIRGATA.

Good seeds of this have lately been received at Kew from South Africa, with the following note:—"It bears large and handsome flowers of that delicate shade of pink typified in the La France Rose, is a free bloomer, has a long flowering season, and grows easily. You will be delighted with it."

CANNAMOB VIRGATA.

has also been received from the same country. "It is about the most striking of all the *Restiacæ*, and I wonder it has not been introduced before. In a bed of a small ravine in the mountains here it forms a dense mass 30 yards wide, and 12 to 15 feet high. Dried specimens give one but a poor idea of the beautiful golden bronzy inflorescence of the male plant. It likes plenty of moisture."

LIBERTIA IXIODES.

This is a pretty spring-flowering Irid related to *Sisyrinchium*, and which deserves to be popular as a greenhouse plant. There is a good example of it among the New Zealand plants in the Temperate-house at Kew, where it is grown in a pan, and has formed an elegant grass-like tuft of bright green leaves each a foot long, from amongst which spring numerous slender erect scapes 18 inches long, each bearing a raceme of from six to nine flowers which are flat and Ixia-like, pure white, and an inch across. Another species also in flower is *L. grandiflora*, which has longer more rigid leaves, tinged with brown at the base, whilst the scapes are shorter, and the white flowers smaller. I lately saw in the Ghent nurseries plants which I was informed are known there as *Magnetia bicolor*, but which are certainly a *Libertia*, probably the variegated form of *formosa* known as *bicolor*. These *Libertias* are pretty, easily grown plants, and they always flower freely in the early months of the year.

Other noteworthy plants now in flower at Kew are *Rosa berberidifolia* and *Lathyrus splendens*, which grow side by side in a sunny greenhouse, their roots revelling in a bed of loamy soil; *Acalypha Sanderi*, a large and beautiful specimen recently obtained from Messrs. Sander & Co.; *Solanum Wendlandi*, now a cloud of big clusters of bright lavender-blue flowers, hanging over the tropical Water-lilies, and having for its companion *Bignonia Tweediana*, whose big yellow flowers are set in a curtain of dark-green foliage; *Epiphyllum Gærtneri*, a beautiful plant, very floriferous and striking in colour, and of much sturdier constitution than the other *Epiphyllums*; *Conandron Ramondioides*, several panfuls with large crinkled bright green leaves, and numerous racemes of elegant pink-tinged flowers. The effort to obtain a cross between this and its near relation *Ramondia* failed, the seedlings being pure *Conandron*; and *Begonia Gloire de Lorraine*, which has been beautiful with flowers since November. *W. W.*

BELGIUM.

REMINISCENCES OF GHENT.

(Concluded from p. 292.)

M. Alf. Van Imeschot's Orchids.—As foreshadowed by the interesting display of Orchids shown by M. Van Imeschot at the Casino, we found the collection at his pretty homestead at Mont St. Amand replete with good things, and containing perhaps the greatest number of species of botanical interest of any amateur Belgian grower. In the first house were some tall specimens of *Elleanthus capitatus*, a rare species of *Sobralia*-like growth, and also some of the showy *Sobralias*; in flower being a number of plants of *Miltonia vexillaria*, *Ada aurantiaca*, the singular scarlet-lipped *Epidendrum pseudepidendrum*, *Brassias*, *Cymbidiums*, &c. In the end of the range were a very pretty batch of *Bertolonias*, and a number of rare species of *Cirrhopetalums*, *Bulbophyllums*, &c.

In the next range the *Odontoglossums* were making a show with good varieties of *O. crispum*, *O. Pescatorei*, *O. triumphans*, *O. luteo-purpureum*, *O. Rossii majus*, *O. Cervantesii*, *O. cirrosum*, &c.; and some few *Masdevallias*, including *M. × Heathi*.

In the hottest house, in which such fine old plants as *Cyrtoceras reflexum* were in bloom, were more rare *Cirrhopetalums* and *Bulbophyllums*, *Vandas*, *Aërides*, and other warm-house plants, some of the *Dendrobiums* being in bloom. At one end was a gigantic specimen of *Grammatophyllum speciosum*, with stems over 8 feet in height. In the *Cattleya*-

house some good forms of *C. Triangæi* were in flower, and other *Cattleyas* and *Lælias* well set with flower-heaths.

In the vinery were a number of showy greenhouse plants, which used to be favourites also in this country many years ago, such as *Eriostemons*, *Fremandras*, *Brachysemas*, *Diosmas*, *Pleroma*, *Thi-pantia*, *Heterotoma lobelioides* covered with showy flowers, and many other interesting things. Outdoors a large garden of trained Pears and other fruit trees are finely cultivated, and promise well for fruit. M. I. Sulle, the gardener, well cares for his interesting charge.

M. Ed. Pynaert Van Geert.—Both the proprietor of this large and trimly-kept nursery at the Porte de Bruxelles and the establishment itself are perhaps better known to British visitors than any other Belgian nursery. Go when you will, there is always an interesting and varied collection of plants to see, and also a fair show of novelties. In the spring-time the

little plants of the white and green *Pandanus Veitchi* a very charming set of new varieties of *Azalea indica*, and some very showy *Anthuriums*.

Louis Van Houtte, père (Soc. Anonyme).—The name of Louis Van Houtte was formerly associated with the most interesting and varied collection of plants, embracing also a fine collection of bulbous plants. But time changes all things, and among others the fashion in plants; and, consequently, this fine nursery, on its new foundation, turned increased attention to decorative plants, and abandoned many others which had probably attracted insufficient buyers to make them profitable. At present there are grown numbers of showy species of Orchids, such as *Odontoglossums*, *Cattleyas*, *Lælias*, *Cœlogynes*, &c., and very well grown the stock appears to be. As a reminder of former times, we found in one of the houses in flower the rare blue *Amaryllis procera*, a number of rich scarlet *Hæmanthus multiflorus* *Kalbreyeri*, and some good *Hippeastrums*. One

of colour, but scarlet predominating; and a fine lot of *Odontoglossums* in remarkably good condition, and flowering well. Among foliage plants, *Dracæna Sanderiana* was well represented, and one house was very effectively displayed with *Anthuriums*, *Cypripediums*, and foliage plants.

De Smet Frères.—At the entrance one is struck by the grand alley of pyramidal Bays, which usually runs from the entrance-gate. On the occasion of our visit their ranks were being somewhat broken, the packers being at work on some of the finest, to send them over the sea. The front of the nursery was bright with *Azalea mollis* and other early flowers, and throughout the seemingly endless ranges of glasshouses the stock was in the most vigorous condition, and neatly kept. *Araucaria excelsa* appears by thousands of all sizes; so numerous are the plants of it that it causes one to wonder what becomes of them all. And yet if you put the question, you always get the same answer, "We never have too many!" Range after range of neat little plants of it appear, one range being filled with cuttings, each under its own bell-glass. Here also the usual species of decorative plants are grown, and house after house of Palms were noted. The houses contained a large number of graceful plants of *Cocos Weddelliana*, which is not now met with in such great numbers as formerly. Stove plants, and especially those with variegated foliage, are extensively cultivated, and a sturdy lot of *Odontoglossums*, and some other Orchids were observed.

Société Horticole Gantoise.—Under the able direction of M. E. Wartel this very extensive and well-kept establishment in the Chaussée de Courtrai has made great headway. Their numerous and fine exhibits at the great quinquennial show doubtless attracted many visitors to the nurseries, and if they were not satisfied with what they saw there they were very difficult to please. Few nurseries can boast of such a large and varied stock of new and rare plants, and in every case the plants are cultivated up to their best. It is therefore a relief after passing through houses filled with a fine stock of the usual decorative plants to come upon some of the warmer houses filled with rarer kinds. Here was a fine stock of a charming new Palm named *Johannia Veitchi*, with graceful, arching foliage, borne on curiously freckled stalks; also a very good batch of pretty plants of *Latania rubra*, long known as an occasional plant, but seldom seen in such condition and quantity as here. Another handsome and still rarer species noticed in quantity was *Phœnicophorium seychellarum*; and *Livistonia rotundifolia*, *Licuala grandis*, *Kentia Lindeni*, *Phœnix Rœbelini*, the singular *Wallichia oblongifolia*, and other rare species, were well represented. *Crotons* and *Dracænas* were in large quantities, and of beautiful colour. Of the *Dracænas*, *D. Warteli*, *D. Sanderiana*, and *D. Godseffiana*, were the most striking of the distinct sections they represent. Among the many showy *Anthuriums* sending up their coloured spathes in great profusion, were several of new and distinct features, and among the *Bromeliads* was a batch of a new *Vriesia* of the *V. splendens* type with green, purple and cream-coloured bars on the foliage, and a very showy scarlet inflorescence. The *Azaleas* were making a most brilliant display; and in the houses devoted to *Kentias*, we noted a quantity growing on for the Paris market with five plants in a pot—a tall one in the centre and small ones around it. These are said to sell well in France.

In the open ground were remarked a large stock of Bays, *Dracæna australis*, and other decorative plants.

SPATHOGLOTTIS × AUREO-VEILLARDI.

OBTAINED by crossing the species specified by its name, this pretty hybrid affords striking evidence of the useful work done by the hybridist in raising new garden Orchids, for it supplies not only a new plant worthy to be grown with the best of the species, but a perfect gem in the elaborate colouring of its neatly-formed flowers, which are not only very attractive at first sight, but well repay careful examination. The plant was first exhibited by the raisers, Messrs. Jas.

FIG. 115.—SPATHOGLOTTIS AUREO-VEILLARDI.

front garden is bright with Tulips and Hyacinths, and this spring the beds were also decorated with the bright and softly-tinted *Azalea mollis* in flower, and the lofty Palm-house and corridor beside the plant houses further contained a brilliant display of them, as well as of the richer-coloured varieties of *Azalea indica*.

In the Orchid-houses there was a good show of *Odontoglossums*, *Cattleyas*, and other showy species, the house devoted to *Cypripediums*, which are a specialty here, having some fine hybrids in bloom, among which we noted *C. × nobilior* (*villosum* × *Haynaldianum*); and a very curious hybrid with shining pallid flowers, obtained by crossing *C. Mastersianum* and *C. Leeatum*. Another singular variety was a hybrid of *C. Chamberlainianum*, and some good *C. exul*, *C. Leeatum*, *C. Rothschildianum*, &c., were in bloom, notwithstanding that the prize collection of *Cypripediums* was on exhibition at the Casino. The decorative Palms, *Araucarias*, &c., grown by the thousand, were in fine condition; and noteworthy among the pretty subjects shown in good batches were the variegated *Sibthorpia europæa*, the tricoloured *Saxifraga Fortunei*, a great quantity of neat

house was filled with showy *Anthuriums*, many with very compact little plants of *Camellias*, and still more with bushy *Azaleas*, a grand lot of them of all shades of colour being in flower. Then follows house after house of *Kentias*, *Latantias*, *Phœnix canariensis*, and other decorative Palms, &c. At this nursery also there is a very extensive culture of plants in the open air. Sheltered by frames are many interesting bulbous plants, terrestrial Orchids, &c., and a grand lot of the *Myosotidium nobile*, otherwise the New Zealand Forget-me-Not.

Louis de Smet.—Here on entering one is struck by the immense quantity of Bay-trees in tubs, and specially pyramid-trained specimens, which, contrary to the usual custom, seem to predominate. Great care must have been taken with the culture of these fine and useful specimens. In the larger houses are huge Palms for decorative purposes, and in the smaller ones thousands of *Kentias* and other Palms; and several houses were filled with fine specimens of *Araucaria excelsa*. Among other plants remarkably well cultivated at this nursery, we noticed a great number of *Anthuriums* with spathes of various shades

Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea, at the Temple Show, 1897, when it was a very small plant; but it succeeded even in that state in securing an Award of Merit.

Messrs. Veitch again exhibited it as a much stronger specimen (see fig. 115) at the Royal Horticultural Society on May 10 this year, when the Orchid Committee unanimously voted it a First-class Certificate. The ground colour of the flowers is of a clear, pale chrome-yellow, the sepals slightly, and the petals profusely, dotted with crimson, and the reverse of each segment shaded with the same colour. The front lobe of the lip, and the tips of the side lobes are also of a rich crimson colour, and the base of the lip is minutely dotted with red.

THE WEEK'S WORK.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Bedding-out Arrangements.—The time has arrived when the work of bedding-out the plants for summer display may begin, provided all the necessary preparations have been made. In that case, nothing need now impede the work where spring bedding is not indulged in. The recent rains will have moistened the soil and brought it into a fit condition for the reception of the plants, and the plants will soon take root. Make sure that no plant is set out that is in a dry condition at the root, or not properly hardened off. To touch upon the innumerable designs of beds and the arrangement of the plants would occupy too much space in these columns, and such matters must be left to the individual fancies and tastes of owners of gardens and their gardeners; still, there is one matter that I may mention, which is, the use of plants in regard to the colours of the flowers or foliage. Make up your mind whether you will have harmonies or contrasts of colour, and do not attempt both in the same bed or even in the same design, or the result will be offensive to persons of taste. Another thing to avoid is, that of having a great mass of colour in one bed without something being planted to tone down its crudity. For small beds, two colours are sufficient, and in big ones three or four are ample. When a ground-work plant is used, care must be taken to have its colour contrast with the other plants employed; as for instance, a bed of Flower of Spring Pelargoniums becomes very effective if some blue *Viola* is used for the ground-work, and the bed is edged with the yellow-flowered *Antirrhinum* Tom Thumb. A large bed may be planted with *Hyacinthus candicans*, and *Lobelia cardinalis*, *Queen Victoria*, or others; a light blue or yellow *Viola* being used for covering the soil, the edging consisting of *Lobelia compacta*, or a dwarf, white-flowered *Antirrhinum*. Let special attention be paid to the heights the various plants reach, and plant accordingly.

Carpet-Bedding.—The designs should be marked out with white sand, and the hardier subjects planted first, the tenderer *Coleus*, *Alternanthera*, &c., being planted in the first and second week in June. Fibrous-rooted *Begonias*, if seed was sown as advised at the beginning of the year, will have become of good size; and as the flowers do not come all of one colour from seed, it is advisable before planting-out to sort out the various colours, and plant these separately. These plants must be gradually hardened off, and a few branches of *Yew*, &c., placed around the edges of the beds for several days after planting. The soil for *Begonias* should receive a good dressing of leaf-mould, and the planting out be delayed as advised for *Coleus*, &c. The beds should be in a sheltered place, as the wind plays havoc with the foliage. This remark applies also to the tuberous-rooted varieties likewise. *Cannas*, *Ricinus*, *Nicotiana*, *Datura*, *Aralia*, *Grevilleas*, *Eucalyptus*, and other sub-tropical plants, should not be planted before the middle of June, when, with the exception of the *Cannas*, a new stake should be placed to each as soon as planted.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Carrots.—Where the seed was sown in drills—and this is the better method for a main crop, let the young plants be thinned out to 3 inches apart, and afterwards afford the land a slight dressing of wood-ashes or charred garden-rubbish in a finely-sifted state. Another large sowing of Scarlet Model, Red Surrey, or the Altrincham Carrot may be made, and also one

of the Short Horn Carrot in smaller quantity. In June the Carentan, and other short-horn or stump-rooted varieties, may again be sown for affording an early winter supply.

Spring-sown Onions.—When Onion seed has matured properly, as ordinarily sown it comes up too thickly, rendering a good deal of thinning necessary; but some portion of the crop should be left unthinned, the operation of thinning being carried out by the daily drawing of plants for kitchen use. The remainder of the crop may be treated in one or two fashions. If big bulbs are required for certain culinary purposes, or for show, they should stand at 8 or 9 inches apart; and if moderate, more useful sizes are the aim of the gardener, the bulbs may be so thinned that when they are ripe they will just stand clear of each other. Some gardeners, knowing the waste that takes place in the kitchen sow the seeds thinly, and let all grow away together unthinned. This method affords bulbs of sizes suitable for a variety of uses, and is, perhaps, the most economical method. When thinning, let all weeds be pulled up carefully, so as not to disturb the Onion-plants; and in dry weather keep the Dutch-hoe in use between the rows. Remove the flower-stalks from autumn-sown and transplanted Onions not intended to produce a crop of seed, and make a small but thick sowing of the Silver-skinned Queen Onion on hard, not over-rich ground.

Seakale.—At this season the flower-stems usually show abundantly, especially on plants of more than a year old, and these must be removed by cutting them off low down, but taking care not to injure the leaves; and to keep the land clean with the hoe. Seedlings should be thinned to 5 inches apart; the thinnings, if carefully drawn, will do for planting elsewhere, or filling vacancies. Dress all Seakale land with agricultural-salt and wood-ashes, not forgetting such of the roots as have been forced in the open under pots.

Winter Brassicas.—Where seeds have been sown thickly it will be prudent to lift and prick out Brussels Sprouts, Broccoli, Couve Tronchuda, Kales and Savoys in variety, before they get attenuated and long-stemmed. A distance of 5 inches apart in the nurse-beds will suit most of the kinds, provided permanent planting is done in June and early in July. A sowing of the Walcheren and Early Penzance, and of late varieties of Broccoli, may now be made. The first two will prove useful late in the year, and the latter will prolong the supply in early summer next year.

General Remarks.—If the sowings of Beetroots, Parsnips, and Onions have partially failed, the plants where they happen to grow thickly may be transplanted to the vacant spots in the rows, planting them not deeper than they were previously. When the spring-sown Spinach is usable, and in sufficient quantity to meet the demand, the autumn-sown Spinach should be turned in, Spinach being an exhausting crop. Clear the land of exhausted crops of all kinds, which, if left, have an untidy appearance, and take much plant-food out of the land.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking

Thunias.—*T. Marshalli*, *T. Bensonæ*, *T. Veitchiana*, *T. alba*, &c., are now in the middle of the growing season, and require abundance of root-moisture. These plants will soon produce their flower-spikes, and as soon as these appear, an alternate application of weak liquid cow-manure will assist them greatly. Until the flowers open, keep the plants on the sunny-side of the house; they should then be removed to a cooler and more shady position. Such *Pleiones* as *P. maculata*, *P. concolor*, *P. lagenaria*, *P. Wallichiana*, are also growing freely at this period, and at such time it is almost impossible to afford them too much water. An occasional dose of liquid-manure will strengthen the leaves, and increase the size of the bulbs. *Pleiones* do well at the cooler end of the Cattleya-house, exposed to considerable direct sunshine, and with plenty of fresh air circulating freely around them. Each afternoon at closing-time let the plants be syringed under the foliage.

The Odontoglossum-house.—At this date *Odontoglossums* form a great attraction, plants of *O. triumphans*, *O. hystriz*, *O. luteo-purpureum*, *O. Hallii*, *O. sceptrum*, *O. Pescatorei*, *O. excellens*, *O. nevadense*, and many other species and varieties being in flower. Whilst the plants are making growth and perfecting their flower-spikes, the usual practice, when damping down in the afternoon is to close the top-ventilators for a few hours; but now that most of the plants are in bloom damping-

down should be discontinued, the flowers being liable to get spotted, more especially in mild and damp weather. The last thing at night, air should be admitted in small amount at the top of the house, which will suffice to let much of the humidity escape. The degree of warmth at night may stand at 54°, and it may fall to 50° or 51° by the morning without ill effects. If the morning is sunny, damp the floors and syringe the stages and between the pots, and as the temperature rises increase the quantity of air. If the weather be dull or rainy, many growers damp only the paths and under the stages lightly. Where many such species are grown some of them will be making growths, and must have close attention. When any plant of the species above mentioned ceases to flower, moisture overhead or at the roots must be cautiously afforded; and all such plants should be kept apart from the others, and induced to rest by keeping their surroundings less moist and the compost moderately drier. Tyros should know that *Odontoglossums* are ruined by carrying their flowers for two or three weeks, and by flowering them too often. Unless plants are wanted for certain purposes their spikes should be cut off after being open on the plants for a reasonable length of time, and used in indoors decorations. Those who possess any of these plants should therefore remember that strong vigorous growth in every plant should be the aim of the grower, and excessive flowering be avoided. These points are applicable also to *Oncidium* *crispum*, *Marshallianum*, *Forbesii*, *curtum*, *concolor*, *varicosum*, and others. Plants of *Odontoglossum grande*, *O. Insleayi* and its variety *leopardinum*, now starting to grow, may be afforded more water at the root, but taking care not to allow any to lodge in the young breaks or these may decay. *O. hastilabium*, which is a plant that is now in growth, should be placed in the cooler part of the Cattleya-house in order to afford the flowering-breaks strength.

HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Gooseberries.—Owing to the extremely drouthy weather that prevailed in most parts of the country during March and April, the Gooseberry-bushes will probably be suffering from attacks of red-spider; and those that are weak suffer first, or most severely, from spider, and the pest eventually spreads from such to younger bushes, and is then with difficulty eradicated when once fairly established in a plantation. An attack weakens the bushes very much after a time, reducing the size of the fruit considerably. Red-spider is usually most abundant on the under-surface of the leaves, and is difficult to dislodge unless a syringe with an elbowed rose-jet be used to conduct the stream of water to that side of the leaves. Owing to the tender skin of the fruits at this date, it is not prudent to apply strong insecticides, and a sud made with the best soft-soap at the rate of 4 oz. to the gallon of rain-water is the safest. This should be applied with a syringe during dull weather to the under-side of the leaves and branches, and it has most effect if it be allowed to remain on the leaves and shoots; a second syringing taking place after an interval of four or five days. When Gooseberries are required for cooking purposes, the bushes must be well syringed with clear water the morning following the dressing, and the fruits be also washed before cooking them. Old bushes, if badly-attacked by red-spider, should be grubbed-up after the fruit is gathered, that is, if they can be spared. Strong healthy bushes may be greatly assisted to recover from an attack by applications of liquid-manure to the soil at intervals of a fortnight, and by gathering all the fruit in a green state. The Gooseberry benefits by high feeding when it is carrying a heavy crop of fruits, and it is a practice with many of the Kentish growers to form a basin around each stem when the fruit is about half grown, and to place night-soil therein, turning the dug-out earth over it; and by this means very heavy crops are obtained. After much of the green fruit is gathered from a bush, the foliage will have got firmer, and better able to withstand a solution 50 per cent. stronger than is prudent to give it at an earlier stage. Bushes much infected are sure to be in a worse state the following year unless preventive measures are persevered in, the insects hibernating beneath the bark.

Pears.—This fruit-tree forms a favourite feeding-ground for numerous insects and the larvae of moths, &c. The leaves are disfigured and injured by a minute acarid, *Phytoptus Piri*; then plant-lice, *Aphis*, attack the leaves, viz., *A. Piri*, *A. Mali*, which cause honeydew. These last are best destroyed by Tobacco-water, or Quassia-water at

this season, and by white-washing with lime in the winter has a good effect. Scale insects affect the trees, and the best means is the last named, only using skim-milk instead of water, and some clay to give it body. In the folded-up leaves live the larvæ of *Chimatobia brumata*, a little winter moth; and several Tortrix, and *Ornix petiotella*. On the expanded leaves there are *Ornix guttata*, and the gall-fly, *Cecidomyia Piri*. These are the commoner forms of insect-life on our Pear-trees, and they must be sought for and destroyed by the various means known to gardeners. The garden-engine, used with or without insecticides, is capable of doing much to keep a Pear-tree in health, especially if means be taken to feed the plants by manurial dressings, and to maintain health by affording water at the root if there is a suspicion that the soil lacks moisture.

Weeds.—The rains have caused weeds to grow fast, and advantage should be taken of a dry state of the ground to pass the Dutch-hoe over all vacant spaces and between the rows of plants, bushes and stools. Dandelion, Dock, Couch-grass, Thistles, Bindweed, and Plantain, should be dug out entire with hand-forks. These are noxious weeds in fruit plantations, and the most difficult to eradicate in such places, although persistent cutting off the tops as fast as they show will destroy them eventually.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Euphorbia pulcherrima (Poinsettia).—Cuttings made from soft shoots, or from eyes, may, when well rooted be shifted into 60's, employing a compost for them of fibrous loam and peat, and leaf-mould in about equal proportions, and adding to these sharp sand sufficient in quantity to make the soil properly porous. The potting should be done firmly, and the plants put close to the glass. For two or three weeks after repotting let them remain in the stove, and afterwards afford intermediate-house treatment. Good heads of flower bracts may be obtained from plants confined to a single stem, and grown in 6-inch pots; but if large specimens are required, two or three year old plants should be cut back to within about two buds of the two-year-old wood, then be started in stove heat, and when these buds break, the plants should be shaken out of the exhausted soil, and repotted in new compost. Aphis and thrips often infest the plant, but these pests may be got rid of or greatly reduced in numbers by fumigation with XL All, and Tobacco, aided by gently syringing the leaves twice a day with rain-water, and maintaining a genial growing atmosphere in the pit or house in which the plants are growing.

Pentas carnea and P. rosea, useful winter-flowering plants, with flowers of delicate pink tints, which are produced abundantly, may now be increased by means of cuttings struck in a hot-bed frame or the propagating-house. The rooted cuttings should be grown on in light loam, leaf-mould, and sand, and receive warm-house treatment till the plants bloom, when the intermediate will be the proper place for them. These plants remain in good condition in apartments that are not too cool, and are therefore very suitable for indoor work.

Cyperus.—The species *C. alternifolius*, the variegated form of it; *C. laxus*, *C. l. variegatus*, and *C. distans* are valuable plants for decoration, either under glass, in pots, or planted in borders or as portable subjects in the dwelling. All of them thrive in a compost consisting of peat, light loam, leaf-mould, and sand. The drainage should be good, as they require much water when actually growing.

Gardenias.—Plants raised from cuttings rooted in August or September of last year, and now growing freely in 6-inch pots, may have the points pinched out if the growth is sparse, and be kept growing in the stove. Those plants which having ceased to produce flowers plentifully, were cut back some weeks ago, will have made sufficient growth to furnish cuttings for propagation purposes, which may be undertaken in any hot-bed having bottom-heat of 80°, or in the propagating-house, and even in a vinery if there is a bed of leaves therein. The present affords a suitable season for clearing the plants of mealy-bug and scale. Any old plants that are kept after the cuttings are taken may be started in brisk heat, if with bottom-heat all the better, being syringed every day twice or thrice, and keeping them close till free growth ensues.

Coleus.—The plants raised from early cuttings will in turn yield a supply of shoots fit for cuttings, which may be trimmed and inserted in pots or pans of light sandy soil, and placed on gentle heat. The stock

plants should be carefully afforded water till growth recommences, and then be repotted and afforded liberal treatment in a light, warm-house.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Strawberries.—At the beginning of March the growth of out-door Strawberry-plants was very forward, but since then the nights have been so cold that the fruits will be late. The weather must be very favourable if Royal Sovereign, on a south border here, is to be ripe by the middle of June. To prolong the supply of fruits from plants in-doors until such date, another batch of pot-plants will need to be put into the Strawberry-house. If the plants when taken in-doors are in bloom, the blooms may be thinned down to eight or twelve of the largest to each plant, according to the size of the fruit of the variety, the larger the fewer. Strawberry-plants when in flower require abundance of fresh air to obtain free-setting and well-shaped fruits. When the temperature keeps up to 60° in dull weather and 70° with sun-heat, too much air cannot be given them. The hot-water pipes need only be heated slightly on cold nights and in dull weather by day. Strawberry plants standing on dry shelves in houses require water once on most days, and twice if the sun be bright. Afford weak manure-water to plants now swelling fruits. Frequent doses are best, and the manure should contain phosphates, ammonia, potash, and lime. Plants on which the fruit is colouring do not require such frequent application of water. Syringe thoroughly plants with swelling unripe fruits once or twice a day in bright weather. Any plants left after the batch now taken inside is removed should have the blooms thinned in the same proportion as those taken in. They may be taken afterwards inside to finish, or they may be retarded by being placed on the north side of a wall to yield fruit when the crop from the outside beds is waning.

Peaches.—When the fruits commence to ripen place a net under each tree, at such a distance below the fruits, that, as they fall into it, they will not be bruised. Any on extreme parts of the tree that the net would not catch may have a piece of old net fixed loosely round each. The fixing of the net should not be deferred too long, as fruit falling on the floor is spoiled. Peaches, like other stone fruit, are of the highest quality when ripened on the trees, and in the case of fruits for home use, this is always practicable. For packing Peaches, the ordinary Covent Garden box is very suitable, being light, and three or four of them make, when tied together, a convenient package. The size of the box is 18 by 12 inches, and 3½ inches deep, inside measurement. Each fruit should be wrapped in a square piece of thin, soft paper, so that the packing material does not touch it. The softest wood-wool and finest-wadding are suitable packing materials, placing a layer at the bottom and on the top, with sufficient pushed in between the fruits as will prevent movement. In packing, it is well to err on the side of closeness, although it must be done with as little and as delicate handling as possible. Peach-trees bearing fruits colouring or swelling have required during the dull, damp weather we have recently had, a little heat in the hotwater-pipes during the day, with ventilation. Avoid too-frequent syringings in such weather, but make up for it by doing the work thoroughly whenever it is fine. During the swelling-stage, Peaches require much water at the roots; and only close observance and experience will tell the gardener just when the trees need it, and if it be more frequent than usual, this is a good sign, for the roots are then in a healthy condition, have good drainage, and open soil.

THE APIARY.

By EXPERT.

Combs.—If anyone has any combs with candied honey in them, or granules of candied honey not thoroughly cleaned out last autumn, I advise that the combs be sprayed with lukewarm water and given to the bees to clear out before new honey is stored in them; any granules left in the comb will start granulation of the new honey very quickly, and may spoil the sale of the sections later on in the season. Newly-hived swarms should have a little help for a few days when first established. A pint of syrup given three or four nights will prove a paying investment, even where full sheets of foundation is given, but more especially so when the swarm is hived on starters only. It is the treatment of the hive in autumn that, to a large extent, determines its success the following year. Hives that are kept at work till

the month of September on the heather, frequently return depopulated. Such require an addition to their numbers, either of driven bees or joining several lots together. Nearly everyone has found that driven bees formed into stocks in autumn, when put on built-out extracted combs fed up quickly to the required weight, are the ones as a rule that come out strongest and swarm first the following year.

Strengthening.—All that can be done, must be done in nursing any stock weak in bees, but which are making rapid progress. Keep the slow-feeder constantly going if food be scarce, or uncap sealed stores once or twice a week if there is plenty on hand. Suitable spring food may be prepared by pouring three pints of hot water on 5 lb. of white cane-sugar, stirring till the sugar is dissolved, and giving the food lukewarm. Keep the entrances narrowed till the bees become busy, and they require room for going and coming. See that the quilts fit closely down, and that no heat escapes at the top of the hive. When the first overhaul of hives is made, let it be really thorough, and make a note of their condition, this note to be tacked inside the roof, or secured where it will be easy to refer to when needed. On this state what progress is being made in brood-rearing, and what feeding, &c., is required, and do not disturb the brood-nest again so long as progress is maintained until the weather becomes warm and settled.

Giving more Space.—Save in early districts, it will be time enough to think of giving surplus chambers when our next number is issued. Some stocks which have wintered on a few frames will require additional combs early in the month. No disturbance of the brood, however, is needed in affording these. When there are bees on all the combs, add a frame on each side once a week till the full complement is inserted. Should the weather be favourable, and a colony is strong, I usually add the full number of combs at one operation, to save further trouble.

Swarming.—When, May is warm and sunny, care is needed in checking the issue of undesirable swarms from strong stocks. With plenty of surplus space, however, added after the bees have got well at work in the limited space first given, they may be kept so busily occupied in comb-building as to stave off the swarming impulse which usually arises when the pent-up energies of strong colonies, hitherto held in check by adverse weather, are suddenly aroused amid warmth, sunshine, and the abundance of natural food.

Nothing should be left undone which will be useful later. Hives, supers, syrup for feeding, &c., must be prepared ready for use. Parcels of things which have been stowed away during the winter should be examined and put in order, so that they may be at hand when wanted; in fact, now is the time to look over everything which is likely to be required both for swarming and supering, in order that make-shift appliances need not be used—and, above all, the necessity avoided for doing work in a hurry, which means doing it badly.

Total Honey Imports for 1897.—The total value of honey imported into the United Kingdom during the past year is shown in the following monthly returns for 1897, as furnished to the *British Bee Journal* by the Statistical Office, H.M.'s Customs:—January, £267; February, £1666; March, £1310; April, £1293; May, £1706; June, £1921; July, £5791; August, £1987; September, £1852; October, £2123; November, £656; December, £1489. Total for the year, £21,861.

FRUIT REGISTER.

PEAR TRIOMPHE DE VIENNE.

I WAS pleased to see your able correspondent, "G. B.," speak well of this valuable Pear. So far, I have not grown it on walls, but as a standard tree, for several years it cropped very regularly. It is an excellent Pear to follow Williams' Bon Chrétien. By going over the trees at intervals of a few days, and taking off the forwardest of the fruits, the season may be greatly prolonged.

PEAR BEURRÉ D'AMANLIS.

This early September Pear has been in commerce for years, and it is well known to many. The fruits from a healthy, well-cared-for tree are of a very large size, but I have repeatedly found that medium-sized fruits with a little colour are the better flavoured. The flesh is melting, very juicy, and slightly perfumed. The tree is a good cropper. *H. Markham, Margate.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY,	MAY 21	Royal Botanic Society, General Meeting.
TUESDAY,	MAY 24	Linnean Society (Anniversary).
WEDNESDAY,	MAY 25	Royal Horticultural Society's Show in the Temple Gardens (3 days). Bath and West and Southern Counties Society's Exhibition at Cardiff (5 days).
FRIDAY,	MAY 27	Royal Botanic Society, Lecture.

SALES.

MONDAY,	MAY 23	Japanese Lilies, Hardy Perennials, Carnations, Palms, &c., at Protheroe & Morris' Rooms.
TUESDAY,	MAY 24	Imported and Established Orchids, at Protheroe & Morris' Rooms.
FRIDAY,	MAY 27	Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—56° 6'.

ACTUAL TEMPERATURES:—

LONDON.—May 18 (6 P.M.): Max., 57°; Min., 42°.

PROVINCES.—May 18 (6 P.M.): Max., 57°, Achil Head; Min., 48°, Aberdeen.

THE *Revue Scientifique* recently published a note to the effect that "there is a class of soluble ferments, such as diastase, pepsine, and ptyaline, which for some time past has attracted the attention of chemists and bacteriologists. It is known that analogous ferments exist also in plants, and SACHS ascribes to them an important place in the phenomena of nutrition, growth, &c. These ferments are numerous or abundant in bulbs, buds, tubers, seeds, &c. At the end of autumn the plant has generally formed and accumulated considerable alimentary reserves, in the shape of starch for instance, and their existence can be proved. These reserves are stored up until the spring, when they are utilised for the important work of vegetation, which takes place at that season almost before the roots have recommenced activity, and the leaves are not yet developed to collaborate in the common task. The utilisation of these reserves can, there is no doubt, only take place with the assistance of ferments which aid in digesting and rendering assimilable the nutritive materials. The case of a bulb is typical. A bulb which receives no other food than distilled water, whence it can draw no nutritive matter—puts out leaves, roots, and flowers;

and it is owing to the accumulated reserves which constitute the greater part of its substance, that this development is made. The case of a seed is not less obvious. Certainly it is not food-material obtained from distilled water that suffices during the first phases of the development of the young plant to form the radicle, stem, or cotyledons. These are the store-house of nutritive matters, at whose expense the growth is made. Is it not in seeds when germinating that the brewer seeks diastase—malt?

Mr. WAUGH's experiments bore witness to the vitality of seeds. It is known that many seeds obtain their maximum germinating power only after a certain time. With some maturity is very rapid, with others it is slow.

On the other hand, the power of germination, after attaining a maximum, diminishes and ceases. After two, three, ten, twenty years, according to the species, the greater part of the seeds lose the faculty of germinating, although, according to circumstances, this loss is very variable. (See the experiments of BROWN and ESCOMBE, of VICTOR JODIN, DE CANDOLLE, &c.) To what is this deterioration of the germinating faculty due? Is it to a loss or diminution of "vital principle?"

Mr. WAUGH believes that this phenomenon can be most reasonably explained by supposing it to be due to a diminution in quantity or deterioration in quality of the indispensable ferments contained in the seeds. He therefore made certain experiments on the action exercised by solutions containing ferments on the germinating power of old seeds which had partly lost their germinating faculty.

In the first case he submitted some old seeds of Tomato, twelve years old, to the action of different solutions containing ferments, and the following is the result obtained:—

Test: Control (seeds in pure water) germination	23 per cent.
Seeds in trypsin, germination	56 "
" " extract of pancreas, germination	36 "
" " enzymol, germination	52 "

In a second experiment, also with seeds of Tomato twelve years old, he found:—

In pure water, germination	34 per cent.
In diastased water, germination	70 "

A third experiment gave the following results:—

In pure water, germination	12 per cent.
In pepsine	80 "
In diastase	85 "

On the whole, in this latter case the germinating power was increased from 5.67 to 6.08 per cent. by the use of ferments. With other soluble ferments, and other seed, Mr. WAUGH obtained corroborative results. These experiments have an obvious practical interest, on which there is no need to insist; they have also a great scientific interest, in that they show the importance of ferments, and indicate that the hypothesis formed by Mr. WAUGH shows decided probability. It would be well for these experiments to be repeated and increased to ascertain which is the ferment most useful according to circumstances, and according to the species of the seeds.

VIEW IN MR. ARDERNE'S GARDEN (Supplementary Illustration).—The characteristic charm of the semi-tropical vegetation, arboreal and other, of this interesting example of a garden at the Cape, induces us, as it has on previous occasions, to present our readers with another view from the same garden. This view depicts a less well-trimmed and dressed part of the grounds, where the vegetation is of a more indigenous character, and where running water

lends its peculiar charms to the landscape. We may take it that the stream is never dry, even in that somewhat thirsty land; hence the bridge, and the luxuriance of the vegetation in the hollow, through which the stream flows. The summer-house in form is likewise indigenous, and, as far as the roof is concerned, a reproduction of a Kaffir-hut, and it is, moreover, spacious, and suggestive of cool-air currents, even on the hottest day.

MR. GLADSTONE GONE!—The decease of this venerable statesman on Thursday morning last is a national event, that has aroused the sympathies of the English-speaking race throughout the world. Born in December, 1809, the whole of his long life and remarkable powers were devoted to work, and the greater part of this was performed in the service of his country. We are of no party in politics, but the close of such a life of persistent effort to obtain for the country what personal conviction had declared was necessary and right, oftentimes in the face of enormous opposition, is a moment when all differences are stilled—when the noble character and work of the departed are alone remembered. Mr. GLADSTONE always felt an interest in *petite cultures*, and doubtless his advice to cottagers and small farmers to grow small fruits for sale in the towns, and to makers of jam, has been abundantly followed, with good pecuniary results to the growers. He had an interest in woodcraft generally, and was as expert in planting as in felling trees. The chief lessons Mr. GLADSTONE'S life offers to us as gardeners are persistence in duty and a determination to master as far as possible, the smallest details in the science or art in which we are engaged.

"BOTANICAL MAGAZINE."—A fire which occurred at the lithographers has prevented the issue of plates 7593 to 7596 this month. In consequence of this accident, the only plant of which a figure is given in the May number is:—

Amonium hemisphoricum, which was received from Mr. RIDLEY, Director of the Botanic Garden of the Straits Settlements. It is a Scitamineous plant of tufted habit, with long erect branches, bearing shortly-stalked, oblong acuminate leaves of a reddish colour beneath, and about 18 inches (46 cent.) long. The flowers are borne on separate stalks, shorter than the leaf-stems, and gathered into globose heads surrounded by crimson, green-edged, boat-shaped bracts. Flowered at Kew.

ROSE EXHIBITION AT GOTHÄ.—A great exhibition of Roses is arranged to take place at Gothä in connection with the Industrial Exhibition, and will last from July 10 to 12. Every information will be afforded by the local committee at Gothä and the officials of the *Verein Deutscher Rosen Freunde*, from whom schedules can be obtained.

THE THREATENED DISFIGUREMENT OF RICHMOND HILL.—It appears that a scheme is afoot to construct a light railway, worked electrically on the overhead trolley system, along the Queen's Road, in front of Richmond Park gates, and descend the beautifully wooded slope of Petersham Hill. In this case, unfortunately, the appeal is not to Parliament, as in the case of the Westminster Thames Embankment; but all that is necessary is for the London United Tramways Company, the promoters of the scheme, to obtain an order from the Light Railway Commission, and the approval of the Board of Trade. It would be a great pity if the Light Railway Act, which was mainly intended to facilitate the transport of agricultural produce in sparsely inhabited rural districts, should be made use of to inflict irreparable damage on the picturesque beauty of the district of Richmond and Petersham. Surely means can be taken to keep the Philistine despoilers at a distance from this, one of the few beautiful spots left untouched round London.

PRESENTATION TO MR. W. HOWARD.—A large number of Kingston friends of Mr. HOWARD, who was for thirty years attached to the Coombe-wood Nursery of Messrs. JAS. VEITCH & SONS, and for a long portion of that time as manager, took occasion

FIG. 116.—THE POND IN MR. ARDERNE'S GARDEN CLAREMONT, CAPE TOWN. (SEE P. 312.)

on the evening of the 11th inst. to present him with a handsome acknowledgment of his long connection with the town. Mr. HOWARD has recently left Coombe-wood to occupy a similar position with Mr. ANTHONY WATERER, at Knaphill. The presentation, which took the form of a handsome, gold, keyless, lever, hunting-watch, and a purse containing £10 10s., was made by Mr. A. W. HOMERSHAM, J.P., ex-mayor.

OPEN SPACE FOR SHOREDITCH.—On Saturday afternoon, Charles Square, Hoxton, acquired by the London County Council and the Shoreditch Vestry at a total cost of £1000, was formally opened to the public, the ceremony being performed by Mr. G. SHAW LEFEVRE, one of the representatives of the borough of Shoreditch in the London County Council. The square had hitherto been open only to the inhabitants in the four blocks of houses by which it is surrounded. It lies in the midst of a very thickly-populated area, which had practically no recreation-ground.

"ONE-AND-ALL" NATIONAL FLOWER SHOW, 1898.—This great annual show of amateur horticulture will take place on August 19 and 20 at the Crystal Palace, concurrently with the National Co-operative Festival. The prizes amount to over £350 in cash, besides gold, silver, and bronze medals, framed certificates, and other awards. The Agricultural and Horticultural Association contribute over £200 to the prize-list, and the Crystal Palace Company £150. The schedule includes seventy-two pages, and the introduction states that last year 34,695 visitors attended the show, which comprised over 4000 exhibits, extending nearly a mile in length. The Hon. Secretary's address is 3, Agar Street, Charing Cross, W.C.

IMPROVING EXETER PLEASURE GROUNDS.—The work of remodelling the Northernhay Pleasure Grounds at Exeter, which was entrusted by the city council to the firm of Messrs. ROBERT VEITCH & SON, was completed last week. One of the alterations had been rendered necessary by the lack of space around the band-stand, which was quite insufficient to accommodate the number of persons who wished to listen to the music. This is only one of the improvements carried out, but it is such a common one, owing to short-sightedness when laying out many parks, that it may be well to emphasise the importance of proper selection of site, and the securing of a sufficiently large plateau around a band-stand in the first instance. Other desirable improvements have been effected, and considerable planting done, which has added much-needed variety amongst the hardy shrubs.

THE DOVER FLOWER-SHOW will be held in the Dover College Grounds on August 17 and 18. The schedule includes 120 classes, the first section, embracing fifty-nine, being open to all England. A score of classes are reserved for allotment-holders in the borough who cultivate not more than 40 perches of land.

BATH AND WEST AND SOUTHERN COUNTIES SOCIETY.—This old established society will hold its annual exhibition from May 25 to 30, in the Cathays Park, Cardiff, where the local circumstances are such as should help to make the event a great success. The various sections of this wide-embracing show include live stock, working dairies, implements and machinery, fine arts, art manufactures, horticulture, horse-shoeing, milking, music, &c. The entries for the forthcoming exhibition exceed in almost all cases those made in 1882, when the society last visited Cardiff.

GOLDIE'S CANADIAN DIARY.—In a pamphlet published by WM. TYRRELL & Co., Toronto, we have the *Diary of a Journey through Upper Canada and some of the New England States*, taken in 1819 by Mr. JOHN GOLDIE. This traveller, born in Ayrshire in 1793, went to America first in 1817, at the instance of Sir (then Mr.) WILLIAM HOOKER. After a second visit in 1819, the notes of which are now before us,

he again returned to Canada with his family and remained there until his death, at the age of ninety-three, in 1886. The diary before us is not a scientific one, Mr. GOLDIE'S botanical journal having been lost by fire, but it is not less interesting for that, especially for non-technical readers, who will enjoy his accounts of a country which, no doubt, is in many ways changed in the past eighty years. A pleasing item in the pamphlet is an illustration of *Aspidium Goldieanum*, discovered by this traveller, and named after him by Sir WILLIAM HOOKER. Mr. GOLDIE'S original description of the Fern is also given.

AN ORCHID SALE.—The sale of some of Mr. THOMPSON'S Orchids on the 11th and 12th inst., at Walton Grange, Stone, by Messrs. PROTHEROE & MORRIS, Cheapside, London (writes a correspondent), was well attended by Orchid-growers and experts. The plants generally were in capital condition, and there was a good show of *Cattleyas*, *Dendrobiums*, *Laelias*, and *Odontoglossums*, in the houses. The arrangements for the sale, which were in the hands of Mr. STEVENS, the skilful gardener at this place, were very satisfactory. Below are some of the highest prices realised for single plants, the fine *Odontoglossums*, of course, fetching the largest sums:—*Odontoglossum crispum* Golden Queen, with 1 bulb and 1 strong growth, 160 gs.; *O. septrum aureum*, with 4 bulbs, 140 gs.; *O. nebulosum album*, with 3 bulbs and 1 growth, 15 gs.; *O. elegans*, Pollett's var., with 1 bulb and 1 lead, 7 gs.; *O. Coradinei expansum*, with three bulbs and 1 spike, 20 gs.; *O. excellans*, 3 bulbs and 1 lead, 20 gs.; *O. crispum* Kate, with 3 bulbs and 3 growths, 20 gs.; *O. aureum*, with 1 bulb and 1 growth, 26 gs.; *O. Wilckeanum* var., with 1 bulb and 1 lead, 15 gs.; *O. crispum* Stevensi, with 6 bulbs, 2 leads, and 1 spike, 110 gs.; *O. c. Alfred*, with 3 bulbs and 2 leads, 24 gs.; *O. Ruckerianum ocellatum*, with 1 bulb and 1 lead, 50 gs.; *O. Wilckeanum nobilior*, 33 gs.; *Cattleya labiata* Peetersii superba, with 3 bulbs and 1 lead, fetched 75 gs.; *C. Victoria Regina*, with 4 bulbs, 44 gs.; *C. Skinneri alba*, with 15 bulbs and 4 leads, bearing 4 sheaths, 30 gs.; *Laelia anceps Dawsoni*, with 5 bulbs, 6 gs.; *L. Gouldiana*, with 8 bulbs, 11 gs.; *Laelio-Cattleya Pallas*, with 3 bulbs and 1 lead, 12 gs.; *Epiphronitis Veitchi*, with 11 growths, 7 gs.; *Oncidium ornithorhynchum album*, with 3 bulbs and 2 growths, 10 gs.; *Cattleya labiata cœrulea*, with 2 bulbs and 1 lead, 28 gs.; *Cypripedium insigne* Dorothy, 1 old and 2 new growths, 21 gs.; *C. Rothschildianum giganteum*, 1 old and 1 new growth, 20 gs.; *C. Charles Richman*, 10 gs.; *C. insigne* Dorothy, 1 old and 2 new growths, 21 gs., in two instances.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY: NEILL PRIZE.—At a meeting of Council held in Edinburgh on the 18th inst., Mr. THOMAS LUNT, gardener, Ardgowan, was awarded the NEILL Prize for the biennial period to May 15.

MESSRS. MACKENZIE & MONCUR'S ESTABLISHMENT.—The fire on the night of the 12th inst., which resulted in the total destruction of the premises of these well-known horticultural builders in Edinburgh, caused damage to the extent of £20,000. The discovery of the fire was made shortly after six P.M., after the employees, other than the office staff, had left for the day. Notwithstanding all the efforts of the fire brigades, whose work was extremely difficult, owing to an insufficient supply of water, the fire was not brought under control until it had quite destroyed the works. Of the contents destroyed, there were several valuable wood and iron-turning machines, tools, and a large quantity of stock in glass, iron, wood, &c. There was also in course of construction within the works a large winter-garden for Stanley Park, Liverpool, and an addition to the temperate-house of the Royal Gardens, Kew. We believe the loss is quite covered by insurance, and the firm have already made arrangements for rebuilding the works, and temporary premises have been found. A similar fire occurred at the works some years ago.

BOOK NOTICE.

FLOWER FAVOURITES; their Legends, Symbolism, and Significance. By Lizzie Deas (London: George Allen, 156, Charing Cross Road).

THIS is, as regards binding, print, paper, and general get-up, as pretty a little book as could be desired. On testing the contents, we find the stories of some fifty familiar flowers, both garden and wild favourites, told in simple and pleasing language. Some of the chapters have, we are told, appeared on former occasions as magazine articles.

The legends and quotations cited may not be new to every one, but are certainly much less hackneyed than might have been expected in a book of this kind, and we are thankful to be spared certain but too-often repeated sayings and quotations which other writers upon flowers seem unable to repress. The extracts cited are well and neatly put together, not put in one after another until a chapter is supplied. Nor has the writer gone to the opposite extreme of filling up vacant spaces with long and wordy paragraphs of her own composition.

There are similar books to the one before us, avowedly, and of necessity, compilations rather than original matter; but, as may be inferred, the present is a favourable specimen of the class. It shows varied reading and research, and presents us only with gems of thought, not with anything unpleasing or jarring. As an indication of the kind of narrative quoted by the authoress, we select the following legend of the Carnation, taken from E. Gerard's *The Voice of a Flower*, and telling how the armorial bearings of the house of Ronsecco come to be charged with a *Garofano*, or Carnation:—

"Many hundred years ago, at the time of the Crusades, a daughter of this house, Margherita Ronsecco, loved a brave and chivalrous knight, who bore the name of Orlando. Their marriage was already fixed, when a call resounded through the country, summoning all good knights and gentlemen to repair to the Holy Land, and seek to deliver the Saviour's tomb from the power of the infidel. This was a summons to which none but a dastard could turn a deaf ear, and Orlando, though torn by grief at having to leave his adored Margherita, and see the cup of bliss thus dashed from his lips at the eleventh hour, yet never dreamed of hanging back. 'Farewell, *anima mea*,' he murmured, clasping her to his heart. 'Be true to me, beloved,' she sobbed; 'do not forget thy Margherita in yon distant land.' 'Never while I breathe! But give me this flower that nestles on thy sweet bosom, to wear as a talisman next my heart.' Blinded by scorching tears, she fastened the white Carnation to his mailed breast-plate, then one more last embrace and he was gone—gone never to return.

A year later Margherita was waited upon by a strange horseman, who brought her mournful tidings from the Holy Land. Orlando had fallen in battle against the Saracens, and from his dead body had been taken a withered white flower, which, together with a lock of Margherita's fair hair, had been found on the warrior's breast. The Paynim arrow, which with deadly aim had found its way to the true knight's true heart, had likewise pierced through the silken bag containing this talisman, and his warm life-blood, welling up from the death-wound, had partially dyed the once snow-white blossom to a deep crimson hue. This precious relic, now the only thing remaining to her of her beloved, was treasured up by Margherita with tender reverence, and seeing that the flower contained some tiny seed-vessels, there came to her the thought to plant these in a pot of earth. Carefully, anxiously, she watched the flower-pot day by day, bedewing the earth as much with her abundant tears as with water from the fountain.

At last—oh joy and consolation! some tiny green sprouts began to appear, which soon developed into a strong and vigorous Carnation, covered with tightly rolled up buds. But oh, wonder of wonders! when these began to unfold, they proved to be quite different from the flowers of the original plant from which they had sprung, for while in each bloom the outer rim was snowy-white, its centre was marked by a deep crimson stain, like the blood which had stained Orlando's withered blossom. And it was this miracle, wrought by the Almighty in order to show the power attached to true and faithful love, that caused the head of the Ronsecco family to have a red and white Carnation emblazoned on his coat of arms. Margherita never married; with loving fidelity she tended her precious flower, and when, after a very few years, she pined away and died, she left the Carnation as a legacy to her sisters, with the injunction never to bestow one of its blooms on anyone, save the man to whom they had plighted their troth. Thus the plant became a sort of heirloom in the Ronsecco family; the cuttings of the flowers were only multiplied in each generation according to the number of maidens, every daughter of the house receiving at her birth a vase containing a plant of the white and crimson Carnation. And so it came to be asserted that whenever a maiden of the Ronsecco house was destined to die unmarried,

as surely would the plant wither away and perish; and if a daughter of the Ronsecoos lost her honour, or had given away her flower to an unworthy lover, then the flower would be blighted overnight."

If the name Marguerite Carnation is familiar to our readers, this ingenious way of accounting for the origin of it is surely less well known.

The writer of this little book does not confine herself to English literature, but gleans from Greek and Norse mythology downwards, and includes references to various continental traditions.

The Germans are famous for the pretty legends which have gathered round the names of their plants, and the following one, which is supposed to account for the Cowslip being called St. Peter's herb, tells the little story in attractive language: "St. Peter heard it whispered in Heaven that people were contriving to gain admittance by means of a back entrance, in place of by the front doorway, of which he is the keeper; and such was his agitation at the suggestion, that he let drop his bunch of keys, which, falling down upon the earth, there springs from them the beautiful little yellow flowers commonly known as Himmelschlüsselchen, or Keys of Heaven."

We will not quote further, or we shall anticipate the pleasure future readers will take in the book. It is a volume for reference and occasional use rather than for steady perusal, and for all flower-lovers, for those who have adopted some pet blossom, or who bear a "flower" name. These will be interested in the accounts of the Daisy, Edelweiss, Pansy, Iris, Lily, Rose, and Violet.

It further occurs to us that it was wise, when putting this book together, to limit the number of flowers of which it treats and also to include some comparatively-neglected specimens, such as wild Chicory, Basil, Leek, Marjoram, and Sainfoin. In fact, there is every reason to congratulate the authoress on her work, which will prove a very storehouse of quotations to future compilers and magazine writers.

GUNNERSBURY HOUSE GARDENS.

IN Messrs. de Rothschild's gardens attached to Gunnersbury House, increased facilities have been acquired during the past season or two for the forcing of fruit trees. Several span-roofed houses, 66 feet long by 18 to 24 feet wide, have been built, resembling in some respects those in the famous fruit-tree nurseries of Messrs. Rivers & Son at Sawbridgeworth. They run from east to west, and in the important matters of ventilation and light they are admirable. They are small matters that go to secure success in fruit growing—the following for instance. In most fruit and plant houses the bottom ventilators in the wall are hinged from the top. These at Gunnersbury are hinged at the base, and when opened therefore admit air from the top. Many gardeners will at once see a reversal of practice in such a system, but it provides for the admission of fresh air, without the degree of cutting draught that may take place when the shutters are opened the reverse way. The new houses are really orchard-houses, that is, they provide for the forcing of standard trees in pots, without the trellises or trained trees common in most fruit houses. When visiting the gardens a fortnight ago the Nectarine fruits in the earliest house were ready for the table. The variety was Cardinal, a new one sent out by Messrs. Rivers, and capable of being forced in a much shorter period than any previously existing sort. This is another instance in which the Sawbridgeworth firm has conferred a boon upon fruit growers and consumers. Mr. Hudson has every reason to be satisfied with the measure of success he has already achieved in forcing these pot fruit-trees. The Cardinal Nectarines, for instance, which have now ripened, give from ten to fifteen fruits per tree, and as these are of good size, and apparently of high quality, it is a very good return. It would be a great advantage were there a few early Peaches of equal quality and habit, but at present they are not to be had. Early Beatrice Peach in the same house was a little behind the Nectarines, but has since ripened. Jefferson's and Reine Claude du Comte

Atthems Plums in the same division bore good crops of fruit. Mr. Hudson declares he is agreeably surprised to find that Plums may be forced so readily. Early Transparent Gage and Kirke's varieties are equally satisfactory. In another house was a collection of late Nectarines and mid-season Peaches of the choicest kinds, and in a third house a collection of Apple, Pear, and Cherry trees. Apples, and particularly Cox's Orange Pippin, promised exceedingly well, and Pears and Cherries are satisfactory. The earliest black Cherry, which was ripe at the end of April, is Guigne Annonay, and Bigarreau de Schrecken is also a very desirable variety. In a smaller house Plum and Peach trees have just set their blossoms. In a lean-to house a fine tree of Lord Napier Nectarine has a crop of over 400 fruits. The tree was planted by Mr. Hudson twenty years ago, and now fills the house, which is 24 feet long by 13 feet wide. It was started on the 10th of December last, and Mr. Hudson expects the fruits to ripen about the end of the present month. In four years the tree has ripened 1,800 fruits, and may be regarded as a very productive specimen indeed. The border was well made in the first instance, over a solid concrete bottom.

Two divisions of a span-roofed house were filled with Royal Sovereign Strawberry plants, in one case with ripe fruits, and in the other with fruits approaching that stage. This is truly a grand Strawberry for forcing, and we have nowhere seen it better done than at Gunnersbury. The plants were on a step-stage and from either side faced the path in the centre. As the houses run east to west, the plants would get a fair amount of sunshine, but were further removed from the glass than Strawberries are usually placed. Royal Sovereign throws its flower-spikes up boldly from the plant, and they usually require to be staked, as the fruits were here. The plants seldom fail to fruit freely, and the fruits are large, of good colour, and capital flavour. Mr. Hudson also forces a quantity of Vicomtesse Héricart du Thury Strawberry plants, but these are not forced because the variety is better than Royal Sovereign; but if they be forced early and planted out soon afterwards, this variety will fruit moderately well again in the autumn. Some of these had already been planted out in the border for this purpose; about a thousand alpine Strawberries also are fruited each year at Gunnersbury House.

In the Fig-house the trees had just yielded their second crop of fruits. They were started on October 17 last, and the first fruits were ripe on February 16. Of the varieties forced here, the best are St. John and Pingo de Mel. It is a pity that gardeners are so little interested in Fig culture, that in many instances they go on year after year forcing old varieties like Brown Turkey and Negro Largo. These are excellent Figs for summer or late crops, but for hard forcing the two already mentioned are much surer to carry a crop of fruits. More than this, although Brown Turkey is a large fat fruit, generally appreciated, it is not so good in flavour, or so thin in the skins as some others. By all means grow Brown Turkey, but at the same time give the newer ones a chance, as in the case of other fruits.

In the earliest vinery, containing pot-Vines, Grapes were ripe on April 30. The varieties include Royal Muscadine, Black Hamburgh, and Foster's Seedling. There are twenty-eight Vines, and the bunches of fruit in the house averaged five to each Vine—a very satisfactory crop.

In the plant-houses the specimen plants of scented-leaved Pelargoniums were being overhauled, and the first training for the season commenced. These plants have been exhibited at Shrewsbury, as well as at London shows, consequently their character is very well known. Mr. Hudson has got together a good collection of varieties—all, in fact, that have come under his notice.

Though Orchids are not so numerous here as in many gardens, there are added from time to time various useful species. There is a fine lot of Vanda coerulea, one of the most charming Orchids, and Mr. Hudson looks forward to obtaining several dozen spikes of bloom this season. We noticed a large piece of Lælia purpurata with ten flower-spikes.

The original piece was purchased by Mr. Hudson's father in 1862, at Mr. Stevens' sale rooms, and the plant we noticed is from a piece taken from the plant in 1870. There has been no "degeneration" here, at least. There is a good batch of plants, also, of Dendrobium formosum giganteum.

We next proceed to the lake, where the Water-Lilies have just been planted. Mr. Hudson has a fine collection of Marliac's hardy Nymphæas, and we hope to see them when in bloom. A small pond is to be made in the garden also where the water will be heated, and blue Nymphæas cultivated.

The faces of the Rhododendron beds, and, indeed, wherever space was available, have been planted with Liliums, which are expected to make a fine display in late summer.

A visit to the very novel Mushroom-house, where excellent crops are obtained from the cellars belonging to the original Gunnersbury House, and we had completed an inspection of this most interesting and well-kept garden. P.

FAN-TRAINED MORELLO CHERRY TREES.

THE management of the Morello Cherry, when planted against a wall, is very similar to that pursued with the Peach in this country. The tree should be pruned early in the spring, whilst the buds are still dormant, reserving plenty of last year's shoots at full-length, but not crowding them. Some gardeners allow these to grow at right angles to the face of the wall, instead of laying them in against it, with astonishing results in the matter of crop. The shoots which have borne fruit, if not required for filling vacant spaces, or extending the area covered by the tree, are removed at the winter pruning, and new are laid in. Summer disbudding of superfluous shoots, and selecting next year's fruiting ones, must be sedulously carried out, and all main shoots nailed in securely, in such a manner as to secure an evenly-balanced fan-shaped tree. Our illustration (fig. 117) shows such a tree growing at Stoneleigh Abbey, Kenilworth, Lord Leigh's beautiful Warwickshire residence. Mr. Martin, his lordship's gardener, who sends the photograph from which the picture was taken, states that it is one of a number of Morello Cherry trees that occupy the northern side of a wall 9 feet high and 150 feet long, which fruit splendidly most years. The trees are young and vigorous, and consequently they produce great crops of very fine fruits.

A north wall affords a capital means of retarding the fruits and keeping them when ripe till late in the autumn; but Morellos and similar varieties of Cherries, as, for example, Belle Magnifique, make very prolific bearing and neat standards, in which form it is an easy matter to protect the fruit from the depredations of blackbirds and thrushes with fish-netting.

FOREIGN CORRESPONDENCE.

THE FISH RIVER.

SUNDAY, January 2.—I took one of our Hottentot labourers, loaded him with provisions for three days, a botanising-tin and paper, and started for the Fish River, where, as it is the only stream of our colony, that in good years runs for two to four months, I supposed a quite different and wonderful vegetation would be found. The plain, which I traversed on a very little used footpath, is interrupted by chains of small sandstone hills, and offers very little to the botanist. The whole plateau, whether sandstone, sand, or clay, is covered with enormous green bushes of the broom-like Euphorbia, now bearing on the top of its branches two or five locular fruits (not 3-locular, as those of all European species), with the same number of seeds. They are of the size of a Lathyrus seed, and very oily. On the base of this spurge is now flowering a very curious fleshy red parasite. It is a three-lobed flower of 5 to 6 inches diameter, in its construction much like the flower of the S. European Cytinus. The Hottentots call it Chanib, and eat it, although it contains (like Cytinus) so much tannic acid that it at once colours a knife

black. *Parkinsonia africana* (Lamoonboom of the Africans) is now flowering with thin bunches of flowers. This is a rather ugly, tall shrub, not to be compared in elegance with *P. aculeata*; the seeds are used by the natives in times of scarcity as a substitute for Coffee. The Stinkbush—I take it for a *Celastrina*—is a very robust, almost globular shrub, with clusters of small green flowers, having a most unpleasant fecal odour. It can be smelt for a good distance. *A. capparidea* is a tree 15 to 20 feet high, and a stem 1 foot thick, with greenish, insignificant flowers, and bean-like fruits (contracted between the seeds). The finest plant is *Rhigozum trichotomum*, a verticillately-branched shrub, covered two weeks after the first rain with Azalea-like, sweet-smelling white flowers; it is a Bignoniad, like *Catophractes Alexandri*, which is very common, too; both are most worthy of introduction into the Riviera gardens. On the same high plateau are common three red-flowering *Hermannia*, and a wonderful *Asclepiad* of the tribe *Stapelie*, resembling a *Cereus*; it has about fifty columns or stems 1 to 2½ feet long, each bearing on its top a ball of six to ten magnificent reddish-brown flowers 2 to 3 inches across. This is doubtless the finest succulent plant of the whole country, and could be

sour. The botanist does not find here what he might expect from the united action of water and heat; the species are the same as he finds in any dry river, only more luxuriant, namely, *Acacia horrida*, *Euclea pseud-ebenum*, *Tamarix austro-africana*, a shrubby Composite, with small violet heads, and a few more common things.

Three hours' further walk over another plain, on which *Euphorbia* abounds, brought me to the Fish River, the only river of importance in this country. It is a periodical water-course, here about 75 yards broad, and 2 feet deep in its deepest place, of clay-yellow colour. The scenery along the river banks is very picturesque. There are on both sides perpendicular rocks, very similar to the famous sandstone rocks of the "Saxon-Bohemian Switzerland." The shining, bright green of the *Ziziphus*, the sweet-scented golden-yellow trusses of *Acacia horrida*, make the landscape very lovely. I did not stop long here, but climbed the black rocks on the left bank, and slept in the sandy bed of a tributary stream. The silence of the night was interrupted for hours by the fearful noise of a herd of baboons. The next afternoon we arrived again at the banks of the Fish River, just opposite the newly-built house of one of our

a *Marsilia*, a pretty white-flowering *Veronica* (?), and, growing on the Tamarisks, a *Loranthus*, with beautiful red flowers and red berries. As I had time, health, and food, I decided to extend my excursion as far as our capital, Keetmanshoop.

KEETMANSHOOP.

About the trip to Keetmanshoop I have very little to say. After three hours' walk from Sechim, Mr. W.'s place, I arrived at the foot of the Shangkop, a perfectly conical peak in the wide shrub-covered plain, only 300 feet high, but visible from a long distance. Next forenoon I arrived in Gobas, on the left side of the Schaaprivier, where, in one of the three existing pits, I got, by digging with the hands, some black and disagreeably smelling water. I could use it only for coffee-making; it was, at least, not salt. On the stems of the fine *Acacia horrida*, which are scattered over the river-sands, I noticed large exudations of the best white gum, which my Hottentot preferred even to my meat and biscuits. I tried it also, and found the wet flowing gum especially of an excellent sweetish taste. Hottentots often live for weeks exclusively on this gum, and it is also the chief food of the baboons. The path, a real and rather

FIG. 117.—MORELLO CHERRY-TREE IN FLOWER AT STONELEIGH ABBEY, KENILWORTH. (SEE P. 314.)

very easily exported by thousands to Europe if there were a better communication with the coast. The transport-riders cannot fill their waggons with goods when going down, as they are obliged to load them with grass for the desert which separates the coast from the interior, otherwise their cattle would die of hunger by the road. Hottentots are fond of the *Stapelie* and allied plants, although they are as bitter as *Quassia*.

I descended from the high plateau into a very deep and stony valley, whose slopes were covered with *Cereus*-like spiny *Euphorbia*, 8 feet high, the stems of which are crowned partly by rather large green flowers, partly by fruits of the size of a Cherry. There is also growing a stemless *Aloe*, unknown to me, with red flowers and remarkably small fruits. It is quite a wonder to me how this plant can grow there between the stones, which are so hot that they burnt even through my very thick boots. At the mouth of the above-mentioned valley I found a flat green spot, with a small fountain between the Thorn trees (*Acacia horrida*), Tamarisks, and Ebony trees (*Euclea*). Here, in the shade of the latter, we reposed for several hours, and enjoyed the rare view of the green carpet of sour grasses around us. It is very peculiar, that in this country the best grass for cattle, the *Poa-grass* (*Aristida*) grows on stony and very dry places only, and in dry sands, whilst the grass (*Scirpus*) in the neighbourhood of fountains is always

oldest hunters and farmers, Mr. W. I was received by him and his family with that cordiality which is only to be found among Africans. Whether they are Dutch, English, Scotch, German, or French, it makes no difference. Mr. W. has started here, on the sandy banks of the Fish River, a plantation still in its commencement, but very promising. Virginian Tobacco and *Nicotiana rustica* looked very fine, and were partly ready for harvesting. Beans, Batatas, Pumpkins, and other vegetables, were as fine as in any European garden. The actual garden is not large—about 2 hectares, but it could be extended to at least 8 hectares, and about 10 hectares might be planted with timber-trees. I advised the proprietor to plant *Eucalyptus*, especially such species as *E. globulus*, *marginata*, *amygdalina*, *Casuarinas*; and some of the West Australian *Acacias*, such as *A. dealbata*, *decurrens*, and *Melanoxylon*. I saw a seed-bed with several hundreds of *Acacia pycnantha* ready to be planted out in a few weeks. Mr. W. has more water than he wants; and in winter-time, when the Fish River does not run, there remains in its bed, just in front of his garden, a natural reservoir, 6 to 9 feet deep, and 1000 yards long, which can never be emptied. Mr. W. has the advantage, that his ground is not salt, or only so slightly that it is harmless to the plants.

Of botanical curiosities, I found in this place only

good waggon-road, ascends from Gobas slowly to Keetmanshoop, where I arrived late at night. I remained there from the sixth to the twelfth of January.

The *Bezirkshauptmann* (Provost), Dr. Golinelli, received me with much kindness. He is a great friend of gardening, and has the most earnest desire to render Great Namaland important services in that direction, but there are not yet means for so doing. He showed me in his garden wonderful healthy seedlings of *Pinus halepensis* and *Eucalyptus globulus*, which he intends to plant out between the magnificent Camelthorn-trees (*Acacia giraffæ*) which lend an unsurpassed charm to the young settlement. The front of Dr. Golinelli's house, which is standing amidst the garden, is adorned with four slender specimens of *Aloe dichotoma*. One day I rode with my host to Warmbakis, a farm on the Lion River. The vegetation on the way to that place was beginning only now to awake from the long hibernation (the first rain having fallen two weeks ago in the district of Keetmanshoop), whilst in Inachal the *Rhigozum*, *Catophractes* and other shrubs had already flowered in the first half of October, ten days after the first rain in that district. As the time from one rain to the next in this country is generally sufficiently long to make everything flower and ripen its seeds, a second heavy rain permits the vegetation to flower and ripen seeds for a second time in the same season, and I was told

by old settlers that many plants sometimes ripen the seeds for a third time.

I found on the way to Warmbakis an Acacia called Chanu by the natives, a shrub only 7 to 10 feet high, with many stems, most agreeably-scented flowers, and long thorns like those of *Acacia horrida*. I never saw it before. An interesting *Euphorbia* of the Caput Medusæ section, occurring in great quantities, was also new to me.

The Lion river, which we reached after four hours' riding, offered nothing new, only Acacias, Zisiphus, Euclea, and Tamarisks. Thus I came to the conclusion that the borders of periodical and perennial rivers in this colony offer to the naturalist much less than do the dry plains and hills. The borders of the rivers, especially of the Fish River, are better for gardening and timber-growing, as it is stated that vegetables grow best in Namaland, in the saltless sandy deposits of the rivers if manure is used, and there is also in the dry winter time a copious water supply. K. Dinter.

(To be continued.)

HOME CORRESPONDENCE.

FROM AN IRISH GARDEN.—I have now coming into flower in the open air a fine spike of a Yucca-like succulent sent to me as *Beschorneria glauca* many years ago, which has proved quite hardy here so far as frost is concerned, but during one of our long wet and almost sunless winters the rain lodged in the centre and rotted the heart out of the plant; but soon five or six strong offshoots sprung up all round the central corpse, one of which is now blooming. Its stem is as bright a red as Rhubarb, and all up it are deep rose-coloured sheaths or bracts, each of which encloses a bunch of green buds. I can find no such variety as *B. glauca* mentioned in the books, though the foliage has a distinctly glaucous hue, so it may be *B. yuccaoides*, or the *B. bracteata* of *Bot. Mag.* It is certainly not *Furcraea Bedinghausii*. I have a new *Deutzia* named *D. macrosepala* coming into flower for the first time received from Lemoine. Two of the fine set of new Japanese single and semi-double tree *Pæonies* sent out by Croux, of Chateau, for the first time this spring, are now in bloom with me, and are most beautiful. The best of these, Madame G. Croux, figured in the February number of the *Revue Horticole*, will also bloom here later on. It resembles a huge florist flower Tulip. W. E. Gumbleton.

PEACH AND APRICOT-TREE PROTECTION.—The fact that moisture and cold together are inimical to the flowers of these trees must have induced a worthy old gardener in charge of a large place in the north for many years, and who has now joined the majority, to cover the 6 feet-broad border, in which his Peach, Fig, and Apricot-trees grew, with light strawy stable-litter. This was put on after the pruning and tying of the trees were finished. He must have known that the lightly-lying litter stored the sun's heat, and gave it out during the night, much of it ascending the face of the wall. Moreover, the border was forked over after the work on the trees was done, so that moisture passed quickly away, not lying on the surface as would be the case on ground that was much trampled. As a further protection to the bloom, branches of Spruce, or Balm of Gilead Firs, were secured flat against the wall, and sparingly, just touching each other. These were put on in early spring, and remained in place till the middle of May, by which time the needles had entirely dropped from them, effecting, in fact, a very safe, thorough, and withal, gradual uncovering. The "set" was usually a good one when the preceding summer had been warm enough to ripen the wood, which was not always the case in that northern clime. Does the pungent, and to us agreeable, fragrance of the Fir deter aphides from breeding on the young shoots and leaves of stone-fruits? If this should be the case, country gardeners have a remedy ready to their hands, for we never found the tiresome insects on trees protected in the manner I have described, although the tender foliage seemed to be more than usually inviting to aphides after the Fir-branches were removed. We have Fir-tree oil as an insecticide, why not Fir-tree boughs as a deterrent? F. M. F.

—Were it limited to that, the majority of Peach-growers would probably go in for a short course of protection. The trees hardly need it till they are in flower. Nature, in fact, renders the closed buds of Peaches and Nectarines frost-proof, with scales and coverings admirably adapted for the purpose. To

protect closed Peach blossoms is to cover twice, that is, to coddle them, or make the bloom abnormally, unnaturally tender. And this state and condition of things is far worse and more dangerous than non-covering. But surely a safer means may be found between the two extremes, that of excessive covering resulting in an augmented tenderness, which more than neutralises any possible benefit to the heavy risk of exposing wide open naked Peach flowers to 10° or 15° of frost. Peach blossoms were not made in Britain, nor fitted unaided and alone to win the victory nor land their fruit crops in safety in a life-and-death struggle with our most capricious and erratic climate. All culture may be defined as but another name for protection, training, assistance, and there is no reason why we should not adopt means of keeping off withering winds and blighting frosts from our Peach blossoms and embryo fruits, as we do green or black-fly from the leaves and shootlets. It should be the mission of the cultivator to protect his trees and blossoms by every means in his power from all that would endanger their crops, or shorten or enfeeble their lives. Most growers agree that the shorter the period of protection, and the less of it, if sufficient, the better; but this is an altogether different matter from being assured that the protection of the blossoms of Peaches in the open air is evil, and only evil, and that continually. This is far too large and general a statement to be accepted either on any foundation of logic or of safety. Modes of culture in most gardens are largely moulded by environment. And this is emphatically so in the matter of protection. It is less a matter of abstract principle than of expediency. Mr. Carmichael says, "I never covered my wall-trees at Sandringham." True; but did he not protect them with warm brick walls, and did not the sea spare some of its latent heat to play across the face of his trees in winter and early spring? I too have seen many cases of success in Peach culture without the practice of the ordinary means of protection. But was there, therefore, no protection of walls or woods, hills or dales, rocks or mountains, rivers or seas, are these and other equally or more potent shelters or protections to be welcomed, and the flimsy covering of a few nets, Fern fronds, sprays of shrubs, over the naked blossoms of our wall trees wholly rejected or condemned. While most cheerfully accepting all my friend's facts, and having special pleasure in stating that we have seldom or never had a better Peach-grower outside or under glass than Mr. W. Carmichael, formerly of Sandringham, whose Peach-walls were the admiration of the country; still, I would caution young growers against wholly discarding protection for their Peach-trees. At Sandringham, Arundel, and Bath, Mr. Carmichael was specially favoured by his surroundings. He was also an adept in training trees, and in thoroughly maturing the wood of his Peaches and other fruits. But neither ripe wood nor strong flowers help Peach-trees on the open wall to protect their embryo fruits on a clear night, with insatiable radiation from earth to sky going on, and the thermometer pointing to 15° of frost. Spread net, scrim, canvas, or a screen of boughs between the trees and the open sky, the loss of heat from the trees is instantly checked, and the crop saved. This is equally true as the fact that, in certain localities, and under special culture, crops of Peaches may be gathered annually without the aid of the usual methods of protection. The question resolves itself into this: Are there special methods of protecting Peach, Nectarine, Apricot, Plum, Pear blossoms on walls, and other trees in the open air, worth the candle? My answer is emphatic: thereare. And the grower who can, may grow and train his Peaches into model forms, and ripen wood and buds into nut-brown colour, solidity. The dormancy of the buds may safely be left to decide as to the time, the measure, and extent of the protection needed to save his crops without weakening his trees or fostering the growth of insects. D. T. F.

ACROPHYLLUM VENOSUM.—It is very seldom now that one sees a fine specimen of this lovely plant. When it was first introduced, I obtained a young plant of it. I grew it in Exeter peat, with a liberal sprinkling of sand and broken flints. The Exeter peat is in large sods, which should be used in the following manner:—Place them on the potting-bench, and with a strong stick break them first, then put it through an inch sieve; pick out all the Heath roots, but retain all the Fern roots. What the sieve retains is placed over the drainage, then a good sprinkling of broken flints is given, which keeps the drainage open. At the first exhibition of plants at Cheltenham, I showed a collection of twelve stove and greenhouse

plants, and was awarded the 1st prize. Many London exhibitors were there. The *Acrophyllum*, grown in a 15-inch pot, was one of my telling plants. I was offered £15 for it. Another very telling plant in my collection was *Chorizema Henchmanni*, a plant one now seldom sees. It was grown in the same compost as the *Acrophyllum*, also the *Boronia*. I was pleased in looking into the Botanic Gardens to find that Professor Balfour has made a start to grow Cape Heaths, but he tells me that he cannot purchase them now for money. I had the great privilege of being under the late W. McNab, who was the father of Heath growing, so I was pleased to find that the Professor has made a start with them, as he is very fond of them. With a view of again bringing such lovely plants into cultivation, I will be pleased to send you an article on their cultivation. When I left Crowl Hall, Bath, I had a house of over 100 of the choice hardwooded kinds. Mr. Tugwell was a great admirer of them. He had an excellent knowledge of hardwooded plants. William Carmichael, 14, Pitt St., Edinburgh.

WHITE BROCCOLI.—What a remarkable experience we are now having of the mildness of the past winter in the wonderful profusion of white Broccolis seen on every hand! I had thought that they must have come from the North of England chiefly, and possibly they do so; but I saw a whole waggon-load in Kingston a day or two since, showing that they had just been cut locally. We have thought that having white Broccolis in good form in the month of May showed exceptional lateness in the variety. It is now May 14, and there have just been brought into my house from a shop a couple of heads of singular firmness, whiteness, and perfection of form. These were not specially selected, but were representative of the bulk; the largest has a head of the most solid, marrowy matter possible, is so conical that the centre stands up 4 inches above the base, and the head measures 12 inches across and 7 inches in diameter. If wanted for exhibition, nothing could be more perfect, yet it is but one of thousands cut from a field. Well may we pause when what were nearly three weeks earlier presented for notice as new, and specially inferior in appearance, before regarding them as either new or late, in face of the fact that splendid heads are to be had in myriads in the markets so much later. The variety I have before me may be Late Queen, or Model, or Methven's June, or something else; but I defy anyone to furnish under any name a more perfect sample at the middle of May. But then, how rare is it that we have this wealth of white Broccoli at this time of the year! How seldom, when winters are of their ordinary severity, do we escape great injury to our white Broccolis! All lovers of good vegetables have just now much to be thankful for, and specially so have the market growers, because a merciful winter has enabled their white Broccolis to come to perfection. A. D.

A HEN'S FREAK.—The other day, at the seat of Chas. J. Massey, Esq., Closes Hall, Bolton-by-Bowland, a gardener who was cleaning a bed in which grows a large specimen of English Yew, discovered a hen's nest in the Yew some 12 feet from the ground, and the nest was found to contain a quantity of eggs. It is carefully made with all sorts of material, carried there by the hen. She goes to the nest regularly to lay, and no doubt expects to bring a brood from it. Although thus imitating the blackbird, she cannot forget her habits, and she cackles each time before leaving the nest, which circumstance betrays her. W. A. C.

A VARIEGATED-LEAVED DENDROBIUM NOBILE.—With reference to Mr. Ringham's note in your issue for May 14 (p. 299), I may say we have also a small sport, the variegation in which is very similar to that of *Dracæna Lindenii*. Mr. Ringham says that he bought the plant which produced his variegated form of the Liverpool Horticultural Company five years ago, and the plant was said to be from a new district. The parent-plant, from which I removed my small piece, is a very large one, in a 12-inch pot, and has been in this garden for a much longer period than five years; and it is just the ordinary type of *Dendrobium nobile*. J. Farquharson, The Gardens, West Denton, Scotswood-on-Tyne.

JUDGING AT SHOWS.—In your issue of May 14, in a paragraph dealing with the judging at the Ghent show, you call attention to the quick way in which the awards were recorded. This is nothing new, as Mr. Barron used to do the same thing many years ago in connection with the shows held at South

Kensington. "The Field" judging-book was used. This is simple in the extreme, and there is not the slightest chance of any mistake occurring, as the counterfoil kept by the judge was marked in the same way as the slip that was torn off and sent to the secretary's office in order that the clerk might enter the award against the name of the prize-winner. As fast as every class was judged it was recorded in the entry book. I have been at many shows during my life, but have never seen the judging and recording of the awards so well managed, and at the same time so correctly as at South Kensington by Mr. Barron. *An old Hand.*

MUSHROOM-GROWING EXTRAORDINARY.—I have cultivated Mushrooms in a wooden shed without artificial aid, and so numerous were they, that with the help of a boy it has taken me over three hours to gather those that were ready for use. I sold them for 1s. per pound. Four days before the photographs I send you were taken, every saleable Mushroom had been gathered. *G. Holmes, Acomb, York.* [The photographs kindly sent by our correspondent showed an enormous crop of Mushrooms of all sizes. Another photograph sent represented some very fine Broccoli cut from the open ground on February 9 last. *Ed.*]

LAWNS.—The rains which the agriculturists so much enjoy, and through the agency of which fine hay-crops are looked for, are giving a good deal of trouble to gardeners, because their lawns need mowing twice a week rather than once; that means a large amount of extra work, and no labour furnished to meet it. There is but one way in which a difficulty of this kind can be fully met, and that is in the furnishing of machines for mowing lawns that will work with much greater rapidity than the present ones do. Some day, perhaps, mechanical skill may produce mowers of such enhanced speed and usefulness, that the gardeners of that day will regard as ancient fossils the machines we now use. We must look for such improvement in the application of superior motive forces to those now furnished by animal or human power. Steam applied to the lawn-mower is a great advance; but why not electricity in the form of accumulators capable of fixing to mowers of all sizes? How heartily such application of a mysterious motive force would be hailed by gardeners. *D.*

SOME SWEET PEAS OF RECENT INTRODUCTION.—I do not think that the dwarf white Sweet Pea, Cupid, has proved a success. In my own garden at least, where I have given it a fair trial in various situations, it has proved a veritable failure; the plants growing indifferently, and the flowers being invariably destroyed so soon as expanded by rainfall. My near neighbour, Mrs. McDonall, at Logan House, tells me, that though she planted it in great quantities in her extensive gardens, her experience has been precisely the same. Its nature, manifestly, is entirely unsuited to our somewhat too humid Scottish climate, which is only congenial to moisture-loving flowers. I anticipate that the new "Pink Cupid," which hails from California, will prove much hardier and more reliable than the white form of similar name, especially as there is no family connection existing between these, the latest novelty having been derived from Blanche Terry, one of the finest of the tall-growing Sweet Peas, and which has always been greatly admired, by reason of the Apple-blossom-like colour of its flowers. I should think that, for bedding purposes (for it only grows about 6 inches high), the Pink Cupid is likely to prove, unlike its white predecessor, a considerable acquisition. This season I am growing the Egyptian or "Mummy" Pea, which produces large clusters of flowers of a rosy-white hue at the end of long fragile stems, in a line with the latest of Eckford varieties; and I am certain that this arrangement will be, during the flowering season, very highly effective. The Egyptian Pea, which, I understand, came to this country in a mummy from Egypt, [No.] I possess through the kindness of Mr. Wm. Davis of Drummone, in this parish (an enthusiastic amateur horticulturist), who obtained it last year from his friend Mr. Day, the accomplished head-gardener at Galloway House. Mr. Davis describes it as unique in habit, and highly artistic in effect. It is at present growing with the strength of the strongest culinary Peas, and with great rapidity. *David R. Williamson.* [A fasciated variety merely. *Ed.*]

MICROBES IN WATER.—After reading your leader of the 7th, re the effect of fungoid microbes on cuttings, and their abundance in the air and in water, I could but wish it were in my power to experiment with boiled water in watering plants in the early seedling stage. So susceptible to damping as

are indoor-raised Cauliflowers and Stocks, so far as my experience goes, few plants raised from seed are more susceptible to this damping than these are when just about to form rough leaves. Amateur gardeners are constantly in trouble from this cause, and as often asking for advice. I wish some gardener who has to raise these plants under glass without heat—for there is less trouble when warmth can be given—would next spring test the merits of unboiled and boiled water, to see whether any difference resulted. But with respect to cuttings, damping, or being destroyed by fungus, we all know that this trouble is greatly minimised when the cuttings are of firm wood, and are not of a soft, sappy nature, and also the soil in which placed is composed chiefly of sharp porous sand. The sand facilitates root-action, no doubt; but if what is stated in your leader be exact, it is now better understood that in creating porosity, the water, laden or otherwise, with fungoid-microbes, the more quickly passes away, comparatively harmless, to the cutting; whilst, if the soil be stiff and close, the water is held about the cutting, and damping caused by the fungoid germs, soon ensues. Bell-glasses may protect cuttings from contact with the atmospheric microbes, but damping is common in such cases all the same; and it is not improbable that water is the chief agent in producing that damping, as it brings the microbes directly into contact with the cut base of the cutting, which is in such case necessarily its weakest part. *A. D.*

ARTIFICIAL MANURE.—Having read in your issue of the 7th inst. the article on "The Use of Artificial Manures," I should like to state my experience, with a view to a better understanding of what seems to be a problem. I may say that all my past experience is fully in accord with the paper by J. J. Willis. I have used artificial manure on farm-land, in the nursery, and in the greenhouse and stove, and always to the immense advantage of judicious mixture of animal and artificial. Some fifteen to twenty years ago a small meadow (that had been let to a small farmer, who had done it badly) came into my possession in March, and was shut up for grass. The crop that year was so poor that a neighbouring farmer remarked when the grass was cut, that he could see a mouse run across it. The next season it was manured as follows:—About ten tons of horse-manure was carted on to the meadow, then sulphate of ammonia, superphosphate of lime, gypsum, and salt were added, the whole being well mixed up, and then spread on the land. The whole dressing was arranged to cost £3 per acre, not including labour. The result was an immense crop, that the grass had to be carted on other land to make it—it was the talk of the neighbourhood. We have always since used artificial manures in mixtures, and find it answers well. Nitrate of soda, or sulphate of ammonia, if applied by itself, and a very heavy storm follows, gets washed into the ditches. For meadowland we mix the manures in a shed, and let the heap lay untouched for a week; and we always have a good crop of hay. The mixture is changed every year, with a view of getting a crop of Mushrooms as well as hay. In the nursery we have found that it is dangerous to leave men to use artificial manures, and have a manured in which I keep it. I have lost large numbers of trees and shrubs, for when a man finds that a dressing—say of sulphate of ammonia—does good, he then doubles it, and kills the trees. So now for many years I make a mixture of which animal manures form the basis and bulk; and this is necessary, for where you have rows of trees and bulbs close together, animal manure could not be dug in even if you could get it in sufficient quantity; this is where artificial manure in mixture is so valuable, and, what in my experience, is of great advantage, it is not so soon gone, it is less soluble, and more suitable to plants when in connection with humus or animal-manure. For pot-plants in the greenhouse or stove I use as a basis about 75 per cent. of either human or cow-manure, the latter generally because of the objectionable smell of the former; we then add sulphate of ammonia, superphosphate of lime, and sulphate of lime (gypsum), in either case the mixture must be in a new wet state to dissolve the ammonia or soda; it is then allowed to dry, and thoroughly sifted several times. This mixture is found suitable for delicate Ferns, Palms, and wonderful for winter-blooming Pelargoniums. I always use gypsum to make the mixture last, and I have had this, kept dry, for years and have not found any depreciation whatever. The above is much the same as the most successful of the artificial-manure mixtures so extensively advertised. So all my experience points to artificial manure being very

valuable in mixture, and of very little value by themselves. If the German experiments are true, it seems to point to artificial manure as being useless, because if of any good to the land it must contain a quantity of manure (humus), and the denitrifying bacteria at work destroying or freeing the nitric acid, the scientific experiments seem very puzzling and contradictory; and while I read Mr. Willis' paper with pleasure as confirming my experience, the recent papers have been quite alarming, and I shall want strong contradictory evidence to shake my faith in mixtures. *J. P.*

MARKET GARDENING.

TOMATOS AND CUCUMBERS.

VINERIES and peacheries in which Tomato plants are planted in rows in the borders right and left of the central pathway must be treated expressly for the Tomatos in the matter of temperature, the object being to obtain as heavy crops of Tomatos as possible from these houses during the first two or three years following construction. The Vines and Peaches will, meanwhile, make short-jointed, sturdy growth, similar to that to be encouraged in the Tomatos, until they have set one or two clusters of fruit each. After this a warmer and moister atmosphere may be afforded them, without fear of causing an over-luxuriant growth. Until the fruiting period, a night temperature of 50° to 55° will be ample, and the ventilators should be opened a little when the thermometer registers 60° in the daytime. Keep the soil uniformly moist about the roots of the plants, the atmosphere being kept rather dry than moist until the flowers have set. A 2-inch deep top-dressing of short dung should be laid on the borders.

The plants should be afforded support when about 9 inches or a foot high. Soft string may be fastened somewhat loosely round the stem of each plant, fairly close to the ground, and then secured perpendicularly to the wires of trellis provided for training Vines and Peaches to; but should this provision not yet have been made, $\frac{3}{4}$ -inch tin-tacks driven into the side of the rafters immediately above the rows of plants, to which the top ends of the strings may be secured, will answer admirably. All side-shoots should be pinched out close back to the main stems when adjusting the strings.

Cucumbers should be grown at express rate in order to obtain the greatest possible number of good fruits from the plants. The plants must be afforded a light rich rooting medium to start in, and a uniformly hot and moist atmosphere, never, if possible, permitting the night temperature to fall below 70°, and allowing it to run up to 95° or 100°, with sun-heat, providing that such a temperature be accompanied with a moisture-charged atmosphere.

As soon as the roots are seen through the surface of the soil, lay on it a top-dressing of about 3 inches deep of good manure. Should stable-manure, including perhaps peat, moss-litter, or sawdust surcharged with ammonia, be used, the roof-ventilators should be left slightly open for a night or two to admit of the fumes arising from the manure consequent upon being placed in a high temperature to escape. The Cucumbers require frequent attention as to the pinching and training of the growths in order to maintain the plants in a vigorous, free-bearing condition up to the time they have to make way either for a fresh lot of plants or for Tomatos—say the middle of July—for yielding fruit during October, November, and early part of December. *H. W. Ward, Rayleigh.*

NEW HYBRIDS OF DODECANTHEON: "GYROSELLE," OR AMERICAN COWSLIP.

MONS. E. THIÉBAUT, of 30, Place de la Madeleine, Paris, exhibited at the summer show of the National Horticultural Society of France in 1897 no fewer than twenty-six named varieties of these pretty free-blooming hardy herbaceous plants of his own raising, which were much admired, and favourably noticed in the number of the *Revue Horticole* for

August 16, with an interesting descriptive article by M. Jules Rudolphe. Twelve of these varieties are now nicely in flower in pots in my greenhouse. Although perfectly hardy so far as frost is concerned, our long wet winters in the South of Ireland do not suit these plants, and if left in the open border they soon disappear, and rot away at the crown. They are well worth the trouble of pot-culture in a cold-frame, but will not stand forcing at all. The varieties now in flower with me are named as follow:—

D. multiflorum.—A most profuse bloomer, with nine spikes of small rosy flowers.

Sir Walter Scott.—Has one very strong, stout stem, bearing much the largest head of bloom of the lot. The flowers are white with a yellow centre, surrounded with a pretty rosy ring.

Longfellow.—One of the prettiest of the set, with large rosy-white flowers on two spikes.

Le Géant.—The tallest flower-stem of all, bearing a rather thin head of pretty rosy-white flowers. This was the first to open, and seems to be a very free seeder.

Clarinda.—Medium height, with two flower-spikes of pure white flowers with dark eye.

Snowflake.—A very strong grower, bearing four spikes of good-sized, pure white flowers with dark eye; quite one of the best of the lot.

Perfection.—An exceedingly pretty flower, of good size, of a pale rosy-lilac colour, with good yellow-and-black eye, edged with rose-colour. Two spikes of flower.

Donna Maria.—A good-sized flower, of a light rose colour, with large, distinctly-marked eye.

Mont Blanc.—A dwarf but strong grower, with pure white flowers, have a yellow and maroon eye.

Bucephalus.—A good large flower, with stem of medium height, and flowers of a light shade of rose colour, and a good distinct eye.

Vondel.—A medium-sized flower, of a deep shade of rosy-lilac. This is the second most profuse bloomer, and it bears five stems.

Rose Queen.—A rather tall, slight-stemmed variety, coming nearer to the well-known *D. media* than any other. *W. E. Gumbleton, Belgrove.*

SCOTLAND.

EDINBURGH BOTANIC GARDEN.

PRIMULAS.—The collection of these plants has always been an attractive one here, and of late years many additions have been made. For the past two years spots have been found for them on the rockery, where they are readily inspected, especially as arranged in clumps or patches convenient for comparison. Of those in flower recently I may mention the following:—*P. viscosa nivalis*, a large mass surmounting a piece of rockwork. This is most vigorous, the foliage being the picture of health, although scarcely visible for the masses of white flowers, nestling among the leaves. *P. v. decora*, a dark-flowered variety well represented, forms a strong contrast to the first named. *P. frondosa* is throwing up a quantity of pale lilac compact inflorescences from among the small silvery-foliage—a desirable plant for cultivating in pots for cool greenhouse decoration. The distinct *P. marginata* is also in quantity, the flowers are variable, and several varieties are grown, some of which are of light and others dark shades of blue. The flowers are raised but slightly above the foliage. *P. m. cœrulea* and *P. m. grandiflora* are also in bloom.

P. Auricula marginata is a very different plant to the last-named, having broad leaves with an entire margin, around which runs a line of the silvery meal common to *P. Auricula*. The type species is represented by a patch of about one yard across; it is a strong-growing plant, well worthy of cultivation. *P. viscosa* and its varieties are in flower. The variety *P. v. coccinea* is a distinct form, with dark-coloured flowers, though hardly possessing the

colour its name implies. *P. v. Balfouriana* and *P. v. decora* are also pretty plants. The dwarf-growing *P. minima*, a native of the Alps, has deeply-divided leaves, and the flowers rise just above the foliage; it is remarkable for its smallness, a number of the plants being required to form a large mass.

The brightest Primulas recently in flower are the Himalayan *P. rosea* and its variety *grandiflora*, the variety very dark, and more robust than the type. These are of easy culture in a damp soil, and deserve a place in any garden. *P. rosea* may be brought into flower a few weeks before its usual season by growing it in a greenhouse in the early spring, and it is then a most useful decorative plant. *P. Peyritschii* and *P. intermedia*, two hybrids, are deserving of notice, the latter with purplish flowers, the centre of which are yellow. Many others, such as *P. capitata*, *P. scotica*, *P. Stuarti purpurea*, and many more, will continue the series of this pretty spring-flowering genus, which commenced with a good display of *P. denticulata* and its forms very early this season, on account of the mildness of the winter.

VIBURNUM MACROCEPHALUM.

When in flower, this plant is sufficiently ornamental as a solitary lawn plant, or as a subject for training on a wall of a corridor, as is done here. Some of the inflorescences are more than 6 inches across, and of a pure white when fully open, but with a greenish tint when young, and somewhat like a monstrous Gueldres-Rose. It is sparse of foliage, and the peculiar habit of branching fits it exactly for training on a wall. Small plants in pots form nice decorative objects for the greenhouse, and the flowers last for several weeks. The plant does well in loamy soil, but is not of rapid growth.

ACIDANTHERA TUBULOSA.

This is a pretty spring-flowering Iridaceous plant, which is useful for the greenhouse, and differs from most garden flowers open at this season. It is a plant of easy culture, and prefers a rather heavy loamy soil. The corms are small, and a dozen or so in a 5-inch pot make a good display. The linear foliage, about a foot-high, is narrow with a thickish mid-rib, and above the leaves rise the flower-spikes which bear from two to five flowers of about 2 inches across, the segments having a pinkish tinge upon a white ground. The stamens are about half as long as the segments, and the anthers are violet-coloured. The plant is a native of the South-west parts of Cape Colony.

FERRARIA ANTHROSA.

The flowers of these remarkable plants are perhaps most attractive on account of their shape and peculiar colouring. The plant is a strong grower, and the flower-scape bears a succession of blooms of dull-purplish and brown tints, with the margins of the segments crumpled. The entire genus consists of half-hardy plants, which may be grown in any cool greenhouse or pit. All of the species (seven in number) are natives of the Cape Colony, with the exception of one which comes from Angola, viz., *F. Welwitschi*.

As pot plants, Ferrarias enjoy an abundance of water whilst growing, and a severe drying in a cool greenhouse from the time of the corms losing their leaves until growth recommences. The plants now in flower here have remained quite dormant for two years. *R. L. H.* [The above notes were written at the beginning of the month. Ed.]

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

MAY 10.—Present: Dr. M. T. Masters (in the chair); Mr. A. Sutton, and Rev. Professor Henslow, Hon. Sec.

Morchella, Species.—Some specimens were sent of a small species of this fungus, which appeared in a garden-bed; but the locality was not recorded.

Peas, Decayed.—Mr. Cooke, The Croft, Detling, Maidstone, forwarded some young plants of the American Wonder, which had failed to grow. They were sown last November, and while many are doing well, others close by became

sickly yellow color. Mr. Sutton observed that his experience was, that no wrinkled Pea, such as the above, was suitable for autumn sowing; the skin being more delicate than that of round Peas, will not stand the winter so well. This was, therefore, the probable cause of failure.

Freesia Bulbs Arrested.—Mr. F. Egbert Holland, Satis House, Yoxford, sent some bulbs which had been planted last July, had never thrown up any leaves, but had formed fresh bulbs upon the old ones, which had withered. It appeared to be a case common in Potatoes, when it is called super-tuberation, fresh tubers being formed at the expense of the old one. It was possibly due to the Freesia bulbs having been planted at the wrong time of the year, energy being expended in a wrong direction.

Cineraria Hybrids.—Mr. James, Woodside, Farnham Royal, Slough, sent a collection of hybrids raised between (*C. cruenta* × *Garden C.*) ♂ × *lanata* ♀. They were a small selection of a numerous progeny, the greater number of which were said to resemble the garden form; but the present ones had a tomentose stem, branches, and the under surface of the leaves, which last resembled in form those of *C. lanata*. The blossoms were rather small, some being a pure white, others mauve, and they were remarkable for their abundance. Unfortunately, the best plant with white flowers refuses to set much, if any seed; but it was hoped that Mr. James would persevere and try to establish a new race, which would certainly be attractive from the silvery appearance.

Begonia Leaves Diseased.—Mrs. Caddy, Lion Gate Gardens, Richmond, sent some leaves of these plants decayed round the margins. They were forwarded to Mr. W. G. Smith for further examination.

TULIP EXHIBITION AT THE ROYAL BOTANICAL GARDENS.

MAY 11.—This exhibition was held in connection with the first summer show of the Royal Botanic Society, and was small in extent and not conspicuous for good quality, and this due not to any fault of the exhibitors, but to the weather, which had been such that it was not possible for the flowers to expand fully by the above date. Many of the blooms staged had been placed in heat to expand after being cut, and they showed traces of the process. A week or ten days later would have made all the difference. The flowers were staged in the annexe to the large tent where they could be seen to the greatest advantage. There were four collections of twelve Rectified Tulips, the 1st prize of a Silver Cup was awarded to Mr. A. CHATER, Cambridge, who had of feathered bizarre, R. Headly and Masterpiece, flamed bizarre Samuel Barlow and Orion, feathered bybloemen John Linton and Sarah Headly, flamed bybloemen Duchess of Sutherland and Mrs. Jackson, feathered roses Modesty and Guido, flamed roses Glory of Stapleford and one unnamed; 2nd, Mr. A. D. HALL, Wye, Kent, his best flowers were flamed bizarre Sir Joseph Paxton and R. Yates, feathered bizarre Duke of Devonshire, flamed bybloemen Conningsby Castle and Duchess of Sutherland, flamed roses Annie McGregor; 3rd, Mr. C. W. NEEDHAM, Royton, Oldham; 4th, Messrs. BARR & SONS, King Street, Covent Garden.

With six varieties, Mr. J. W. BENTLEY, Stakehill, Manchester, was 1st, having feathered bizarre Wm. Wilson, flamed bizarre Lord Stanley, feathered bybloemen Bessie, flamed bybloemen Adonis, feathered rose Comte de Vergunces, flamed rose Annie McGregor. Mr. A. CHATER was 2nd, and Mr. C. W. NEEDHAM 3rd. The following class for six varieties did not fill, nor that for three feathered Tulips; and while all the flowers staged in the various classes were poor in quality, the feathered varieties were particularly so. Mr. J. W. BENTLEY had the best three-flamed varieties, staging bizarre Lord Stanley, bybloemen King of the Universe, and rose Mabel.

The first of the Samuel Barlow Memorial Prizes, consisting of a special Silver Medal, for a pair of rectified Tulips, was won by Mr. J. W. BENTLEY, who had feathered bizarre Duke of Devonshire and flamed bybloemen San Josef; Mr. A. D. HALL took the 2nd prize with flamed bizarre Sir J. Paxton and feathered rose Comte de Vergunces.

The premier Tulip was feathered rose Industry, shown by Messrs. BARR & SON; and the premier flamed Samuel Barlow staged by Mr. CHATER.

The Breeder Tulips, though limited in quantity and small in size, were striking, especially some of the roses. Mr. A. D. HALL was 1st with six, his southern locality evidently favouring him; Messrs. BARR & SON were 2nd; and Mr. J. W. BENTLEY 3rd. Mr. J. W. BENTLEY had the best three; Mr. C. W. NEEDHAM was 2nd.

NEWCASTLE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT.

MAY 11.—The monthly meeting of this Society was held at 25, Westgate Road, on the above date. There was a large attendance of members, and Mr. JNO BULLOCK presided.

Special Certificates were awarded to Mr. JAS. NICHOLSON, Ashfield Towers, Gosforth, for a collection of *Schizanthus*; and to Mr. JAS. RENWICK, Oakwood, for a collection of *Polyanthus*. Mr. MURRAY, of Oakwood, read an excellent paper entitled, "Hardy Trees and Shrubs in Landscape Gardening," which was followed by a discussion, in which many took part.

ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.

MAY 14.—The monthly meeting of the above association was held at Newport on the above date, Dr. J. Groves, B.A., J.P., presiding over a large attendance of members. Mr. A. Key gave an interesting and instructive experimental lecture on "Plant Foods: their Detection in Vegetables and Soils." After a few preliminary remarks respecting plant-foods, Mr. Key took "Phosphates" as the subject for the evening, and showed by experiments that seeds and fruits contained large quantities of phosphates; and also showed how to ascertain its presence in soils and manures. An unanimous vote of thanks was accorded Mr. Key for his valuable lecture.

Various exhibits came from Mr. G. Nobbs, gr. to HER MAJESTY at Osborne; Mr. J. Nicholas, gr. to Mrs. GRAY, Kintore, Sandown; and Mr. J. J. Lemington, gr. to Dr. COOMBE, Newport. The first excursion of the season took place to Appley Towers and St. John's Vicarage, Ryde on May 19.

READING & DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

MAY 16.—The first meeting of the summer season was held on the above date, when the chairman of the Association, Mr. Turton, presided over a good attendance of members.

The subject for discussion was Hardy Flowers, including Shrubs and Bulbs. This was introduced by Mr. Townsend, gr. to Sir WILLIAM FARRER, Sandhurst Lodge, who said that he should refer principally to those varieties which made the garden look gay during the early months of the year, and only those which were grown in the garden under his charge. The following varieties were touched upon:—Flowering shrubs, Amygdalis, Abelia, Andromeda, Buddleia, Berberis, Cydonia, Cerasus, Crataegus, Ceanothus, Choisya, Cytisus, Carpentaria, Chimonanthus, Calycanthus, Cistus, Cornus, Deutzia, Daphne, Diplopappus, Chrysophyllus, Escallonia, Forsythia, Garrya elliptica, Genista, Iberis, Jasmine, Kerria, Laburnum, Leycesteria formosa, Ledum, Mespilus, Magnolia, Nuttallia, Pyrus, Prunus, Philadelphus, Ribes, Spiraea, Sambusa, Ulex, Viburnum, Veronica and Weigela. Bulbs: Hyacinths, Tulips, Narcissus, Crocuses, Aconit, s, Chionodoxa, Triteleia, Scilla, Grape Hyacinths, Alliums, Ornithogalum, Leucojum, Dog's-tooth Violets and Trilliums. Flowers (flowering from February till the early part of May: Hebeborus, Violets, Arabis, Aubrietia, Daisies, Wallflowers, Myosotis, Primroses, Polyanthus, Alyssum, Doronicum, Alpine Phlox and Primula Sieboldi. A discussion followed. An interesting feature of the meeting was the large display of cut-flowers, including Primula Sieboldi, Daisies, Myosotis, Tulips, Trilliums, Pansies, Lily-of-the-Valley, Wallflowers, Narcissus, Auriculas, Honeysuckles, Roses (outdoor growth), &c. These were contributed by Mr. TURTON, Maiden Erlegh Gardens, Mr. W. Smith, gr. to Miss NEILD, Greenbank, and Mr. TOWNSEND, the latter exhibiting also a splendidly-grown Anthurium, showing forty-five spathe.

HORTICULTURAL SHOW AT THE ALEXANDRA PALACE.

MAY 18, 19, 20.—An exhibition was opened on Wednesday last at the Alexandra Palace, Wood Green; Mr. R. Dean acting as Secretary and Superintendent.

There were fourteen classes, but only in one of these was there competition, while in several others there was no exhibit at all, yet the plants and flowers that were staged were for the most part of good quality, and being arranged in the Central Hall (a miniature Crystal Palace), they could be very conveniently inspected. A fully satisfactory exhibition could hardly have been expected, in view of the fact that the proximity of the Temple Show of the Royal Horticultural Society and the Manchester Show, was so evident at the last meeting held in the Drill Hall. The Alexandra Palace, too, after being closed for some nine years previous to its re-opening last Easter, has its reputation to win, and if it is to be a success as a public pleasure ground and resort, very much work must be done before it can present anything like a smart appearance. Nevertheless the buildings and grounds would appear to possess vast capabilities, and it will be a pity if these are not turned to account in some shape or form.

The group of flowering and foliage plants upon a central ground space of 250 feet, was from the nurseries of Messrs. JOHN FEED & SONS, Roupell Park, Norwood Road, London, S.E., and was a worthy exhibit. It included finely-grown Cordylines, a few Caladiums, Palms, Ferns, and a fine lot of flowering plants, among which, were single and double flowered tuberous Begonias, Boronias, Ericas, &c. Messrs. FEED had 1st prize too for nine fine foliage plants.

The only group of Orchids in flower was one from Mr. Geo. Cragg, gr. to W. C. WALKER, Esq., Percy Lodge, Winchmore Hill, N. In this group we noticed several good forms of *Odontoglossum crispum*, and some finely-flowered plants of *Oncidium Marshallianum*. Mr. CRAAG was also an exhibitor of twenty-four bunches of cut flowers, several of these being Orchids.

The 1st prize for a collection of cut flowers was taken by Mr. AMOS PERRY, Hardy Plant Farm, Winchmore Hill,

London, N., and naturally the flowers were from the outdoor garden, a number of varieties of *Iris pumila* being conspicuous. In addition to these were flowers of some of the showier hardy plants, including a few pretty hybrid Geums.

For Roses, Mr. GEO. MOUNT, of Canterbury, had 1st prizes in two classes, in one case showing twelve blooms, and in the other twenty-four blooms. Catherine Mermet was the variety in best condition, and a bloom of Bridesmaid was quite of noticeable quality.

The class for three Bouquets was the only one that was competed. In this case there were three exhibitors, and Messrs. PERKINS & SONS, Coventry, were decidedly 1st, each of the bouquets being in the best taste.

NON-COMPETITIVE EXHIBITS.

Mr. S. MORTIMER, Rowledge Nurseries, Farnham, obtained a Gold Medal for a capital lot of Cucumbers and Tomatoes, five or six Cucumber fruits of each of the following varieties being staged:—Sutton's A 1, Rochford's Market, Sutton's Peerless, Improved Telegraph, Lockie's Perfection, Epicure, Pride of the Market, Matchless, and Progress. The ten boxes of Tomatoes represented the varieties Conqueror, Conqueror Improved, Abundance, and Mitchell's Hybrid.

Mr. L. H. CALCUTT, Fern Bank Nursery, Stoke Newington, had some pretty table decorations, in which blooms of Spanish Irises were a conspicuous feature. Mr. J. WILLIAMS, 4A, Oxford Road, Ealing, also exhibited table decorations.

A large Gold Medal was awarded Messrs. W. CUTBUSH & SONS, Highgate Nurseries, London, for an interesting circular group of choice flowering and foliage plants arranged upon the floor of the hall. This included Azaleas, Ericas, Hydrangeas, and other species that Messrs. Cutbush always exhibit creditably.

A table was furnished with succulents by Mr. GEO. BOURNE, Grove Villa, High Road, New Southgate, N., the only plants in bloom being *Phyllocactus* and *Echinopsis Pentlandi*.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, had a gay group of flowers upon a table, special features in which were *Rhododendron* blooms of varied tints, Tulips, and sprays of Azalea mollis.

From Mr. THOS. S. WARE, Hale Farm Nurseries, Tottenham, was a very large exhibit of hardy flowers and hardy plants in flower, the latter being shown, for the greater part, in pans. Those filled with *Primula involucrata*, *Ramondia pyrenaica*, *Anthemis Aizoon*, *Saxifraga Camposii*, *Doronicum Clusii*, *Geum coccineum plenum*, *Dodecatheon splendens*, and *Darlingtonia californica*, were most noticeable.

Messrs. WOOD & SON, of Wood Green, had little difficulty in making a display of garden requisites at a spot so near their headquarters. This they did, and the table representing the firm overflowed with articles of necessity to the gardener, including many of their specialties.

Messrs. W. EDWARDS & SON, Nottingham, exhibited ornamental vases for Ferns and similar plants; and another table was devoted to a display of Ichthemio Guano.

MARKETS.

COVENT GARDEN, MAY 19.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

Horseradish, foreign per bundle	0 9-1 0		
— Cheshire (loose), p. doz.	2 0—		

REMARKS.—The shelled Pea merchants are now getting busy, the ruling price is about 2s. per quart. Asparagus, home-grown, in large quantities are coming, but only of ordinary size, nothing to command high price. Broccoli and Cabbage are still plentiful and prices low. Spring Lettuce and Spinach are soon to arrive, then good-bye to the winter sorts. Gooseberries are coming now in sieves, and prices may reasonably be expected to become lower before the week ends; any really fine specimen fruits now command good prices. The South Australian Apples are certainly finer than Tasmanian. Some Wellingtons I saw from South Australia looked a fine luscious fruit, of good size, and more like dessert than culinary. The St. Michael Pines are plentiful, well-grown, fine fruits.

POTATOS.

Supplies of old Potatoes rather more limited, and prices have tightened a shade. Dunbar Maincrops, 150s. to 155s.; other Ware, 120s. to 140s. per ton. Foreign Ware, 4s. 6d. to 6s. per bag; Jersey New Potatoes, 18s. to 20s.; Lisbon, 10s. to 11s.; Malta and Canary Kidneys, 14s. to 17s.; Malta Rounds, 12s. per cwt. John Bath, 32 and 34, Wellington Street, Covent Garden, W.C.

SEEDS.

LONDON: May 18.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that to-day's seed market, as is usual at this time of the year, was very thinly attended, with but little business doing. Sowing orders are now about over. More money is asked in Germany for White Clover seed. White Mustard seed, in consequence of some export orders coming to Europe from America, is dearer; the Californian Mustard crop is said to be a failure. Rape seed keeps steady. There is no change this week in Bird-seeds. Florida Velvet Beans realise 2s. per lb. Full prices are asked for Peas, Haricots, and Lentils. The Board of Trade Returns give the imports of Clover and Grass seeds into the United Kingdom for the four months of this year, ending April 30, 1898, as 203,798 cwt., value £395,664, as against 162,067 cwt., value £320,165, for the corresponding period of 1897.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending May 14, and for the corresponding period of 1897, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1897.		1898.		Difference.
	s.	d.	s.	d.	
Wheat	27	11	45	11	+ 18 0
Barley	20	2	27	1	+ 6 11
Oats	17	1	21	1	+ 4 0

(Remainder of Markets carried forward to p. xi.)

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named: and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending May 14, is furnished from the Meteorological Office:—

"The weather during this period again was very changeable, frequent showers or steady rain alternating with intervals of clear sky. Thunder and lightning were experienced in some parts of north-eastern and south eastern England on Thursday.

"The temperature was just equal to the mean in 'England, S.' but below it in all other districts; the deficit was slight generally, but amounted to 3° in 'Scotland, E.,' and to 5° in 'Scotland, N.' The highest of the maxima occurred during the earlier days of the period, and ranged from 69° in 'England, S.' (at Southampton), to 59° in 'Scotland, N.' The lowest of the minima, which were recorded on the 13th, ranged from 26° in 'Scotland, N.,' 28° in 'Scotland, E.,' 30° in 'England, N.E.,' and 31° in Ireland, to 34° over the central and western English districts, and to 41° in the 'Channel Islands.'

"The rainfall was more than the mean in all districts excepting 'England, N.E.' The excess was very slight over the eastern and central parts of Great Britain, rather considerable in most other places, and large in 'England, S.,' the 'Channel Islands,' and 'England, N.W.'

"The bright sunshine just equalled the mean in 'England, N.W.' and 'Scotland, W.,' but was less in all other districts, the deficit being most striking in 'England, E. and S.,' and the 'Channel Islands.' The percentage of the possible duration ranged from 37 in 'England, N.W. and S.W.,' to 29 in 'England, N.E. and E.'"

GARDENING APPOINTMENTS.

Mr. W. LEECH, for the past three years Foreman in the Garden, Ramsey Abbey, Huntingdon, as Gardener to Sir RALPH HARE, Gressen Hall, Norfolk.
Mr. WM. KITCHEN, for the past two years Foreman in the Gardens at Moor Park, Farnham, Surrey, as Gardener to Mrs. JOHNSTON FOSTER, at the same address.
Mr. ARTHUR W. WITT, for the past six years Gardener at Portobello House, Kingsdown, Sevenoaks, as Gardener to CECIL DREW, Esq., The Mole House, Hersham, Walton-on-Thames.

CATALOGUES RECEIVED.

ISIDOR SCHOPFER, Linz-on-the-Danube, Austria—Seeds, Roses, Palms, &c.
W. J. GODFREY, Exmouth, Devon—New Winter-flowering and Tree Carnations; also, American varieties.

AZALEA MOLLIS: W. B. Something is wrong with the method of cultivation pursued. Perhaps they have lacked water at the roots, and that this is the cause of the buds dropping.

CUCUMBERS TURNING YELLOW AT THE TIPS: Ocon. The result of a check to growth—which may be due to a variety of causes.

DENDROBIUM CARINIFERUM: Veritas. Grow the plant in a warm moist house until the growths are completed, then place in a cooler and more airy one until the growing season comes round again.

EARWIGS IN A SEASIDE BUILDING: A. B. B. You might find Richard's X L All serviceable in ridding the house of these creatures. For his address con our advertisement columns. It will not injure any plant, but it must not be inhaled.

GRAPES: R. K., Epsom. The berries are affected by rust, which may have been caused by the young berries having been touched by something, or more probably by cold draughts. The berries will remain permanently disfigured.

INSECTS: J. A. Myriapods injurious to plants. Trap them with slices of Carrot.

MELONS AND STRAWBERRIES: W. B. The first named would not give satisfactory results in a greenhouse. It needs bottom heat of not less than 80°, and much top heat. Strawberries to ripen in May and early June would give good returns if placed in a light position in a greenhouse.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—F. B. We cannot be sure of the identity of your plant from the specimen received. If you have any others, let them grow for a time.—W. F. Olearia Gunniana.—R. H. N. The varieties of hybrid Rhododendrons are so numerous we cannot undertake to name them. Send to some nurseryman who grows these plants largely.—F. A., Norwich. The plant from Darjeeling is Cymbidium Devonianum.—W. C. B. The yellowish-white flower is Miltonia flavescentis; the other a small Dendrobium crepidatum. Neither is of any special value, though both are pretty garden plants.—C. W. D. The shoots sent are those of Cytisus præcox. C. præcox came up in a bed of seedlings of C. purgans at the Warminster Nurseries, and probably is a cross between that species and C. albus; see Gardeners' Chronicle, May 22, 1897, p. 340.—Bucks. The Orchid is Lælia purpurata; the other specimen, Biota Sieboldi.—M. W. 1, Bifrenaria tyrianthina; 2, Pleurothallis longissima; 3, Acalypha marginata; 4, Aralia Guilfoylei; 5, Anthericum lineare variegatum; 6, a form of Adiantum capillus-veneris; 7, Campylobotrys regalis.—J. B. Prunus Padus (Bird Cherry).—Gardener. 1, Phlox subulata; 2, Lithospermum fruticosum; 3, Phlox subulata frondosa; 4, the small blue flower is Veronica saxatilis; 5, Polypodium dryopteris; 6, Phlox reptans.—S. L. 1, Ornithogalum arabicum; 2, Doronicum plantagineum.—L. P. 1, Sedum carneum variegatum; 2, Poa trivialis variegata; 3, Mercurialis perennis; 4, Crataegus cordata; 5, Juniperus sinensis.—W. J. G. The Cattleya Mendeli is a good ordinary form; the C. Mossii a very distinct and uncommon variety.—G. C. The Fern is Polystichum angulare proliferum; the yellow flower, Celsia cretica. So far as we can judge by the withered shoots sent, the other is an Ampelopsis.—C. A. B. We are

unable to name your plants with certainty in the absence of flowers.—L. V. B. K. Spiræa confusa.

PEACH-TREES: Oakfield. The immediate cause of the curling of the leaves is a fungus, Ascomyces deformans, and it is usual for such deformed leaves to be infested by mildew. The worst of them should be cut off and forthwith burnt, and then the trees should be well syringed with water in which sulphide of potassium has been dissolved to the amount of ½ oz. to a gallon of water. Failing this, you might apply black sulphur—S. vivium. If the trees do not seem to be in a thrifty condition, and they are not aged, transplant them in the autumn into new soil, loam, mortar-rubble, and well-decayed stable manure. The drainage of the border should be carefully inspected and made efficient if found to be faulty. The lime you suggest applying forthwith will be beneficial. Everything should be done to encourage growth during the next two months.

PEAS: Walton. Can you send some specimens of the insects which you suspect have been the cause of the injury to the plants? The stems of some of them appear as if gnawed just below the ground-level, and many of the roots are decayed.

PINE CONES: A. B. B. If the cones are placed in the sun, or on the kitchen range when the fire has gone out an hour or so, the scales will readily open and allow the seeds to be beaten out. Doubtless you have gardening friends who would supply the cones if asked so to do.

ROMAN HYACINTHS, ETC.: P. S. C. We are unable to name any French growers of the plants you name.

SUPPOSED CROSS BETWEEN CYTISUS SCOPARIUS VAR. ANDREANUS AND C. PRÆCOX: T. Geeson. The shoo's sent are those of Caragana arborescens.

TOMATOES SPOTTED: A. F. Cladosporium lycopersici, the so-called "black spot" of the Tomatoes. Burn forthwith every affected fruit, and dress the plants with sulphide of Potassium-wash at the rate of ½ oz. to 1 gallon of water.

TULIPS DISEASED: G. Dance. The Tulips sent are a very bad case of attack by a fungus identical with, or nearly allied to, the Sclerotium-disease, described by Mr. Massee in the Gardeners' Chronicle, p. 160, vol. xvi., 1894. The fungus is abundant in leaves and flowers, causing the spotting and death of all parts above ground. Black, hard, shining grains, the sclerotia, are common, especially in rotten flowers, and show that the fungus has run its course, and entered into a resting-stage till next season. Old bulb-sheaths have also been attacked, but the new bulbs seem, as yet, untouched. The "worms" are millipedes, which we do not think have anything to do with causing the disease, although now they are assisting the destruction. The fungus may have been brought with the bulbs, or it has arisen from resting sclerotia accumulated in the beds from former bulbs. The case is a bad one, and has been allowed to go too far, if as, you say, 80 per cent. of the plants are a failure. We should get rid of the whole lot by removing and burning them; and on no account digging them in. The ground should do well enough for summer bedding-plants, if these do not include Lilliums or other plants allied to Tulips. We should, however, prefer to replace the top few inches of soil with clean, fresh loam. This is absolutely necessary if you mean to try Tulips or Hyacinths in the same plots next season; the better plan would be to keep plants of the Tulip kind away from the beds for a year at the least. W. G. Smith.

VANDA: B. S. W. & Son. Thanks for abnormal flower of Vanda, which we will examine carefully.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper, MORE THAN DOUBLED, and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, and ALL CLASSES of GARDENERS and GARDEN-LOVERS at home, that it has a specially large FOREIGN and COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

THE

Gardeners' Chronicle.

SATURDAY, MAY 28, 1898.

RECENT BOTANICAL DISCOVERIES IN NEW ZEALAND.

A LITTLE more than two years ago I contributed (*Gardeners' Chronicle*, Jan. 11, 1896, p. 43) a summary of recent botanical discoveries in New Zealand and the outlying small islands, and I now propose giving a brief account of what has been done since, together with references to some facts previously overlooked by me. The twenty-ninth volume of the *Transactions of the New Zealand Institute*, and the previous volume, are the principal sources of what follows.

In the first place, I should like to correct a statement made in my article referred to above. I mentioned there that 550 assumed new species of flowering plants had been added to the flora since the appearance of Sir Joseph Hooker's *Handbook*, published thirty years previously, but only one new genus, *Tetrachondra*, an inconspicuous and anomalous little plant referred to the *Boraginaceæ*. This is not quite true, because I had forgotten *Siphonidium*, a genus allied to *Euphrasia*, but differing greatly in habit and structural details; only a single species is known. It is a very small trailing plant, having oval leaves a quarter of an inch long, and solitary, axillary erect flowers, and exceedingly slender corollas about 3 inches long. There is little doubt, however, that *Siphonidium* is a congener of Sir Joseph Hooker's section *Anagosperra* of *Euphrasia* (*Hook. Ic. Pl.*, pl. 1283), recently raised to generic rank by Wettstein.

Taking the 28th volume, issued last year, first, we find some interesting records; among them the re-discovery of *Dactylanthus*, a curious endemic genus of the *Balanophoraceæ*, and the discovery of *Lepilæna bilocularis*, a new species of a genus of *Naiadaceæ* confined to Australia and New Zealand. Mr. Thos. Kirk's paper on the displacement and replacement of native plants in New Zealand I summarised in the *Gardeners' Chronicle* of June 13, 1896, p. 731. There is a second and later paper by the same author on introduced plants, which is entitled "The Products of a Ballast-heap." It was the ballast of a ship from Buenos Ayres, and covered an area of about 40 feet by 80. One hundred and four species of plants were collected, twenty of which had not previously been observed in the colony. But the interest lay in the fact that the majority of the new-comers were of South American origin, because previously less than a dozen of the vast number of naturalised plants were natives of that part of the world. Of course, it remains to be seen whether they will permanently establish themselves; but so far as our experience goes, and speaking generally, European weeds are the most vigorous as colonists. The worst of it is, almost all of them are useless

and injurious, and over-run new countries at an alarming pace. But having already enlarged on this subject, I may pass on to the new plants described by Mr. Kirk, Mr. Cheeseman, by the veteran Rev. W. Colenso, and others. *Cordyline Cheesemani* is the most noteworthy among the genera characteristic of the country. Twelve species are added to the seventy, or thereabouts, previously-known native species of *Veronica*, partly from new discoveries, and partly from the fact that several plants originally referred to the genera *Logania* and *Mitrasacme* prove to be *Veronica*.

Mr. Colenso describes between thirty and forty reputed new species, belonging to a great number of different genera; but as he takes an exceedingly narrow view of species, the majority of them are not likely to meet with general acceptance. Many of the New Zealand genera, like *Rubus* and *Hieracium* with us, present such a multitude of forms that to be consistent one must either make a large number of species, with little range of variation, or a small number of species exhibiting a considerable range of variation. The former course renders it impossible for anyone except a specialist to identify "species," and even the specialists often disagree. But this is a digression. I will now pass to the consideration of the botany of the twenty-ninth volume of the *Transactions*.

Foremost in interest, perhaps, is Mr. T. Kirk's paper on the botany of the East Cape district, as it was in this district that Sir Joseph Banks and Dr. Solander, who accompanied Captain Cook on his first voyage, and who were the first naturalists to visit New Zealand, collected. They landed at Poverty Bay in October, 1769, and subsequently visited other localities, and made a collection of the lowland plants to the number of 250 species. As Mr. Kirk relates, about seventy years elapsed before another naturalist visited this part of the Colony. In 1838 the Rev. W. Colenso paid his first visit to East Cape; but what is more remarkable, he is still in the enjoyment of good health, and attended every meeting of the Hawke's Bay Philosophical Institute in 1896, during which year he occupied the presidential chair.

But to return to the East Cape District. This comprises the country extending from Opotiki, Cape Runaway, 37° 30' S., and the East Cape to the Mahia Peninsula, in 39° 15' S. latitude; thus being bounded on all sides by the sea except the west, where it runs into the vast forest-clad district, known as the Urewera country. The mountains culminate in Hikurangi, a peak 5606 feet high. Large portions are still covered with dense and luxuriant forest, of which *Vitex lucens* is an important constituent in the northern portion of the district. The Kauri (*Dammara australis*), characteristic of the coast forests from Mercury Bay northward is, however, totally absent.

Mr. Kirk's catalogue of flowering plants and Ferns comprises about 500 species; but he anticipates that future explorations will raise the total to 650 or 700, the additions consisting almost exclusively of flowering plants. Strange to say, the number of endemic species does not exceed half-a-dozen.

The chief interest of the district arises, Mr. Kirk points out, from its having a remarkable intermixture of plants characteristic of the extreme north of the colony, associated with others of a peculiarly southern type. For example: *Pisonia* and *Euphrasia*, *Sideroxylon* and *Aciphylla*, *Persoonia* and *Gentiana*, and *Vitex* and *Calceolaria*. It is also estimated

that the number of species attaining their northern or southern limits within its boundaries is, perhaps, larger than in any other district of similar area in the North Island.

Mr. Kirk gives a list of sixteen northern species which attain their extreme southern limit, and fifty-five southern species which attain their extreme northern limit, in the East Cape district. In all these statistics only flowering-plants and Ferns are included. An analysis of the general list would obviously have very little interest for persons not fully conversant with the flora of New Zealand; but it may be mentioned that all the species collected by Banks and Solander are indicated, and there are interesting and important notes to some of the plants. *Clianthus puniceus*, which has now become exceedingly rare, was originally discovered by Banks and Solander at Tolago and Tigadu; and Kirk states that Bishop Williams informed him that it is still found at Anaura, and on one or two small islands in the vicinity; also inland. This locality is not far from Tolago. Mr. Kirk does not question the *Clianthus* being truly wild in this part of New Zealand; and Sir Joseph Hooker, in his *Handbook*, does not say that it is not wild, though it is mostly found near native dwellings; yet I have somewhere seen it stated that it cannot be regarded as truly wild in any of the localities recorded.

It is a remarkable fact that the original and far more gorgeous species of *Clianthus* was one of the few plants brought by Cook's predecessor, Dampier, after whom it was named.

Among Mr. Kirk's other contributions is one on that small group of *Leguminosæ* of which *Carmichaelia* is the type; a group with one exception in Lord Howe's Island, restricted to New Zealand, where, I may add, there are not half-a-dozen other native *Leguminosæ*. Ten species of this group are described in Hooker's *Handbook* (1864) belonging to two genera, and these numbers are now increased to twenty-six and four respectively. The genera are, *Carmichaelia*, *Notospartium*, *Corallospartium*, and *Huttonella*; the two latter partly founded on species formerly placed in the first, and the last described in the paper under review.* *W. Botting Hemsley.*

NEW OR NOTEWORTHY PLANTS.

LILIUM RUBELLUM, Baker.†

THIS fine Lily is quite new to cultivation, and to European botanists, although it is well figured in the *Hozo Zufu*, vol. 51, tab. 6. It is nearest to *L. japonicum* (Krameri), from which it differs by its broad speciosum-like leaves and smaller pink flowers, with obtuse segments (see fig. 128, p. 335). A stock which was imported from Japan by Messrs. Bunting & Son, of Colchester, has, we understand, passed into the hands of Messrs. R. Wallace & Co., who exhibit it at the great Temple Show. A drawing has been made for the *Botanical Magazine* from flowering-specimens supplied by Messrs. Bunting.

Bulb globose, with lanceolate scales; stem slender,

* Since the foregoing was written, the death of Mr. Thos. Kirk has occurred (see *Gardeners' Chronicle*, March 18, p. 175), and I learn from Mr. Cheeseman that it is feared that his *Student's Flora of New Zealand* is left in a far from complete state. *W. B. H.*

† *Lilium* (*Eulirion*) *rubellum*, Baker. — Bulbo globoso squamis lanceolatis; caule gracili striato; foliis circiter 20 alternis lanceolatis obscure; petiolatis viridibus glabris 5-7-nerviis; floribus 1-2 erecto palembus; perianthio infundibuliformi pallide rubello, segmentis oblanceolato-oblongis obtusis extus basi viridi tinctis, interioribus latioribus; staminibus perianthio duplo brevioribus; stylo arcuato staminibus longiori.

terete, green, bearing about twenty alternate obscurely-petioled bright-green lanceolate leaves, the central ones the largest, about 2 inches by $\frac{3}{4}$ -inch broad, conspicuously 5-7-nerved; flowers 1-2, erect-patent; perianth openly funnel-shaped, pink, unspotted, nearly 3 inches long, 3 inches in diameter when fully expanded; segments oblanceolate-oblong, obtuse, the inner an inch broad, the outer narrower, slightly tinged with green towards the base; stamens less than half as long as the perianth; anthers small, linear, bright yellow; style arcuate, overtopping the stamens. *J. G. Baker.*

ALPINE GARDEN.

PRIMULA DENTICULATA AND ITS VARIETIES.

NUMBERS of this pretty Himalayan species and its varieties are now in flower at Woking, and although the species cannot be considered a new introduction, it and they are not so plentiful in gardens as their easy culture and abundant blooming habit at this season of the year warrant. The flowers, of a bright lilac colour, are small, and appear in dense heads borne on the top of stout stems 8 inches in height. The leaves are in shape oblong lanceolate, with a white farina beneath. The species and its varieties do well if planted out in loamy soil in a moist situation; and when thus treated are not injured by any amount of bright sunshine. The plants are increased by division of the crowns during the autumn and by seeds, which should be sown as soon as ripe. One of the best varieties is *P. denticulata alba*, an exact counterpart of the type excepting in colour. It is a very valuable addition to spring flowers, white flowers being scarce at that season. This variety was introduced in 1886.

P. d. var. Cashmeriana is a form of the type which comes from Cashmere, as was introduced in 1879. The flowers are of a light purple, but with a clear yellow eye, and are more densely arranged than in the type. The leaves are of an oblong shape, and in colour pale green, and they have a bright yellow mealiness on the lower side. This variety is described in the *Floral Magazine*, new series, p. 360; and in the *Revue Horticole* for 1880, p. 330.

P. d. var. pulcherrima is an improved form of the type, with long leathery leaves, and grows nearly 1 foot in height. The globular flower-heads are much larger, and its flowers are much deeper in colour, and the meal on the under-surface of the leaf is not so abundant as in the other forms of the species.

P. d. var. purpurea is the darkest form, and it was introduced from the Himalayas in 1873. The flowers, densely clustered, are borne on stems about 8 inches in height, and are of a deep purple colour. All of these forms are as floriferous as the type, and quite hardy, and equally good for growing in pots for greenhouse decorations. *E. S., Woking.*

Primula verticillata.—This, the well-known Abyssinian Primrose, is a glorious subject for flowering at this season of the year. A highly valuable greenhouse species, it deserves all the attention which can be given it, for in addition to its very handsomely mealed foliage, it flowers with great freedom, putting forth scapes, each of which bears two or three whorls of bright yellow blossoms, which possess the perfume of the Cowslip. It is a plant that finds a ready sale when in bloom, and good use was made of it at the recent spring show at Brighton, as it held a foremost place in groups. As it seeds fairly plentifully, and the grains germinate freely, it is readily propagated in this way, though seedlings show but little variation. A more desirable species to cultivate can scarcely be named; one of its leading recommendations is that it flowers so early in spring. *R. D.*

ASH ANALYSIS AND THE MANURING OF PLANTS.

SINCE Liebig first proposed to manure each crop by adding to the soil various mineral matters removed by a normal crop, the theory that the most suitable

manure for a particular plant can be learnt from an analysis of the ash of the plant, has never been entirely dropped, and though the Rothamsted experiments and the experience of more than a generation of farmers working with artificial manures have amply disproved it for our standard farm crops, it still finds a place in garden literature.

Year by year analyses of plants are accumulated, separate determinations are even made for the root, the leaves, and the fruit, and this or that combination of manures is recommended as supplying exactly what the plant removes from the soil; yet in the only cases where exact and long-continued experiments have been made, Wheat, Oats, Barley, Swedes, Mangels, Potatoes, Clovers, and Grasses, we find that the manure giving the best returns in the crop is very far from that indicated by an analysis of the plant. In many cases the constituent most required by the plant is not the substance chiefly removed from the soil, but the one of which the least proportion is taken; the plant from its habit of growth finds a difficulty in obtaining the substance in question from ordinary soil, and is always deficient in it, given a free supply in the shape of manure the plant is proportionally stimulated. For example, Wheat is specially responsive to dressings of nitrogenous manure, though it contains a comparatively small proportion of nitrogen; but feeding as Wheat does chiefly during the cooler part of the year, and being a deep-rooting plant, it is not well fitted to obtain the nitrates which develop in the surface-soil, and hence requires a free supply of nitrogen in the manure.

To obtain a little more evidence on this question, two students of the South-Eastern Agricultural College at Wye, D. Turner and H. F. Bengel, undertook the examination of certain plants as set out below. In the first place the composition of any specific plant is more than a little variable, according to the soil and other conditions under which each individual is grown, the variations between individuals being often as great as those between species—in any case, far too great to permit one to draw deductions from an average of the analyses. It is easier to draw conclusions as to the requirements of soils by analyses of the plants that grow in them, than to decide upon the needs of the plant generally from the same data.

To arrive at some idea of the variations that occur in the composition of a plant growing naturally, the Dandelion was selected and examined by D. Turner; specimens were collected from the various soils to be met with near Wye, two or three being taken from each place; the whole plants in late autumn were dug up, washed till free from soil, dried, incinerated, and the proportions of lime and phosphoric acid in the ash determined. For the purposes of our enquiry it was not necessary to perform a complete analysis, one or two elements being enough to show the essential variation or fixity of the whole.

The results set out below show the percentages of lime (CaO), and the phosphoric acid (P₂O₅) in the ash, these percentages being further recalculated in the last two columns on the basis of making the average percentage = 100.

Dandelions, D. Turner.

NATURE OF SOIL.	Lime in Ash.	Phosphoric Acid in Ash.	Lime.	Phosphoric Acid.
Sandy Loam ...	12.8	2.5	46	38
Brick-earth by river-side ...	14.6	10.0	52	151
Reddish sandy loam ...	21.9	5.8	89	88
Rich loam ...	27.4	8.9	98	135
Chalky railway bank	39.8	7.3	142	111
Broken chalk by roadside ...	48.8	4.9	174	74
Average	28.0	6.6	100	100

The variations are plainly very great, nor is there any connection direct or inverse, between the two constituents; again, the phosphoric acid determination nearest to the mean value is as much as 11 per cent. less than the average, so little trust could be placed in a manure based upon the average values.

The second set of determinations were designed to see if any close connection existed between the composition of the ash and of the soil in which the plant was growing. Swedes were chosen for trial, thus giving a plant grown under similar conditions on widely different soils. In each case two Swedes were taken with a sample of the soil round them; portions representative of the whole root were cut from each, dried, incinerated, and the proportion of lime in the ash determined; at the same time the proportion of lime in the soil was estimated.

LOCALITY.	Soil.	Ash to dry matter.	Lime to dry matter.	Lime to ash.	Lime in soil.	Lime in ash to average.
Weld clay ...	Craneleigh, Surrey	6.69	.42	6.34	.08	47
Sandy loam ...	Cuddington, Notts.	7.51	.72	9.63	.41	72
Loam on millstone-grit ...	Cockle Park, Northumber.	4.33	.45	10.51	.28	78
Light sand ...	March	6.42	.73	11.48	1.43	86
Sandy (recently limed) ...	Westenhanger, Kent	5.29	.65	12.41	.98	93
Clay on chalk ...	Polham, Kent	5.93	.75	12.55	.99	94
Loam on millstone-grit ...	Cockle Park, Northumber.	4.21	.57	13.59	.45	101
Loam on chalk ...	Wye	5.6	.83	14.75	7.32	110
Gault clay ...	Brook, Kent	5.49	.805	14.66	16.71	110
Gault clay ...	Brook, Kent	3.53	.994	28.12	14.11	211
Average				13.4	..	100

Swedes. H. F. Bengel.

In this case, the variations in the composition of the ash are not so marked as before, but a comparison of the proportions of lime in the ash and in the corresponding soils, shows that if anything the ash tells more about the needs of the soil than the requirements of Swedes in general.

But we have only to take a plant like Swedes, whose manurial requirements have been carefully investigated, to prove the fallacy of the ash theory; taking the Rothamsted returns as a basis for calculation, we find that an acre of Swedes will withdraw from the soil about 98 lb. of nitrogen, 33 lb. of phosphoric acid, and 149 lb. of potash. We could supply these substances by a manure composed of 640 lb. of nitrate of soda, 255 lb. of superphosphate, 1240 lb. of kainit.

It is, however, quite certain that the manure for Swedes should be mainly phosphatic, the crop is very often grown with 5 cwt. of superphosphate and 1 cwt. nitrate of soda, i.e., about 70 lb. of phosphoric acid and 18 lb. of nitrogen; or again, with 12 tons of farmyard manure and 4 cwt. or so of superphosphate, which would contain about 130 lb. of nitrogen, 130 lb. of phosphoric acid, and 150 lb. of potash; excess of nitrogen results in a very indifferent Swede, and from most of our soils the crop can obtain its potash without artificial aid.

Garden plants are generally grown in soil already well stocked in the primary constituents of plant-food, so that it becomes more than ever necessary to study the idiosyncrasies of the development of each species by actual experiment, instead of trusting to analyses which lead to fallacious conclusions in the only cases where we possess positive evidence. *A. D. Hall, Wye.*

COLONIAL NOTES.

COFFEE-GROWING IN QUEENSLAND.

I AM sometimes asked, "Will Coffee pay in Queensland?" By this, of course, is meant not whether Coffee is profitable as an article of trade, but whether it, as a field crop, will pay the cultivator. I would advise all those who are in doubt about the matter to visit the State Nursery, and see for themselves the crops on the trees here.

Mr. Dansy, Manager of the Mackay Coffee Co.'s Estate, says he has not seen a better crop in Ceylon. Most people say Coffee must be grown in a scientific manner, and for some this word science seems to have a fearful significance, but at the nursery they may see a crop grown on non-scientific principles [?]. At the outset I planted on scientific lines. Starting at the surface of the ground, it was considered neces-

sequence of this is that the roots cut off in digging receive no benefit, and those at a distance from the holes would have to travel if they wanted to share in the good things supplied in the shape of manure.

My method was to spread the manure over the surface of the ground within a radius of some 3 feet from the stem, and then lightly prick it in with a digging-fork. The result of this was, that as soon as the rain fell, the plants showed dark green foliage in abundance.

It is just possible that when the Coffee-expert visits this nursery he may order all these bushes to be dug up, and I would therefore advise anyone who has been lamenting his ignorance of Coffee-growing, to come here, and after what he has seen, he will, perhaps, have an easier mind.

The other day I had a visit from an intending Coffee-grower, who, no doubt, was impressed with fears for his success, after reading a mass of books

congenial to the growth of the plant, and where the land is exposed to the fury of the gales that sweep over the place, it shows there is not so much mystery about the matter as is supposed. For land such as that at this nursery I believe manuring to be an absolute necessity.

I notice that some trees bear better than others. Some trees are absolutely barren, although I believe I have none here. In Ceylon these trees are called "males," but such nomenclature does not speak well for the botanical knowledge of those who so designate them. The Coffee-tree is not dioecious, it is a hermaphrodite. Perhaps the expression merely means a barren tree; but whatever they may be it would be better to dig them out and plant others in their places. To avoid the risk of raising non-bearing plants, as far as possible seeds should be selected, when it can be done, from the bushes bearing the greatest crop of berries.

The trees here having strong stems and being well-rooted, the branches, as soon as the present crop is gathered, will be thinned out, thus complying with the common sense and scientific instructions as to letting in light and air.

There are many people who, even if they have the necessary capital and knowledge, are physically unfit for the laborious work of Cane-growing, but they would be perfectly capable of growing Coffee. While the price remains at its present figure, Coffee-growing will pay better than Cane-growing at the present price of sugar; and where there is a family of children, the pickers are ready at hand. I feel sure that a good future is in store for the Coffee-growing industry, and it is just those farmers who have 30, 50, or 100 acres of Cane who can go in for Coffee-growing successfully, as they have money coming in to tide them over the three years during which they have to wait for a crop. D. Buchanan.

FIG. 118.—*DAVALLIA FIJIENSIS EFFUSA*.
(As exhibited by Mr. May at the Temple Show)

ary to maintain a clear height of stem of 6 or 8 inches without any branches. The single stem was to be continued, and no suckers were to be allowed to grow.

Under this system I soon found that all the plants would require staking. This was all very well for a few months, but when the branches began to grow, I saw that the stakes were not strong enough, and they had therefore to be replaced; then, when the usual wet season, with its gales of wind swept over the place, neither stakes nor stems could resist their violence, and the greater part of the plants were laid flat. I very soon came to the conclusion that the local conditions rendered this method useless. No more pruning, and no more destruction of suckers took place, the single stem soon thickened, the branches began to rest on the ground and formed the necessary support for the trees. Some books recommend manuring; and the scientific method recommended consists of digging a hole or two round the roots, in which the manure is placed. Now the con-

on the subject. When he had seen several of the bushes, he expressed the opinion that growing Coffee by book was not the way to succeed. There is, however, a danger, of going to extremes on the other side; but it is plain that hard-and-fast rules must give way to circumstances.

Science has done much in the past, and will do much in the future, for agriculture. All I want to impress upon would-be Coffee-growers is, not to let science be the bugbear to frighten you out of the field. If you want to grow Coffee, and you possess average common sense, put that common sense to work. If you have not got a farm, then look out for one—a piece of good land, well sheltered from the wind if possible. Having selected your farm, "look over the hedge" and watch the man who is succeeding in the industry. Take his advice, and follow it, as far as your own particular environments will allow. You are then not likely to fail. If a crop of Coffee-berries can be grown such as may be seen here, where the soil is by no means specially

THE HERBACEOUS BORDER.

HEUCHERA SANGUINEA.

SEVERAL *Heucheras*, with unauthorised names, or at any rate with names not to be found in *Index Kewensis*, are offered this spring in nursery catalogues. Two or three which I bought are already in flower, and seem to be hybrids of *H. sanguinea*. This plant soon showed its readiness to produce hybrids, a casual cross between it and *H. cylindrica* having appeared on one of my borders four or five years ago; its character at once proclaimed its parentage. In hardiness and freedom of flowering it surpasses the seed parent, *H. sanguinea*. A bed of cuttings from it was crowded with flower-stems all through September and October last year, and many buds were killed without flowering. The bed in question is an equilateral triangle, with sides of 4 feet, and contains, perhaps, fifteen plants, each now bearing about thirty flowering-stems, and they will probably continue to be produced till autumn. The original seedling, which has never been transplanted, is about 18 inches square, and has at least 200 flowering-stalks now about to flower, the colour being pink, not without a suspicion of the green tint of its pollen parent. A year or two after this seedling appeared, two others came in different parts of the garden, bearing evidence of being *H. sanguinea* × *H. hispida*; the flowers of these are of a paler red than *H. sanguinea*, the plume larger and more diffuse, and the leaves marked with brown, but less conspicuously than in *H. hispida*. The cross of *H. cylindrica* bears fertile seed, and I have a most curious panful of mongrels now in flower from it. They vary in colour and form, and there are hardly two alike. Whether any will deserve the distinction of being perpetuated I cannot yet say. I think I saved seed, apparently fertile, from the other hybrid also. As for the original *H. sanguinea*, which has been considerably improved by selection since its first appearance here, it flowers abundantly enough here in May and June in warm and sheltered positions, but being Mexican it can hardly be expected to thrive when fully exposed to such weather as we had in March; and in fact where so exposed it is withered past recovery.

It is, however, one of the best importations of recent years, and if taken in hand by skilful hybridisers and made more hardy, and its flowering more lasting, might, I think, become useful for permanent masses of colour to flower all summer. *C. Wolley Dod, Edge Hall, Malpas, May 15.*

THE WORKING VALUE OF FUELS.

IN some experiments carried on at the New York State Veterinary College, it was found that the heat lost by ventilation was 39 per cent. of the whole, and my attention has been called to the fact that these figures, which may be taken as correct, differ seriously from those given in my book on the *Commercial Uses of Coal Gas*, where the amount lost in Messrs. Walker's bottling-stores is given as varying from 22½ to 25 per cent. The explanation is simple, the minimum ventilation required in living rooms is 500 cubic feet of air per hour for each adult; in bottling-stores only a fraction of this is required—in fact, no provision whatever is made for ventilation, and all which takes place occurs from leakage, and the constant opening of doors for the passage of trucks and barrels. The figures given by me are clearly stated as being observed results in practice, in bottling-stores only. I had no opportunity before the book was published of making exact experiments in living rooms, these being very difficult, if not impossible, under ordinary conditions, in any house, the speed of the air currents in the flues varying almost from minute to minute.* Recent experiments in rooms where the ventilation is controlled and can be measured, have established a rule, which may be safely relied on for every practical purpose. The accepted standard is the British thermal unit, i.e., the amount of heat necessary to raise the temperature of 1 lb. of water 1° Fahr., and one unit is required per hour for each degree rise of temperature over the outside for each square foot of glass, or for every 4 square feet of exposed wall, and two-thirds more for the loss of heat by ventilation in ordinary living rooms. The loss of heat in living rooms is an unknown quantity, as it varies in every room, and in the same room from hour to hour; but taking the theoretical value of coal-gas at 660 British thermal units per cubic foot, that of coal 13,000 units per lb., and of coke 10,000 units per lb., it becomes easy to calculate the effective value, and the loss of heat in different systems. A flueless gas stove may be taken as the highest type of efficiency, and using this, 1 cubic foot of gas per hour will be required for every 660 square feet of glass, or every 2680 square feet of exposed wall for every 1° rise of temperature from the outside, and in addition to this, two-thirds of a cubic foot for loss by ventilation. Taking a room 22 feet square, and 10 feet high, with all walls exposed, 2 cubic feet of gas per hour will maintain a rise of 3° over the outside, allowing for the average window surface. The exact figures for warm-air stoves with flues, and for open fires, are not available, and perhaps not possible, but for average practice, it may be taken that nearly one half the total heat is lost in a warm-air stove with a flue, and two-thirds with an open fire. This can hardly be considered as all loss, as the ventilation necessary for comfort and health cannot be always obtained without some assistance, and the so called loss may be partly taken as useful work done. The whole subject is beset with variations and difficulties, and any standard can be proved to be seriously wrong in individual cases, but the figures given may be taken for average work. It must be clearly understood that the figures given are for maintaining the heat, not for raising the temperature of any room quickly, for which a much larger fuel consumption is required.

HEATING PLANT-HOUSES.

These figures work out in practice in greenhouse heating, where steady temperatures are required night and day, and the loss from any system of boilers or stoves can be readily calculated—a matter of interest to nurserymen whose fuel-consumption is a question of vital importance. The loss in most

forms of boilers is enormous, and the subject needs careful consideration. For this purpose, the calculation is exceedingly simple, on the basis of 10,000 units per pound of coke; 1 lb. of coke burnt per hour will give a rise of 10° for every 1000 square feet of glass, or 4000 square feet of exposed wall, not allowing for loss by ventilation. For this, one-half more fuel must be allowed; this gives us the maximum possible duty, and a comparison with the fuel burnt gives the waste. Where the fuel-heat is not utilised there is no doubt that at least 50 to 60 per cent. of the fuel is completely wasted in most of the systems at present in use, and the value of the fuel is not considered as it should be. In my own case, with a Chatsworth boiler, burning gas-coke, and heating a range of houses 45 × 30 feet, one-half of which is kept at a tropical temperature, the flue-heat not being used, the calculated consumption is 8 lb. per hour by theory, allowing one-eighth loss for wind, as the houses are on high ground, and rather exposed (this wind allowance will vary in different districts). The actual winter average is 11¾ lb. per hour, showing a waste of 31½ per cent., nearly one-third of the fuel, this being with a first-class boiler, clean, well set, carefully fired, and of the correct size for its work. It is doubtful if better results could be obtained in practice under any ordinary conditions.

The following rule may be taken as a guide for coke-fired greenhouse boilers:—

For every 1000 square feet of glass, and for every 4000 square feet of exposed wall, for each 10° rise of temperature over the outside:—Loss through glass and walls, 16 oz. per hour; loss by ventilation, 8 oz. do.; loss by wind (average), 3 oz. do.; loss by boiler and flue, 13 oz. do.: total, 2½ lb. Three-fourths of the flue-loss can be recovered by taking these under the beds in the houses.

Any fuel consumption over this may be taken as waste, which can be prevented. *Thomas Fletcher, F.C.S.*

THE ROSARY.

THE ROSE GARDEN IN MAY.

THIS ought to be a busy month with Rose-growers, and very much of the future success of the Rose-garden depends upon the care and attention bestowed upon it now. There are of course Rose-gardens and Rose-gardens: there is the Rose-garden of the exhibitor in which the chief object is to obtain large and well-developed blooms for the exhibition-table, in this class everything depends upon the certainty of obtaining fine blooms; there is the Rose-garden of the suburban amateur, whose ideas of beauty mainly consist of rows of standards with mop-like heads. There is the Rose-garden of a man whose ideas are mainly æsthetic, who has ample space, and a good supply of the needful at his disposal; he talks about beds of Mrs. John Laing, General Jacqueminot, or Catherine Mermet; he is great upon hedges of Crimson Rambler, and an arcade of Roses trained over a path so as to form arches. There is the Rose-garden of what I may term the botanical Rose-grower, who despises the fat Roses, as he calls them, of the exhibitor, and whose special love is given to the single Rose of the various countries; he loves an Austrian yellow or copper, and to him a Bardon Job or Carmine Pillar is all that can be desired. Of course to many of these persons who allow their Roses to gang by themselves, the month of May brings no peculiar obligations, and it will be useless and tiresome to give a multiplicity of directions, and I therefore rather confine myself to those who, like myself, enjoy the beauties of a good, well-developed Rose, although I never place it on the exhibition-table.

Enemies of the Rose.—Roses, like all beauties, have their host of admirers; but they also have their enemies, and it is of the latter we have at this time to think the most. There is, first of all, that little pest which Shakespeare has with his usual keenness with regard to nature said of Viola in *Twelfth Night*, "she never told her love, but let concealment like a worm in the bud feed on her damask cheek." As the shoots begin to grow and the flower-buds to develop,

this pernicious beast makes its appearance. It mostly lays hold of the leaf, which the little maggot attaches to one of the buds, and quietly gnaws away at it; it is thus somewhat shrouded from view, and the casual observer might think there was nothing the matter. But the rosarian knows better, and is therefore ever on the watch, for even if it gets as far as this attaching the leaf to the bud, the beauty of the bloom is destroyed. Fortunately, before it does this, it shows itself in the leaf, and whenever one sees the leaves at the top of the shoot looking rather confused, he may be sure the enemy is there; to get rid of him is, of course, the primary object, and this can only be done by the unpleasant process of hand-picking and destroying them, and therefore it is well to employ some little fingers to go over the shoots every day for some time. I prefer the little fingers should be those of a girl, as boys are rougher and more likely not only to destroy the maggot but to injure the shoot; no insecticide seems to be of any use, and I have never found that the maggot is any the worse for its application. Mildew is another pest of a different character; it is not so hurtful to the tree, but very disfiguring, and as all rosarians know, there are some varieties which are more seriously affected by it than others. Jean Libaut and Her Majesty are amongst these; whilst there are others, like Mrs. Paul and Mrs. W. J. Grant, which are nearly mildew-proof, and it is somewhat curious that Tea-Roses seem to be so little affected by it. I believe it is generally looked upon as being favored by alternations in temperature, and one would have thought that the more delicate Tea-Rose would have been more affected by it; but it is not so. Syringing with a solution of soft-soap or dusting with sulphur may be applied, but these are all disfiguring, and the rosarian would be glad if he were spared the necessity of using them. Aphis or green-fly is one of the most persistent or troublesome enemies of the Rose, and is in some seasons very abundant; some localities seem to suffer more from it than others, and it is curious to notice that when rosarians meet together how varied are their experiences as to the pest. Sometimes the young shoots are literally covered with them, and there is great difficulty in getting rid of them. Where the collection is small, a Rose-grower will not object to employ some one to pass the finger and thumb up each shoot, and afterwards syringing the plants with clear water. Where it is large this is impossible, and syringing with a solution of Gishurst compound, and afterwards with clear water, will get rid of them. Perhaps in no point is the difference between an exhibitor and a non-exhibitor so manifest at this season as in the question of mulching; the former will now probably cover his beds with a good coating of farm-yard manure, which does not add to the appearance of the Rose-garden nor to the pleasure of those who go amongst the Roses, but which the exhibitor considers necessary for the full development of his flowers. Not being an exhibitor, my plan is at this season to gently fork over the beds, and leave them all neat and trim; it certainly adds to one's pleasure in going amongst them. But if I do not mulch, I do apply liquid-manure; this should be done before the buds begin to develop, and I generally do it twice or three times, allowing the space of several days between the applications. It should be applied in a clear state, if possible, and some soot should be placed in the vessel that contains it.

Seasonable Hints.—As the shoots begin to develop it will be necessary where they are strong to prevent them from being blown about, and so a neat stake ought to be placed, to which they should be loosely tied; more especially is this needed with newly-budded Roses, for they are very apt to be nipped off with the high wind, and sometimes even the shoots are blown out at the point of junction.

In these observations I have made reference merely, as I have said, to the two great classes which form the bulk of the Roses in our gardens, the Hybrid Perpetuals and Teas. Of course, climbing Roses and Roses on walls have to be treated differently, no one would dream for instance of treating Lord Penzance's

Hybrid Sweetbriars, or the rampant-growing Polyanthus, such as Crimson Rambler, in the same way. As the young shoots are developed they must be tied in, as on these will depend the bloom for the next season; and when the flowering season is over the old flowering-wood of this year will have to be cut away, so as to allow space for these young shoots to grow at will, and get the full benefit of air and sunshine during the summer months. I have heard people complain of Crimson Rambler not flowering, but I believe it is attributable to this cause, that the shoots have been pruned and the old shoots left in—a fatal mistake. Ag. in, all rampant-growing Noisettes, or those which are called Dijon Teas, should be treated in the same way; they require but little cutting back, and a great deal of cutting out. Such kinds as Rêve d'Or and Borquet d'Or are especially valuable, the former may be called Tea Noisette, and the latter Dijon Tea; they are both nearly evergreen, and are clothed from the base to the extreme end of the shoots with bright green foliage; while Gloire de Dijon, Madame Lerard, and others, have long bare shoots, which do not enhance their beauty. Some of Lord Penzance's Liriodendrons make capital plants when budded on tall standards, and allowed to droop, but it is best to leave these alone, too, so as to let them grow in a more natural state. Those of us who have walls are now beginning to rejoice in the first fruits of the Rose season. I have already had blooms of Climbing Devonians and Longworth Rambler, and I see that the buds of Fortune's Yellow are rapidly advancing; but as we are getting our usual "cold wave" in the third week in May, it is possible that for a little while there will not be much progress, and we shall have patiently to wait for the rosy month of June.

Wild Rose.

KEW.

THE ROCKERY.—At the present time, this, one of the prettiest parts of the gardens, and the one having a permanent interest for all those who love alpine and early flowers in beds or borders, or in their proper place—the rockery, is well worth a visit. Varieties of *Aubrietia deltoidea* are prominent objects by reason of their forming distinct masses of colour; and we noticed *A. d. Andersoni*, purple; *A. d. violacea*, reddish-purple; *A. d. W. Ingram*, bright lilac; *A. d. Hendersoni*, deep purplish-blue—one of the best; and *A. d. Dr. Mulus*, bright blue—very pretty; *Heuchera pubescens*, and *H. humulus*, species having a darkly-zoned leaf; *Epimedium rubrum*, with green, brown-edged leaves, are useful as affording pretty leaf-contrasts at this season, as is also *Rodgersia podophylla*, the colour of whose palmate leaves is of a greenish-bronze; and the height of the plant about 2 feet. *Meconopsis Wallichii*, planted out in a recess two years ago, has also foliage of a rare colour, and the plants are doing well in the peat-bed along with hardy *Cypripedium* and various *Primulas*. Whilst writing of these hardy foliage-plants, mention should be made of *Saxifraga sancta*, a plant that makes pleasing green cushions; of *Thymus Serpyllum* and *T. s. lanatum*, both capital dwarf, creeping species for covering bare rocks, provided their roots have access to porous soil of a foot in depth; of *Acena microphylla*, a dwarf creeper from New Zealand, of rapid growth, the minute leaves forming a brownish-green mass. The flowering plants consisted of *Trillium grandiflorum*, *Veronica teucrium*, with an abundant show of flower-spikes; *Gladiolus anaticus*, 1½ foot high, with reddish-purple flowers; *Iberis sempervirens Garrexianna*, forming great pendent masses of flowers; *Rhododendron indicum* anicum, with reddish-purple flowers; *Armeria cæspitosa*, forming cushion pink flowers and rosettes of green leaves; *Anthyllis montana*, a spreading, dwarf-growing species; *Noceæa alpina*, a plant of very low growth, covered with white flowers; *Pentstemon confertus*, *Geum montanum*, a pretty yellow-flowered plant, 6 inches in height; the elegant *Euphorbia myrsinites*, of the same height; *Phlox anæna*, *P. divaricata*, *P. reptans*, and others; *Chrysanthemum caucasicum*, a plant 9 inches high, with white flowers, having a yellow disc; *Tulipa australis*, a yellow-flowered

species; *Linum arboreum*, with yellow flowers freely produced, the total height of the plant being 1½ foot; *Dianthus plumarius*, "feather Pink," and *D. cæsius*, giving great promise of bloom; and *Potentilla splendens*, a dwarf plant, with white flowers.

The aspects of the rockery are constantly changing, so great is the number of the plants grown thereon, and visitors who may chance to find any of the plants named have ceased to flower, are certain of meeting with others equally beautiful.

"LA MAISON RUSTIQUE."

(Continued from p. 276.)

THE chapters devoted to the "Garden of Pleasure, or Flower-garden," are very interesting. Unfortunately, this part of the work is so badly translated, that the English reader is often left with an impression quite different from that which the author wished to convey. The opening paragraph is almost eloquent, and reminds one of the charming and well-known chapter of William Lawson "On Ornaments":—"To heare the ravishing musick of an infinite number of prettie little birdes, which continually day and night doe chatter and chant their proper and naturall branch-songs upon the hedges and trees of the garden, and to smell so sweet a nosegaie (boquet = scent) so neare at hand; seeing that this, so fragrant a smell, cannot but refresh the Lord of the farme exceedingly when going out of his bed-chamber in the morning after the sunne rise, and whiles as yet the cleere and pearle-like dew doth pearch upon the grasse, he giveth himself to heare the melodious musick of the bees, which, busying themselves in gathering of the same, do also fill the air with a most acceptable, sweet and pleasant harmonie."

Like the kitchen garden this is also to be "compassed in with arbours," which in this case were "made of Jessamin, Rosemarie, Boxe, Juniper, Cypress-tree, Savin, Cedars, Rose-trees, and other dainties," trained over poles of Willow and Juniper. The alleys were to be of beaten sand, of marble, or of slate-dust, and the walks to be paved with stones, tiles, or with "faire stones such as staires are made of."

This garden (parterre) was divided by a 6-foot walk into two equal parts, "The one to contain the herbes and flowers to make nosegaies and garlands of ('bosquets, chapeaux et couronnes'), and was called the 'Nosegaie Garden.' The other division to contain all sweet-smelling herbes used for garlands, &c., but of which the whole herb and not the flowers only were used." The former were planted in beds and borders like those in the kitchen garden. Of the latter some were planted in the same manner, some were "set upon seats," some in mazes, and others in compartments formed of interlaced beds. The latter are the old English knots, and will be referred to further on.

The following are some of the flowering plants:—March Violets, or the common *Viola odorata*, of which the single and double were grown. In order that the scent may be preserved, it is noted that the flowers must be gathered before sunrise, and when it "raineth not." "White, yellow, and red Gilliflowers doe Crave, the like ordering that March Violets doth." "The white is *Matthiola incana*, the yellow *Cheiranthus Cheiri*, and the red I have not yet determined. In the French edition these are respectively "Giroflées blanches, jaunes et rouges." Daisies are mentioned, then the purple velvet flower (*Passe velours*), "called in Latin, *Amaranthus*." This is the old flower, Gentle, or *Celosia*. The *Amaranthus* of "Lycidas" is *A. tricolor*. The least frost caused its richly-marked leaves to fall. Hence the aptness of Milton's "Bid *Amaranthus* all his beauty shed." Love-lies-a-bleeding may be Spencer's

"Sad *Amaranthus*, in whose purple gore
Meseemes I see *Aminta's* wretched fate."

Each of these have been designated the flower Gentle, or *Passe velours*.

Then we come to Gilliflowers—*Œillets* of all kinds, of which there are five species in Latin called "*Vettonica atilis* ou *Ocellus Caryophyllus*." The first is an old name for the cultivated or double (*Altis*) Carnation, but our author has somehow got confused concerning the number of species. He says the largest and finest sorts were cultivated in Provence, thence called "*Œillets de Provence*." Others less carefully treated were called "*Œillets des Rosettes*," which Surfleet transmutes into "Purple Gilliflowers." Both designations represent sorts with double flowers of varying colours.

Following these we have Indian Gilliflowers (*L'Œillet d'Inde* ou de Turquie, appelé des Latines *Petilius Flos* ou *Ocellus Indicus* et des Italiens *Belveder*). The identity of this flower is fully established by Dodoens. It forms another curious instance of one flower usurping the name of another, *Petilius Flos* being that of an unknown plant described by Pliny which had flowers very like the French Marigold, only the latter had reddish-yellow flowers, and the blooms of the former were coloured like the Sweet Briar. *La Maison Rustique* describes the French Marigold. *Belvidere* was quite another plant—one of the *Campanulas*, and later *Chenopodium Scoparia*. Then we have "Wild Gilliflowers, as well white as red," which are respectively *Lychnis vespertina* and *L. dioica*, in French "*Œillets sauvage*;" "double and single forms of both were grown. Of "Lillies" = *Lys*, "tant blanc que orange," were the only two kinds known; they are, of course, *Lilium candidum* and *L. umbellatum* or *bulbiferum*. They flowered in the month of June.

Methods of changing the colours of the flowers and of having them in bloom at any season are stated, but like much that is said in addition to that, these methods are of no value. "Small Paunces" are *Pensée menu*, or autumn *Violets*, or *Viola tricolor*. Other flowers include *Daffodils*, *Anemones*, *Hyacinths*, *Pæony*, male and female (*Pæonia officinalis*), "Hollechocks" for *Guimauve*, *Orpin* (*Sedum Telephium*), *Palma Christ* (*Ricinus*), and many more.

A few species of *Roses* are named, but they call for no particular mention, save that a "dammaske of the colour of scarlet, which we call *Provence Roses*," should read "*Damask Roses*, and '*escarlataines*,' which we call *Provence*."

"Of sweet-smelling Herbes" there is a chapter. These were grown for garlands for the head, and were mostly well-known aromatic herbs. They are treated somewhat in this way:—"Basill, if sown in a dry spot will become either wild tyme or cresses." "It must be watered at noontide, and if sown with curses and injuries offered to it," the plant will thrive better. Cumin, like Basil, "must be curst and railed upon." "Bishopsweed" appears in this chapter. This, however, is not the ineradicable weed of that name, but *Amni majus*, one of the most decorative of the *Umbelliferae*, with pure white flowers. It was also called *Bulwort*, *Herb William*, *Cumin Royal*, &c., and was held in great repute as a cattle medicine. *Penny Royal* (*Pouliot*) was also much esteemed. It was known in England as *Pudding-grass*, and in *Cheape and Goode Husbandrie* it is "*Poullioli roiall*." The name is a corruption of "*Pulegium* (*Puleium*) *regale*," which became by an easy transition "*pouliot*" or "*poullioli royal*," and thereafter the meaningless *Penny Royal*. "*Pouliot Sauvage*" is the "*Catmint*" which Mr. Henslow could not determine. It was called *Pulegium silvestre* and is *Calamintha officinalis*, *Nepeta*. Miller's Dictionary gives one of its names as "*Catmint*." The plant smells something like the *Pennyroyal*, hence no doubt the reason for a "common" and a "*rozall*" *Pulegium*.

Another interesting plant is the "*Pomme d'Amour* (which the Latins call *Mala insana*) by reason of the beauty of the fruit." I can only give a sample of the naughty things said of it by our translator. "It engendreth cholerick humours, headach, sadness, melancholic dreames, and in the end long continuing agues." Hard words, and these not the worst, to be published of the Tomato! The true Mad Apple or *Mala insana* was however the Egg-Apple, *Solanum oviger*.

A long chapter is devoted to that portion of the flower garden which was cut up into various shaped beds, and which were called by the names of *Compartment* border, broken border, and *Parterre*. The "*Compartment*" was a small bed, generally square, intricately and geometrically subdivided, and was the simple knot of English gardens. The "*Compartment*" appears to have been commonly surrounded by a border, which was sometimes subdivided into little beds, and sometimes broken up into small beds with bare spaces between. These were also called knots in England, but in the French edition of this work are named "*A Compartment with borders*," or a "*Parterre*." Sometimes the whole of the ground was broken up into beds of a simple design, and this was a "*parterre of broken beds*." "Borders" also referred to the space of ground running alongside the walks and to the beds between the "alleys." Surfleet's translation is so badly done in this chapter that one can form no idea of the meaning without consulting the original, consequently, most of these notes are derived directly therefrom. In all the geometrical designs there is a double set of lines, which formed very narrow alleys,

the edges of which were preferably planted with Lavender or Rosemary. Box is condemned on account of its smell. The portions enclosed by these were planted with Pennyroyal, Wild Thyme, Sage, Hyssop, &c., and all were kept closely cut. Sometimes, instead of a geometrical design, a flower de luce, a true lover's knot, a lion rampant, a bird or even a man would be portrayed, these, in every case, being marked out by lines of Rosemary. The surrounding borders were commonly filled with the same plants as the central compartment or knot. Occasionally a dwarf shrub was set in each corner, but care was always taken that there should be an unobstructed view of the whole parterre. Not infrequently two species of plants only were used, as, for example, Lavender for an edging and Pennyroyal for a carpet. When the borders surrounding the central compartment were not continuous, but broken into small isolated beds, a greater variety of plants were employed, and included Violets, Daisies, Camomile, Marjoram, &c., as Surfleet says, "to give grace to the quarters," but as the original puts it, "to give colour to the little beds." A pretty design portrayed in *La Maison Rustique*, and designated a "Border with simple compartments," will be found in *A History of Gardening in England*, from *The Gardeners' Labyrinth*. In this example the space between the parallel lines consists of narrow alleys edged with Rosemary or Lavender, the interspaces being filled in with Pennyroyal or Thyme. A number of knots copied from Markham's *Countrie Farm*, as well as the whole of Lawson's designs from *The Countrie Housewife's Garden*, are given in *The Formal Garden in England*, a work brimful of information.

The labyrinth of *La Maison Rustique* was simply a flat design laid out with Lavender or Rosemary as divisions to the walks, which were planted with Camomile, and to supply which, as we have already seen, a space of ground was set apart in the kitchen garden. Labyrinths for a long time were very popular in England, and from a design of Lawson's they are shown to be free from sameness.

I may only shortly add that the ground devoted to the cultivation of "Taxell," Woad, Saffron, &c., as well as the orchard of "Greene Plot," lay close to the gardens just discussed, and all were in close proximity to the dwelling-house. R. P. Brotherston.

(To be continued.)

AMERICAN NOTES.

FROST DAMAGE.

THERE is always a scare in the fruit-growing districts, especially in the "Peach-belt," every spring over the frost-damage to the fruit-buds. We have all grown to expect such talk at this season, and it is usually considerably discounted. It seems probable, however, from reports now obtainable, that the damage this spring has been more general, and on that account quantitatively more than usual. Damaging frosts are reported from California, disastrous freezes from Texas, Oklahoma, and Kansas, and severe cold with snow in Maryland and Delaware. The truck-growers are said to have suffered considerably from biting frosts as far south as Norfolk, Virginia, and North Carolina. It is, however, still too early to predict a certain shortage in any of the staple fruit-crops.

SAN JOSÉ SCALE SCARE.

The talk about the San José scale in this country seems to be diminishing in its flow, and is growing distinctly cooler. On many hands there is a resolute dissent from much of the florid statement which has been most conspicuous for some time past, and conservative expression is generally giving place to the excited talk of a few months ago. There certainly never was any justification for a great deal of the alarm which people felt, and still less for the alarm talk which others talked. For a time it was assumed to be possible and feasible to destroy the scale entirely from eastern orchards and nurseries. But as every experiment in this direction was necessarily a striking failure, the experimenters, who have assumed the necessity of total annihilation, were constantly increasing the feeling of alarm by their negative results. Another very respectable number of horticulturists, nurserymen, fruit-growers, and entomologists felt that extensive and drastic legislation, establishing state, provincial, or inter-state inspections, was very im-

portant, and a great deal of the highly-coloured talk which we have heard was merely the argumentative wash, which is always necessary in getting bills through a Legislature. But now that a few of our best known authorities have taken the stand that neither complete extermination nor legislature restriction is the best means of combating the scale, we find ourselves following a more hopeful lead. Legislature is still felt by many to be important, or even requisite, and some, of course, have not changed the views which they originally formed; but we all breathe easier when we are told that the practical control of the insect has been fully demonstrated—that while it cannot be exterminated, it can be satisfactorily suppressed by feasible means. There can be no doubt that public opinion is fast settling down to a milder view of the situation, and that, for the most part, nurserymen and orchardists, who were measurably frightened, are now taking heart once more.

The Pruning Book is Professor Bailey's latest venture in the literary line. This volume forms another of the Garden-craft series being published by the Macmillan Company. This is probably the first work of any pretensions which has been devoted entirely to this subject, and yet the amount of interest in the theory and practice of pruning would certainly warrant such a book. There have been many good paragraphs and short treatises written on the subject of pruning, as we all remember. Du Breuil, Poiteau, Sachs, Sorauer, Lindley, Koopman, and Barry, with others, have had things worth saying. Professor Bailey has availed himself of their work; but has combined and edited it in his usual felicitous manner, and has added other material which is at least as good as new. Still, the book, as a whole, like others of his recent works, shows the effect of insufficient condensation. Professor Bailey has the best intellectual digestive apparatus in the country for working over old material, and making something new and nourishing out of it; but *The Pruning Book* shows evidences of hyper-digestion. P. A. Waugh.

THE WEEK'S WORK

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

The Latest Peach-house.—The final thinning may now take place—that is, before the stone hardens, leaving a few extra fruits in view of eventualities. It is difficult to say of any particular tree what is over-cropping, as some trees will carry 400 fruits, whilst another may be over-cropped with half the number; and in leaving a crop to ripen, the health and vigour of the tree must receive attention, the stronger the greater crop. Never leave a middling crop, if it can be helped, on a robust-growing tree, or the latter will run too much wood, and it may prove unfruitful until replanted. Naturally large-fruited Peaches and Nectarines require that rather fewer be left on a tree than would be necessary with a variety whose fruit is small or middling in size. For the latter 1 foot superficial is a fair crop; and a little more for the largest fruiting varieties. Nectarines may be thinned of their surplusage in a manner similar to middling or small-sized Peaches. In order to avoid crowding the shoots, give regular attention to the removal of such as are superfluous, and of old and weak fruitless wood. Shoots when they have reached the limits allotted them, must be stopped by having the point nipped out; and laterals, or secondary shoots, nipped in front of the third joint or leaf. The securing of the shoots to the trellis should go on simultaneously with their thinning and regulating. When Peaches are wanted as late as possible, the trees may be retarded by the freest ventilation whenever it is safe to afford air. Red-spider will be apt to infest the trees, but it can be kept in check by heavy daily syringings. Aphides and thrips may be destroyed by fumigation with Tobacco, or vaporisation with the XL-All liquid. Mildew is troublesome in some peacheries, attacking both fruit and foliage. The sulphide of potassium remedy should be applied (frequently given in these pages), and the worst affected leaves cut off and burned. Fruits once affected by mildew cease to grow, and they should be removed likewise. Some gardeners use flowers-of-sulphur against mildew, mixing half a pound of sulphur into a thick paste and adding it to 2 gallons of water, using this with a syringe, and omitting the ordinary daily syringing with clean water for a few days.

Melons.—The plants may be set out on hillocks, hot-bed frames or hot-water pits with every prospect of obtaining good crops. Hot-beds in pits, or frames that have been used for propagating or for Potatoes and other vegetables, if freshened up with stable dung and tree-leaves, may be used for them, but new hot-beds are best. Let the pits and frames be well washed, and white-washed, first using a wash of petroleum in soap-suds, at the rate of a quart per pint of the former to one gallon of the latter, and sulphur may be ignited in the pits, &c. A Melon bed should consist of not less than 6 inches of heavy loam that has been a year in stack, and this should be raised to 1 foot in the spot where the plants are set out. This will render the fatal malady of stem canker rarer. Let the soil be made very firm by ramming or trampling it. No Melon-plant should be set out that is weak or insect-infested, and to make sure that no insects are present lay the plants on pots on their sides on a mat, and gently syringe the leaves with warm water. Melons may stand single 2 feet apart, or two plants may be put out under each light on one hillock, that is at 3 to 4 feet apart. Let the stems be sunk in the soil to a point nearly up to the seed-leaves, and afford warm water to settle the soil. When the roots have taken to the soil pinch out the point. When the day is likely to be fine afford a small quantity of air early in the morning, increasing it as the day advances, but taking it off if clouds obstruct the sun's rays. In fact, constant watchfulness is required at this season. When no hot-water pipes exist, early closing of the lights, say by 2 P.M., is necessary during early summer, damping the soil only on dull afternoons, but affording a copious syringing if the day is warm and bright, which must be discontinued for a time when the plants flower. Melons on hot beds do not require water very often, and it should only be afforded when the soil is getting dry, and the soil should be on the side of dryness at flowering time.

HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

The Destruction of Insects on Trees and Bushes.—The chief part of the work of the fruit grower at this season is the application of means to lessen the number of his insect foes. Aphides increase enormously fast on the Peach and Plum trees, the foliage being very soon seriously injured by their causing punctures that result in disfigurement, from which there is no recovery, and the crippling of the young shoots. Immediate steps should be taken against them, the lice being much harder to kill when they attain their full size and the leaves curl up. A safe remedy for aphides is a solution of soft-soap at the rate of 4 oz. to 1 gallon of rain-water, and it is a more effectual one if half-a-pint of strong tobacco-water be put to every 3 gallons of the soap-suds. Insecticides should be applied to the trees late in the afternoon. If an insecticide is used of which the gardener is ignorant, the trees should be syringed with clean water within one hour of its application. Compared with the cultivator of fruits under glass, the hardy fruit-man is unfavourably placed in regard to the foes that beset him on every hand, and constant watchfulness is called for if they are to be kept in check. Insect-infested trees give poor returns in fruit; moreover, the wood for next season's crop is weakened. Some gardens are provided with a system of underground water-pipes, and it is then an easy matter with the hose to keep trees and bushes free from many of the gardener's plagues by syringing them on alternate afternoons. The water should be directed to the underside of the leaves mostly. Cherries are liable to infestation by a black aphid, difficult to kill, and rapid of increase. In the case of this fruit, some of the worst leaves may be picked off, but care must be taken of all shoots required for furnishing the tree, and the trees should be syringed regularly with soft soap-suds until they are cleared of aphid. Weak trees are more liable to attacks of aphid than vigorous ones, and the use of some phosphatic manure is of great assistance to such in overcoming the effects of a bad attack of this pest. A suitable mixture consists of two-sixths superphosphate of lime, two-sixths steamed bone-meal, one-sixth kainit, and one-sixth nitrate of soda, and from 4 to 6 lb. per tree may be evenly spread over the soil and lightly forked in; and if the weather be hot and dry, a light manurial mulch may be put over all and weak liquid-manure applied occasionally.

Peaches.—In the colder parts of the country, nets, blinds, &c., should remain in use till warm weather sets in, but they must be drawn up by day, or great tenderness of the shoots and leaves will arise.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking

Dendrobium Phalaenopsis, and Others.—This species is one of the most valuable additions to this popular genus during late years, and is very useful for furnishing flowers for cutting. The plants have commenced to grow, and will therefore need immediate attention, as repotting should be done before the young growths have made much progress, or have emitted roots. Those plants not in need of repotting, may be relieved of the old material from between the roots, and fresh compost afforded. Any that do need increase of rooting-space must be transferred with the least root-disturbance possible. The plants will thrive in pots, teakwood-baskets, or shallow pans, and it is important that they should be small in proportion to the size of the plants. My experience has led me to prefer small, shallow pans, with perforated holes around their sides. Copper-ware handles are fastened to the pans, and they are thus suspended to the roof, the apex of the old bulbs being a foot below the glass. Give ample drainage, and cover this with a thin layer of fibrous-peat and sphagnum-moss. It is advisable to include a few brick pieces of crock with the soil, and to pack the compost firmly around the plant. Place the plants in the hottest and lightest position available. Until the new roots obtain a firm hold of the soil very little water will be required. A very thin shading will be necessary, and thus only during the very hottest part of the day. While the plants are exposed to full sunshine, and as the inside temperature increases, ventilation should be gradually increased; but if shading becomes necessary, the amount of air must be slightly reduced. Soon after 2 P.M. the shading should be removed, and for about half-an-hour allow plenty of air to again circulate freely around them. Then as the sun shines full on the plants close the ventilators, and well damp the floors, staging, &c., and syringe the plants overhead with tepid rain water. The temperature of the house may quickly rise to 100° or more. Other species of *Dendrobium* which thrive under similar treatment are *D. superbiens*, *D. Goldiei*, *D. bigibbum*, *D. lineare*, *D. strebloteras*, *D. stratiotes*, *D. secundum*, *D. taurinum*, and *D. Bensoniæ*; also such species as *D. macrophyllum*, *Vitchianum*, *D. Johnsoniæ*, *D. revolutum*, *D. undulatum*, *D. Hughii*, *D. Treacherianum*, *D. O'Brienianum*, and *D. atro-violaceum*. The new *D. spectabile* will succeed in the same temperatures, but requires to be moderately shaded from the sun. The tall growing *D. Dalhousieanum*, *D. fimbriatum*, *D. f. oculatum*, *D. moschatum*, *D. dioxanthum*, *D. calceolus*, *D. clavatum*, &c. that emit roots when the new growths are a few inches high may require fresh material to root in. An excellent place for these species is on the centre stage of the East Indian-house or plant-stove.

Phaius tuberosus.—In a hot moist shady corner of the East Indian-house the remarkable *Phaius tuberosus* should be grown. It is necessary to thoroughly examine each growth of this plant as often as possible, sparing no pains to get rid of the small yellow thrips on their first appearance. If the growths be kept perfectly free from these insects, no difficulty need be experienced in obtaining good flowering plants. *P. tuberosus* being a scandent grower, requires plenty of room for the extension of its creeping rhizomes, and for its long fleshy roots to spread freely in all directions. Rather long shallow pans are best, and they should be filled to two-thirds of their depth with broken crocks and charcoal. Place a layer of sphagnum-moss over the drainage, then a layer of peat; next lay the rhizomes upon this compost, then fill closely up to the stems with living sphagnum moss. After repotting, afford just enough water to induce the moss to grow, gradually increasing the quantity as the leaves unfold, and the roots are seen pushing about in the compost.

Vanda Sanderiana and heat-loving *Cypripediums*.—Plants of *Vanda Sanderiana* that are now rooting freely are seldom over-watered at this season; those that are on blocks or teak-rafts require to have their roots moistened at least twice a day. In the East Indian-house the whole of the *Cypripediums*, if properly potted, should have a thorough watering two or three times a week. Prevent water lodging in the growths of such species as *C. Stonei*, *C. Lowii*, *C. lævigatum*, *C. philippinense*, *C. glanduliferum* (*acrostans*), &c. as they are liable to decay from this cause.

Lycastes, such as *L. Skinneri*, *L. plana*, *L. aromatica*, *L. candida*, *L. cruenta*, *L. Deppei*, *L. gigantea*,

L. fulvescens, and *L. lanipes*, may at once be repotted into equal parts of rough fibrous-loam, peat and sphagnum-moss. *Lycastes* may be grown at the warmest end of the cool-house, and be kept well shaded from all sunshine, even a strong light without actual sunshine will sometimes cause the young leaves to assume a sickly hue. Although moisture-loving plants, they require as much care in watering as the deciduous *Calanthes* in the early stages of growth.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Carnations.—These plants are rapidly pushing up their flowering stems, and, if time permit, a neat painted deal, or Hazel-stake, should be placed to each stem, and secured to it with fixed bands of matting. Such of the plants as may be expressly grown for furnishing flowers for cutting may have one stake only with two or more embracing bands of matting supporting the whole of the stems. This admits of the removal of the flowers without severing the fastening. If extra large flowers are required, disbudding should be resorted to, and one bud only be left on each stem. It is a wasteful method, and has little to recommend it beyond giving size; although it is always advisable to practice modified disbudding, which consists in removing the uppermost side-buds that are in proximity to the central bloom-bud. The beds should be hoed to keep them free from weeds and to aerate the soil; and when hot weather ensues, a mulching of spent Mushroom bedding or cocoanut-fibre should be spread all over the ground.

The Rose Garden.—The growth of the plants is robust, and in our garden there is every prospect of good flowers later on. The Rose-maggot abounds, and hand-picking has to be persistently carried out, or much injury would occur to the Roses. The Rose-aphis is not as yet present in any great numbers; still, precautionary measures should be taken, and the plants syringed with tobacco or quassia-water or soap-suds, or be dusted with powdered tobacco, the last-named being syringed off the plants the following day. Let tying and nailing as the case demands be attended to as the shoots lengthen, doing nothing, however, stiffly. The same remarks hold good for Rose bushes that have their shoots fastened horizontally over the beds with pieces of wire or stout hooked pegs of wood. Felleberg Noisette, Tea Roses of rampant growth, Gloire de Dijon, Gloire de Rosamene, Madame Desprez, W. Allen Richardson, Crimson Rambler, and many old varieties of Roses are excellent for this kind of training over the soil.

General Remarks.—The recent rains which have been generally followed by an increase in the temperature, have induced more rapid growth in most garden plants, and many of these will now need attention in the matter of staking and tying. Weeds are likewise growing fast and must be destroyed, therefore let the hoes be kept going on beds and borders. Mowing will take up a good deal of labour, but it must not be neglected or the quality of the turf will soon show deterioration. After every mowing let the edges of the mown part be trimmed with the shears. Hedges of Box, Sweet Briar, Rosemary, Thuya, and *Pyrus japonica*, if it be gone out of flower, should be clipped without delay, and all paths made of pit gravel, rolled after rain, in order to keep a smooth surface.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Chrysanthemums.—Plants, whether intended for the production of large blooms, or to be used for decoration, should now be in a suitable condition for the final potting. Prepare, therefore, all materials that will be required for the work, so that no delay occurs when potting has commenced. For a potting-compost use good turfy loam, with a liberal sprinkling of bone-meal and finely-sifted wood-ashes. Should the loam be rather heavy, a small quantity of sand may be added. Let the whole be thoroughly mixed, and afterwards protect it from rain. Old flower-pots should be thoroughly cleansed, and new ones will require to be well soaked in water. They may then be sorted into sizes, and the crocks placed in them, an operation that should be given every care. Select the desired number of plants, and grade them according to the size of flower-pots they will need. The surplus plants may be planted out, the large-flowering varieties for stock, and the decorative

varieties for potting-up in September. To provide security from winds whilst the plants are out-of-doors, stout posts should be driven firmly into the ground, and a couple of lines of thick wire stretched between them, whereon thin laths or Bamboo-rods may be tied to train up the growths of such plants as are intended to give large blooms. The points of such plants should now be pinched-out if a natural break has not already occurred. Stand the plants on boards to prevent the roots getting into the soil. Bush-plants may be plunged in coal ashes, placing a piece of slate underneath each pot. Keep a sharp look-out for green-fly, dusting the plants with tobacco-powder if in the least degree they are attacked by this pest. Pot firmly, and afford no water for two or three days if the plants were in a moist condition when potted. Syringe them over-head two or three times a day if the weather be fine.

Clerodendron Balfouriana.—Young plants in 4-inch pots, if growing freely, may be given a shift into others 2 inches larger. Train the shoots near to the glass, and fully expose them to the sun. This plant is useful for decoration if grown in bush form, or as a small standard. If intended for bushes, the shoots should be pinched when about 6 inches high, and the operation should be repeated several times during the season. Those for dwarf standards may be allowed to attain a height of 1 foot or more, as may be desired, before they are pinched.

Begonias.—The early-struck cuttings of the winter-flowering varieties will now require a shift into larger pots, using a light, rich soil. Place the pots on a cool bottom in a moderately-warm pit, and shade from the sun. Water with especial care until the plants are growing freely. Cuttings may now be inserted of the later-flowering varieties.

THE KITCHEN GARDEN.

By J. W. MCHATTIE, Gardener, Strathfieldsaye, Hants.

Peas.—Another sowing of Marrowfat Peas should be made, sowing thinly in broad, flat drills; and mould-up such Peas as are above-ground, at the same time placing the sticks to them. If the soil is of a light nature, a mulch of stable-litter, half-decayed, alongside the rows of Peas, and also of Beans, will benefit the plants, keeping them cropping for a longer time than is likely to be the case without it. Let the Pea-quarter be kept clean, and the land stirred with the hoe in dry weather.

Out-of-door Tomatos.—The present is a suitable time to set out Tomato-plants on vacant spaces on the warmer fruit-walls. There are various methods of securing them in position. I use a stout stake to each plant, 4½ feet in length, and fasten the stem to this with broad strips of matting; others fasten to the wall with shreds and nails. It is better to nip off the lateral shoots as fast as they appear; and when the desired number of clusters are set, nip out the point of the stem. Afford abundance of water at the roots in dry weather, after the fruit is advanced somewhat.

Celery.—The plants intended for the early supply of heads should now be planted in heavily-manured trenches, in single or double lines, affording not less distance than 8 inches from plant to plant. Continue to prick out from previous sowings, and sow seeds for the latest supply.

Potatos.—It is very necessary to keep the hoe at work between the rows, and to mould up all of the early varieties. Sets of Early Kidney varieties may still be planted, and the produce will be found useful in the kitchen, and it will serve also for sets for next year.

Lettuces.—Spring-sown Cus Lettuce, unless it be of those kinds that require no tying, should have timely attention in this respect, and when the tying is finished let rapid growth be encouraged, hoeing the land and affording water, if necessary, and spraying the plants in the evening. Transplant some of the plants raised from March-sown seed. My practice is to sow the seed thinly and not transplant. Weekly sowings should be made during June and July, choosing cool moist parts of the garden for these crops.

Parsley.—The flower-stems on last year's Parsley plants should be cut off low down, unless seed be required, and then care should be taken to select for this purpose the finest curled only. Thin out spring-sown Parsley to 6 inches from plant to plant, and make another sowing out-of-doors, and in cold frames and boxes in the open air.

APPOINTMENTS FOR JUNE.

THURSDAY,	JUNE 2	—Linnean Society, Meeting.
FRIDAY,	JUNE 3	—Royal Botanic Society (Lecture).
SATURDAY,	JUNE 4	{ Isle of Wight Horticultural Society, Meeting.
TUESDAY,	JUNE 7	{ Scottish Horticultural Association, Meeting.
WEDNESDAY,	JUNE 8	{ Royal Cornwall Agricultural Show (2 days).
FRIDAY,	JUNE 10	—Royal Botanic Society (Lecture).
SATURDAY,	JUNE 11	{ Royal Botanic Society, General Meeting.
TUESDAY,	JUNE 14	{ Royal Horticultural Society's Committee, Eastbourne Horticultural Society, Meeting.
WEDNESDAY,	JUNE 15	{ Yorkshire Gala and Horticultural Fête (3 days).
THURSDAY,	JUNE 16	{ Linnean Society, Meeting. Rose Shows at Colchester and Isle of Wight.
FRIDAY,	JUNE 17	—Royal Botanic Society (Lecture).
MONDAY,	JUNE 20	{ Royal Agricultural Show at Birmingham (4 days).
WEDNESDAY,	JUNE 22	{ Royal Jersey Horticultural Society's Rose Show.
THURSDAY,	JUNE 23	{ National Rose Society's Exhibition at Bath. Bath Rose and Begonia Show. Ryde Rose Show.
FRIDAY,	JUNE 24	—Royal Botanic Society (Lecture).
SATURDAY,	JUNE 25	{ Windsor and Eton Rose and Horticultural Show. Royal Botanic Society, General Meeting.
TUESDAY,	JUNE 28	{ Royal Horticultural Society's Committee. Royal Horticultural of Southampton Exhibition (2 days). Rose Shows at Leeds and Sutton.
WEDNESDAY,	JUNE 29	{ Croydon Horticultural and Rose Show. Richmond Horticultural Society's Show. Canterbury Rose Show.
THURSDAY,	JUNE 30	{ Royal Horticultural Society of Ireland, Exhibition. Rose Shows at Eltham, Gloucester, and Norwich.

SALE FOR THE ENSUING WEEK.

FRIDAY, JUNE 3 { Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—58° 4'.

ACTUAL TEMPERATURES:—

LONDON.—May 25 (6 P.M.): Max., 59°; Min., 47°.

PROVINCES.—May 25 (6 P.M.): Max., 56°, S. West Counties; Min., 47°, Aberdeen.

The Temple Show.

It is a little difficult to speak with confidence as to the Temple Show, held this week. This much we may say, that although it was excellent, we do not think it was quite equal to what we have seen on former occasions, especially in the Orchid department—but then we heard others express the opinion that it was better. Certainly it was not quite so large, sundry gaps being visible, but that is not a subject for regret; rather should we be glad if the quantity shown had been less, and the grouping less crowded and more effective. The quality throughout was good, and we do not think we shall err if we say that the quality of the Vegetables in particular was unusually fine. This remark applies alike to the gardeners' exhibits and to those from the trade. Messrs. SUTTON's exhibit of Peas was especially remarkable. We cannot here enter into details, which find a place in another column. Messrs. SANDER's new plants, especially their new *Acalypha Sanderi*, found many admirers, but these have already been figured and described in our columns in connection with the Ghent Show. One plant, however, we must pick out for special mention here, as it was not shown at Ghent; we mean *Dracaena Van der Biltii*, a very handsome species with

tufts of long linear leaves striped with yellow and green.

The new *Pandanus Sanderianus* was shown in a fine example, which shows that the plant is likely to have a future as a decorative-plant.

Among Ferns, Mr. MAY's *Phlebodium Mail* was very remarkable for its pinnately-lobed and glaucous foliage. We give an illustration of it in another column, and note it as one of the most decorative of its class.

Messrs. DICKSONS of Chester showed a remarkable *Dracaena*, under the name of *D. Kippii*, with very narrow linear recurved deep purplish-red leaves.

Messrs. WALLACE, of Colchester, showed several plants of a new Lily, *L. rubellum*, described by Mr. BAKER in another column, having the colour of *L. Krameri*. A figure is given in another place (see fig. 128, p. 335). The plants at present are small, but very promising.

Messrs. VEITCH showed fine groups of *Caladiums*, a remarkable collection of hardy flowering shrubs, some of which we figure in the present issue, and a noble series of hybrid *Phyllocacti*, forming a most brilliant feature. Among the shrubs were *Hydrangea Hortensia* var. *Mariesi*, with very large rosy-pink flowers; *Philadelphus coronarius* *Boule d'Argent*, with funnel-shaped double white flowers; *Zenobia speciosa cassinefolia*, an old but most desirable plant for the shrubbery.

We do not specially look for fruit at the Temple Show, but Messrs. RIVERS' and Mr. HUDSON's pot-trees of this season's growth, and Messrs. BUNYARD's Apples of last year's ripening, were each in their way remarkable. The so-called hybrid Strawberry-Raspberry shown by the last-named exhibitor appears to be a species of *Rubus* pure and simple, with little or no trace of the Strawberry in it.

Roses are always a feature at the Temple Show, and when we mention the names of CANT, MOUNT, the PAULS, RUMSEY, and TURNER, it will be obvious that no falling off was likely to occur.

Messrs. SMITH, of Worcester, staged their fine *Clematis*, but we should be glad to see them now trained in some other fashion. Messrs. JACKMAN's *coccinea* hybrids were very interesting, if not so showy as the larger-flowered varieties. *Duchess of Albany*, with rose-pink flowers, was a specially pretty form.

The little rock-gardens devised by Messrs. BACKHOUSE and CHEAL were, as usual, delightful. In the former exhibitor's group were some very choice specimens, such as *Eritrichium nanum*, *Edraianthus serpyllifolius*, *Lewisia rediviva*, and many others.

It is not our object, however, in this column to give details which belong more appropriately to our report, suffice it if we here congratulate the Society once more on the success of its Temple Show.

A word to the Victoria Medallists—would it not have been fitting if those gentlemen honoured with this decoration had worn it on this occasion? It is meaningless, or it is significant; in the latter case, it should on this occasion have been borne by those entitled to it.

LINNEAN SOCIETY.—The anniversary meeting was held on Tuesday last, when the President, Dr. GÜNTHER, was re-elected, as also the other officers of the Society, and certain changes were made in the Council, according to the statutes. The President gave an interesting summary of our knowledge of the gigantic land tortoises, and at the end of his discourse presented the Linnean Medal to Dr. WALLICH for his researches into the biology of

the deep seas, and other contributions to science. A very interesting feature of the meeting was the presentation of a special Medal to Sir JOSEPH HOOKER on the completion of his *Flora of British India*. Dr. GÜNTHER briefly recounted the services to science rendered by Sir JOSEPH, and alluded to his work as Director of the Royal Gardens, Kew, President of the Royal Society, and of the British Association. Sir JOSEPH was evidently touched by the warmth of his reception, but looked as though the *Flora of British India* was not to be the last of his works, his upright figure and clear voice betokening a capacity for further work. Sir JOSEPH spoke of his election to the Society at a very early age when he was the youngest Fellow, then how he was the youngest member of the Antarctic Expedition under Captain ROSS, and had become the oldest by efflux of time. Sir JOSEPH touchingly alluded to the advantages he had received from the training and the example of his father, and ended by giving some interesting reminiscences of the former history of the Society. The meeting was graced by the presence of LADY HOOKER, and other lady members of the family, a special resolution of the council having, we believe, been obtained for this deviation from established rule.

— At an evening meeting to be held on Thursday, June 2, 1898, at 8 P.M., the following papers will be read:—I. "Notes on some Lories," by Prof. ST. GEORGE MIVART, F.R.S., F.L.S., &c. II. "A Revision of the Genus *Symbplepharis*," by Mr. E. J. SALMON. III. "On the Food of the Uropoda," by Surg.-Capt. H. A. CUMMINS, F.L.S., &c.

THE SURVEYORS' INSTITUTION.—The annual general meeting of the Institution, to receive the report of the Council, and the announcement of the result of the election of officers for the ensuing year, will be held on Monday, June 6, 1898, at 3 o'clock. The prizes awarded to successful candidates, in connection with the recent preliminary and professional examinations, will be presented by the President at the annual general meeting.

GREAT ROSE SHOW OF THE RICHMOND HORTICULTURAL SOCIETY.—We understand that the twenty-fourth annual exhibition of plants, flowers, fruits, vegetables, table decorations, &c., will be held in the Old Deer Park, Richmond, on Wednesday, June 29. In addition to the usual prizes and special prizes, there will be a Challenge Cup for Roses, presented by the Mayor and Mayoress of Richmond, Councillor and Mrs. ALBERT CHANCELLOR. His Royal Highness the Duke of CAMBRIDGE, T.R.H. the Duke and Duchesse of ORLEANS, and the LORD MAYOR and LADY MAYORESS of London have, amongst others, already intimated their intention of being present. The honorary secretary is Mr. A. ALGERNON CHANCELLOR, 1, King Street, Richmond, Surrey.

BOTANY IN SCHOOLS.—We learn that the report from the British Embassy at Berlin, with reference to the supply of flowers from the public parks there to the schools, for the study of botany, came before the School Board for London on the 20th inst., when it was decided that letters should be sent to the London County Council and Her Majesty's Office of Works inquiring whether a similar arrangement might not be made in this country. We wish this new departure all success.

THE MARKET GARDENERS, NURSERYMEN, AND FARMERS' ASSOCIATION.—First list of sums paid or promised in aid of Fund for appeal to the House of Lords; Agricultural Rates Act, 1896, Rating of Glasshouses, SMITH and Others v. RICHMOND:—Kelway & Son, Langport, £1 1s.; C. Martin, Worthing, £1 1s.; E. E. Sparkes, Worthing, £1 1s.; W. R. Marshall, Bognor, £2 2s.; John Turtle, Welling, £2 2s.; Norman Davis, Framfield, £2 2s.; E. Sawyer, Lower Edmonton, £1 1s.; E. Bachelor, Harrogate, £1 1s.; C. Whiting, Hereford, £2 2s.; A. Campbell, Southport, £1 1s.; Wm. Iceton, Roehampton, £5 5s.; G. Underwood, Camden Town, £5; Turner Bros., Garston, £2 2s.; W. A. Cull, Tottenham, £2; Ord Bros., North Shields, £1; J. Backhouse, York, £2 2s.;

FIG. 119.—ZENOBIA SPECIOSA CASSINEFOLIA : HARDY SHRUB ; FLOWERS WHITE,
LEAVES GLAUCCUS.

(As exhibited at the Temple Show.)

FIG. 120.—*HYDRANGEA HORTENSIA STELLATA*, VAR. *FIMBRIATA*.
(As exhibited by Messrs. J. Veitch & Sons at the Temple Show.)

FIG. 121.—*PHLEBODIUM MAYII*.
(As exhibited by Mr. H. B. May at the Temple Show.)

FIG. 122.—HYDRANGÆA HORTENSIA, VAR. MARIÆSII: HORT, VEITCH.
(As exhibited at the Temple Show.)

FIG. 123.—*PHILADELPHUS CORONARIUS*, "BOULE D'ARGENT."
(As exhibited by Messrs. J. Veitch & Sons at the Temple Show.)

FIG. 124.—*ADIANTUM HEMSLEYANUM*.
(As exhibited by Mr. H. B. May at the Temple Show.)

FIG. 125.—*AZALEA AMENA*, MIKADO.
(As exhibited by Messrs. J. Veitch & Sons at the Temple Show.)

J. Tully, 'Enfield Highway, £1 1s.; Fromow & Sons, Chiswick, £10; S. Brandon, Addlestone, £2 2s.; J. Byatt, Hampton, £2 2s.; J. L. Leigh, Newton-le-Willows, £3 3s.; J. Peed & Son, West Norwood, £1 1s.; Veitch & Son, Exeter, £1 1s.; G. Bennett, Hanwell, £1 1s.; A. F. Hobbs, Dunstable, £1 1s. Thirty-six Worthing growers on the basis of their rating (say) £100. The association has determined to proceed with the appeal, although the response to the application for funds has not been so general as the importance of the matter demands. Assistance is solicited from the numerous growers who have not yet contributed. *George Monro, Hon. Treasurer, 32, King Street, Covent Garden, W.C.*

GHENT SCHOOL OF HORTICULTURE.—We learn that a party of students of this Institution, conducted by the Head Gardener, will visit this country between June 1 and June 6. They purpose visiting the establishments of Messrs. VEITCH, WILLIAMS, and others, and the Royal Gardens, Kew. It is hardly necessary to bespeak for them a cordial welcome, but we regret that earlier intimation could not have been given.

THE AGRICULTURAL SEED TRADE ASSOCIATION held its annual meeting on Monday, the 16th inst., at the office of the president, Mr. J. PICARD, 59, Mark Lane, when the usual business of presenting the report, cash accounts, election of officers for the year, and other matters were transacted. It was also decided to hold the annual dinner at the Holborn Restaurant, and Mr. JOHN HARRISON, of the firm of HARRISON & SONS, Leicester, was thereon elected Chairman for the occasion. Monday last, May 23, was the day fixed for the function, when about thirty members and friends attended, including Mr. N. SHERWOOD (Vice Chairman), also Messrs. A. MOSS, T. THORNTON, H. LE MAY, W. LE MAY, H. AITON, G. BELL, E. MARCUSE, D. ALLESTER (Secretary), and others. In proposing prosperity to the Association, the chairman remarked that it deserved to be better known, and more largely patronised, as it had for its objects the elements for securing a good understanding amongst those engaged in the trade, and providing a permanent Arbitration Board available to all for the purpose of settlement of trade disputes in having a code of rules by which the Agricultural Seed Trade should be carried on. It being the duty of all engaged largely in the trade to join and support the Association, he hoped many who were not members now would soon join; announcing, at the same time, three firms who had recently consented to do so. The Society was established by a few London firms eighteen years since, but now it admits members from all parts of the United Kingdom. Each year the cases for arbitration have become fewer in number, and a law suit seems to be almost a thing of the past, clearly proving the great value of the Association, and the beneficial effects of its influence.

SAN JOSÉ SCALE.—Canada has, we learn, already taken defensive steps against the introduction of this pest from the United States, and now further measures are to come into force, the chief points of which are the following: the introduction of all trees, bushes, plants, Vines (plants), shoots, cuttings, layers from the United States of America, Japan, Hawaii, and Australia. The exceptions are, glasshouse plants, herbaceous plants, Conifers, bulbous and tuberous plants. All plants, &c., seized at the frontier or at the port of arrival will be confiscated and the importers fined, as well as mulcted of the import duty. The executive is empowered when sufficient reason exists to extend the regulations or to repeal them.

H. WITTE.—The hortulanus, M. H. WITTE, of the Leyden Botanic Garden, after forty years of productive activity, has been pensioned. His son M. E. TH. WITTE, succeeds him.

SCILLA CAMPANULATA VAR. COMPACTA ALBA AND S. C. VAR. ROSEA.—We are indebted to Messrs. E. H. KRELAGE & SON, Haarlem, for flowers of two new

varieties of *Scilla campanulata*, which show a considerable advance on the common garden varieties of the same colours, of which some flowers were also sent for comparison. The white variety, *Scilla campanulata* var. *compacta alba* (Krelage), has large bell-shaped flowers, and the floral trusses are much larger than in the common white variety. The other novelty, *Scilla campanulata* var. *Rose Queen* (Krelage), is a decided advance on the rosy forms hitherto cultivated, which might have been improved long ago. These two *Scillas* are admirable additions to spring-flowering plants.

A NEW VARIETY OF CHRYSANTHEMUM MAXIMUM.—We have received an improved variety from Mr. J. DAVIES, Hoylake, Cheshire, to which he has given the cognomen *Daviesii*. The variety is valuable as an early and very abundant flowerer. Mr. DAVIES tells us that his two large beds of the plants are at the present time a sheet of white bloom. The first flower opened on May 7, therefore much earlier than any other. It is a fine showy white flower with a yellow disc.

THE NEILL PRIZE.—This much-valued prize, the highest a Scottish gardener can aspire to, was founded about forty years ago by the late Dr. PATRICK NEILL of Edinburgh, by vesting a sum of money now realising about fifteen guineas annually. In accordance with Dr. NEILL'S desire the proceeds are awarded every second or third year, at the discretion of the Council of the Royal Caledonian Horticultural Society, to a distinguished Scottish botanist or cultivator. Some of the most distinguished of Scottish botanists and horticulturists have received the honour during the past; and the prize for 1897 and 1898, was awarded at a meeting of the Council of the Society, on Wednesday 18th inst., as we recorded last week, to Mr. THOMAS LUNT, the well-known and accomplished gardener to Sir MICHAEL SHAW STEWART, Bart., Ardgowan, Renfrewshire. Mr. LUNT, who is still in the prime of life, has been in charge of the gardens at Ardgowan for the long period of forty-five years, and besides keeping his extensive charge in perfect order for such an unusual period, is widely-known and highly esteemed among his numerous friends. His services as a judge are highly appreciated, and have been freely and ably given at the shows of most of the leading Societies in the country. Long may he enjoy his well-merited honour. Those who have formerly received the prize are the following:—

Cultivators.—Mr. James McNab, Curator of the Royal Botanic Gardens, Edinburgh, and Superintendent of the Society's Experimental Gardens; Mr. Wm. Thomson, gardener, Dalkeith Park; Andrew Turnbull, Bothwell Castle; Robt. Foulis, Fordel; John Webster, Gordon Castle; David Thomson, Drumlanrig; Wm. Young, Assist. Sec. of the Royal Caledonian Horticultural Society; Malcolm Dunn, gardener, Dalkeith Palace; Angus McLeod, Newbattle Abbey; John Paterson, Millbank; Alex. Kirk, Alloa.

Botanists.—Professor Balfour, Edinburgh; Mr. John Sadler; Mr. Isaac Anderson Henry of Woodend; Charles Howie, Upper Largo, Fife; Professor Bayley Balfour, Edinburgh; and Mr. Robert Lindsay, late Curator Royal Botanic Gardens, Edinburgh.

YORKSHIRE NATURALISTS' UNION.—The 137th meeting of this body, of which the president is Prof. MICHAEL FOSTER, M.A., Sec.R.S., Cambridge; hon. secretary, W. DENISON ROEBUCK, F.L.S., 259, Hyde Park Road, Leeds; and special hon. secretary for this meeting, H. H. CORBETT, M.R.C.S., 9, Priory Place, Doncaster, will be held at Doncaster for the investigation of Balby, West Moor, Armthorpe, Sandal Beat, Sandal Brickfields, Wheatley Wood, &c., on Whit-Monday, May 30, 1898. Railway arrangements: through return tickets at pleasure-party rates will be issued at all stations on the G.N., H. & B., L. & Y., L. & N.W., M. S. & L., Midland, and N. E. Railways, which have booking arrangements for Doncaster station to members and associates of the Y.N.U. producing their signed card of membership. Tickets taken on Friday, Saturday, Sunday, or Monday, May 27 to 30 inclusive, will be available for return any day up to Tuesday, May 31. Where through

bookings are not in operation, members may book to most convenient junction, and re-book to destination, the reduced fares being available for each stage of the journey. Hotel accommodation: members will find excellent accommodation at The Glyn (Temperance), Head-quarters; The Angel, The Elephant, The Reindeer, &c. On Saturday evening, May 28, an informal meeting and exhibition of objects of local scientific interest will be held at The Glyn Hotel.

PUBLICATIONS RECEIVED.—*Garden-Making*, by L. H. Bailey (Macmillan); *Handbook of Practical Botany*, by E. Strasburger, edited by W. Hilhouse (Swan Sonnenschein); *British Orchids*, by A. D. Webster (J. S. Virtue & Co., Ivy Lane, E.C.).—*Greenhouse Management*, by L. R. Taff (New York, Orange Judd Co.; and to be obtained from Kegan Paul, Trench, Trübner & Co., Paternoster House, Charing Cross Road, W.C.).—*Deboscheriana*; a Reply to M. Charles de Bosschere (Brussels, P. Weissenbruch, 45, Rue du Poinçon).—*Fruit-growers Annual*, by Sampson Morgan (London, Iliffe & Sons, 3, St. Bride's Street, E.C.).—*Nuovo Giornale Botanico Italiano*, Nuovo Serie.—*Thirty-fifth Annual Report of the Michigan Agricultural College Experiment Station* (Lansing, Robert Smith Printing Co.).

HOME CORRESPONDENCE.

ANNUAL DIANTHUSES.—It appears difficult to adequately commend to the notice of lovers of flowers the many interesting forms of *D. chinensis*. It is also difficult to name another annual that is so easy to raise and grow, so quick to bloom, so showy, and so lasting. The species, which has been in cultivation in this country for nearly two centuries, originally came from China, and, with the exception of doubling the flowers, increasing the size somewhat, and extending the varieties, no great change has taken place in it. But they can be made to form charming patches of colour in the garden, and if the plants can be raised in frames, and are then transferred to beds of good soil, and at regular distances apart in the beds, they become very effective; especially if a little attention be given in the way of removing the decaying flowers, so that seed-pods be not formed, then the duration of the bloom is increased. Varieties of *D. chinensis*, both double and single, have been raised and named; but since the introduction of that greatly enlarged form, *D. Heddewigi*, just forty years ago, the smaller-flowered and less brilliant forms of *D. chinensis* have fallen back to the second place in degrees of notice. In this case the Japanese seem to have developed a new type of the Chinese annual *Dianthus*, as they did of the *Chrysanthemum*. It was M. Heddewig, of St. Petersburg, who obtained seeds of this new form from Japan, and some were sent to Messrs. Carter & Co., of Holborn, who were the first to flower it and exhibit it in public. The first bloomed seedlings showed variation in colour, and the petal edges were slightly toothed, and this characteristic becoming developed, a handsome form, lacinated on the petal edges, was developed; and thus originated the type known as *laciniatus*. In the case of varieties of the original type, flowers have been developed with almost, if not quite, smooth petal edges, and varieties selected and named; and double forms also have resulted. Some of the best of the single varieties which come pretty true from seed are *Crimson Belle*, bright red; *Brilliant*, of a deeper and more lustrous crimson; *Eastern Queen*, having a very pleasing tint of rose, and such double forms as *white*, *purple*, and that known as the *Mourning Pink*, the purple flowers being edged with white. The type *Heddewigi* has been crossed with the *Sweet William*, and also with *chinensis*, and some fine double forms have resulted, and these are grouped under the section *hybridus*; while a larger group known as *imperialis* may be regarded as glorified *Sweet Williams*, having compact, fully double blossoms. Of this type there are several varieties, *white*, *striped*, *crimson*, &c., and there is also a dwarf strain with several varieties. Thus there is ample choice, and lovers of the best and most lasting of the hardy annuals should include the annual *Dianthus* in a selective collection. We starve our annuals too much. They are often sown much too thickly in poor soil. They are allowed to grow and flower unthinned, and when they bloom they are too

frequently fugacious and unsatisfactory. Good cultivation works wonders, and no other hardy annual perhaps more appreciates good culture than *Dianthus chinensis*, and its numerous progeny. *R. D.*

YELLOW-FLOWERED MARGUERITES.—I always read with much interest and benefit Mr. Ward's notes. In your issue of the 14th inst. he deals with Violets and yellow Marguerites for market-work outdoors. What I am surprised to learn is, that he winters his autumn-struck cuttings in cold frames. I scarcely thought they would stand this; but my object in writing this is to ask him, through the *Gardeners' Chronicle*, if he would give me, as well as many other amateurs, a short cultural note on growing yellow Marguerites in pots for winter and spring flowering. I have tried to produce plants such as one sees brought to market, but I have found it the most unsatisfactory plant to deal with. I have plants in all stages of growth, but not one flower have I had during winter or spring out of the lot. Possibly I have been trying to do the impossible. I have tried it in all temperatures. The plants grow like weeds. I cut back half the batch some time ago, thinking as I got the wood older and riper the young growths would burst into flower; but all they do is to increase in bulk. I grow three varieties, the small, flat-flowered sort, also a variety I picked out of a batch in the market a year ago, as it was not pegged down in the pot, as all the others were, and therefore, as I thought, a dwarfier sort. But under my bad culture, as I conclude, it seems, so far as its offspring is concerned, to have lost its dwarf character; the foliage is coarse and succulent looking. What the variety is I do not know. Lately I bought in a variety which I was told is the best, and named Feu d'Or; whether this will be more reasonable in its requirements, in order to get it to flower during winter and spring, I cannot say. I have just struck a batch for next winter flowering; I propose to treat these as one does zonals for winter-flowering. I know I should be, and I am certain many others would be, indebted to the *Gardeners' Chronicle* for a Cultural Note on "How to Grow Yellow Marguerites for Winter and Spring Flowering." Of course, I mean plants in shape and form such as the market-men produce, with level heads a mass of bloom. *A. E.*

GARDENERS' ORPHAN FUND.—As one who has in times past taken some interest in this Fund in connection with the concert scheme of assistance (a scheme, most unfortunately, now in abeyance), I read the remarks of your correspondent in connection with this very deserving charity with much interest. Yes, it is a very lamentable fact that the Fund is not supported at all as it should be by members of the craft. I would venture to give expression to the opinion that the executive committee of the Fund are not altogether blameless for this truly unfortunate state of affairs. The majority of working gardeners are absolutely shut out from participating in what should be a genuine gathering of gardeners in connection with their own fund at the Annual Dinner by reason of the prohibitive price fixed to ensure attendance thereto. True, those who attend do not forget the appeal made to them; but such substantial aid is very dearly purchased if it shuts out those who should be the main support of an institution that was specially designed to relieve the orphans of gardeners—an institution that is certainly ignored by the main body. Why not—as in the early days of the Fund—have a really genuine gardeners' gathering, with the price of admission to it suited to the means of gardeners? And why does not the committee strive to get young gardeners to take an interest in a fund that may have special claims upon their support? *Life Member.*

PROTECTING PEACH-BLOOM.—When a few days since at Dropmore, where Mr. Herrin has Peach-trees on the open wall, on high and on low ground, some distance apart, I observed that there were on the trees remarkable sets of fruit in every case. Naturally I asked, "Did you give these trees any protection when in bloom?" and he said "Yes, when in full flower I hung over them fish-netting doubled." That was one for the protectors. But whilst in the upper garden there is but a south wall, in the lower garden there is a west wall also, and on this are numerous Peach and Nectarine-trees, also carrying heavy sets of fruit. Here it was only the rather earlier-bloomed trees on the south walls that had net protection, the west wall not getting any; and this is on low-lying ground. Therefore this is a point in favour of the net protectors, as it leads to the inference that such protection as was given, little enough after all, did no good, and was so much useless

labour. On some of the trees where thinning had not yet been done, the fruits would have to be reduced by about three-fourths. I noticed that none of the trees are luxuriant. That luxuriance is a bad feature in Peaches always, and accounts very often for failures to set bloom, is a matter of common knowledge. Generally outdoor trees get too much digging about, and too liberal manuring. The late Mr. Lindsay when at Ditton Park, Slough, was one of the most successful Peach-growers on outside walls, having no Peach-houses. His wall was always a fine picture in the autumn when full of fruit, and he had no elaborate means of protecting his trees. Generally they had none at all, and the results were of the best. *A. D.* [Our experience of south country gardens, and more especially those round town, shows that, in a season like the present following a mild winter, but little protection is needed, but in a cool spring following a hard winter, protection has a good deal to do with securing a crop of Peaches, Nectarines, Apricots, Pears and Plums, &c. The reason may be that the severe cold of what is called a "hard winter" extracts the sun-heat from the soil, whilst after a mild one, marked probably by heavy or but little rain, some of the latent heat is still there, to aid in warding off the ill effects of such spring frosts as we may chance to get. *Ed.*]

TRAMPLING ON AN ONION-BED.—While reading Mr. McHattie's article anent spring-sown Onions, it recalled to mind a "wrinkle" imparted to an old friend, a worthy schoolmaster, in the North. The said "wrinkle" was, that when the Onions were about 2 inches in length, he was to firmly tread, not between the rows, but on the plants. "This," says the Dominic, "I decided to try; but thinking it such a cruel procedure, and to mitigate its more crushing effect, I took off my boots, and carried out the process in my stocking feet." Unfortunately, I never found out how the "wrinkle" succeeded, so cannot advise as to its efficiency. *J. McCullum, Dorincourt Gardens, Whyteleafe, Surrey.*

PROTECTING PEACHES, ETC.—In reference to your correspondent "A. D.'s" note on this subject in the *Gardeners' Chronicle*, May 14, I may state that I have followed the practice of covering for several years past. I agree with "A. D." that night frosts are undoubtedly what we have mostly to contend with, and hailstorms by day occasionally. I have no doubt in the low-lying country around Lincoln, where frosts are more severely felt than on higher lands, it is absolutely necessary to protect the trees. Of course, it is equally necessary to take away the covering early in the morning. My experience of Apricots here is, that to cover them usually ensures abundance of fruit. This year the fruit set thickly in clusters all over the Apricot trees, and I have pulled off quite six for every one left, and still have a heavy crop. Last year the show of blossom was not so good, but I got a good average crop notwithstanding; and the year before I had a very heavy crop, similar to this year's. I must say, that unless I had protected the trees this year when the frost exceeded 16° for several nights at the time when the trees were in bloom, the fruits would have been very few. Our Apricot-trees are unusually healthy, and the heavy showers have kept them clean and soaked the ground. The Peaches, however, are not nearly so healthy, although there is a good set, but the cold nights have caused curl to appear on the leaves; they will with warm weather grow out of this state, and make good progress. *M. Cooper, Boultham Hall, Lincoln.*

A SOUTH DEVON GARDEN.—My garden has been very gay with *Narcissus* and *Anemone fulgens*, but they are now all over. Roses are well in bud, and *Pyrethrums* promise well. *Buddleia globosa* is coming into flower. *Primula Sieboldi* (pink) has been out all winter, and is now blooming freely. *Mandevilla suaveolens*, out all winter, is growing well, but I doubt if I shall flower it, as the plant is too much exposed. It flowers well all over a neighbour's front verandah, well protected behind some old Myrtles and Pomegranates. A friend has just taken me to see his young plant of *Embothrium coccineum*, in this village, just 10 feet high. I counted eighty-four trusses of bloom—there may have been more. It is the most glorious thing I know. Mr. T. B. Bolitho, M.P., has much larger plants both at Greenway on the Dart and at Ire-widden, near Penzance; and his cousin, T. R. Bolitho, has also a large plant at Trengwainton. The largest plant I know is at Trellisick, but it was not in bloom when I was there. I have *Heuchera coccinea* in flower and *Ourisia* coming out, also *Ixias*. *W. Thomson, Bishop's Teignton, Teignmouth.*

DOUBLE WHITE AURICULA SNOWDROP.—The plant of this exhibited at the Temple Show represents some twenty years of patient selection. I began at that distance of time with a plant which had white single flowers, but which occasionally threw a flower or two showing an extra petal issuing from the tube. The first two-year seedlings for these semi-double varieties produce seed fairly freely, showed but little change; but twelve years afterwards I secured a very good double white, which I unfortunately lost. It was like beginning the work over again, and having one or two semi-doubles by me, I made further attempts, keeping two or three of the best of the whites as seed-bearers. It was curious to note that seedlings from white flowers only would for two or three generations show no trace whatever of white; and then, when I feared I had lost the line of descent, a white would appear, and my persistence be rewarded. It was in the year 1896 that the variety Snowdrop appeared, which it must be admitted is fully double, as well as a robust grower. All the flowers of white Auriculas that I have yet raised open of a dull primrose tint, but gradually they bleach to white. Owing to the dull, cold weather, the flowers of Snowdrop have been fully a month in unfolding. It is also interesting to note that the various relays of seedlings have given me splendid doubles—maroon, plum, yellow, blue, and mauve colour; and I have now a collection of a dozen double varieties, the like of which probably could not be found in Europe. The double Auriculas are all late-blooming, and generally at their best about the second week in May. *R. Dean, V.M.H.*

STRAWBERRY ROYAL SOVEREIGN.—Why has this variety become so popular for forcing? In the first place it has large fruits, and in advocating mere size I lay myself open to criticism, as many private growers condemn size if quality be lacking. I agree with them in a measure, but in these days, when size in fruit is so great a feature, in order to keep pace with the times, I fear we must not overlook size as one point. Royal Sovereign is not poor in quality when given the conditions necessary to the production of good flavour in other fruits. This season I have tasted fruits equal in quality to some of our best standard varieties, and I am sure that flavour, so far as this variety is concerned, largely depends upon the cultivation. Free-cropping is another cardinal point, and one very difficult to deny, and Royal Sovereign is easily first for this, being in weight of crop and average size of fruit very satisfactory. I very much doubt if such splendid fruits as Mr. Norman staged on the 10th at the meeting of the Royal Horticultural Society (see fig. 126, p. 331) have been seen previously, and his testimony as to the worth of this variety is strong. For years I grew *Auguste Nicaise*, a variety valuable for its size alone; but they are not at all regular in this respect, there being a few very large fruits, and many small ones. The foliage, too, is much subject to red-spider, and a variety with hard or smooth foliage is much less subject to green-fly and red-spider. Other points are firmness of the fruits, and Royal Sovereign has firm fruits, and when fruits are needed to send long distances, it is a great gain. I do not know of any variety that travels better. For the last few years I have been reducing my forcing varieties in favour of Royal Sovereign, and this was not done until repeated trials had convinced me of its worth. Now I pot it up in thousands, and if the fruits are well thinned at an early stage of growth, and they are finished with ample air and light, there is little fault to find with it in regard to size, quality, or crop. For the open ground the variety is equally useful, but I use young plants, as it grows so freely in one season, and the young plants crop so well, that there is no need to keep older plants. In the case of any older plants, I find it advisable to reduce the number of trusses. *G. Wythes.*

SOCIETIES.

ROYAL HORTICULTURAL. THE TEMPLE SHOW.

MAY 25, 26, 27.

THE great show of the year was, as usual, held in the Temple Gardens, through the courtesy of the Benchers. The arrangement was the same as on former occasions, and we believe the attendance of the public was larger than ever.

GROUPS OF PLANTS.

In the big tent, Messrs. G. JACKMAN & SON, Woking Nurseries, Surrey, showed an exceedingly pleasing group of

small-flowered Clematis plants, trained on balloon trellises. The varieties were Sir T. Lawrence, a crimson tubular flower, like those of *C. coccinea*, from which they are derived, the reverse of a duller hue; Duchess of York, bluish-coloured, also tubular; Admiration, puce, each segment furnished with a whitish central band; Countess of Onslow, bright purple; Grace Darling, rosy carmine; and Duchess of Albany, light and deep shades of rose. There were several plants of each variety, and arches were thrown over towards the back of the group, on which plants of *C. Countess of Onslow* were trained, thus relieving the otherwise stiff ensemble. The varieties represent a new type of hardy Clematis, and were well grown and furnished with foliage and blossoms.

Mr. W. ICETON, Putney Park Lane Nursery, S.W., exhibited a good-sized miscellaneous group, consisting of *Dracæna Sanderiana*, *D. australis variegata*, *D. Doucetti*, *Codiaeum Weissmanni*, a number of *Caladiums*, with brilliantly-coloured leaves; *Ericas*, *Kalosanthes* in variety, very fine Lily of the Valley, as cut flowers; *Mandarin Oranges*, *Adiantums* in variety, *Azalea mollis*, and *Lilium longiflorum* var. *Harrisi*, the group being backed with Palms, *Araucaria excelsa*, Bamboos, &c.

Messrs. J. WATERER & SONS, Bagshot, Surrey, had a corner exhibit of *Rhododendron hybridum*, consisting of plants ranging from 2½ to 6 feet in height, and most floriferous. We noted *Baroness Henry Schroder*, pale blush with a patch of purple hued spots on the upper segment; *Duchess of Connaught*, of a creamy-white tinge adorned with a patch of

variety, as round-headed bushes, was made much use of. *Ceanothus Veitchianus* (own raising), with the habit of *C. rigidus*, and numerous short spikes of blue flowers, is a pretty subject. *Rosa Wichurae Manda's Triomphe*, belongs to the *Rosa Polyantha* section, and has small white flowers that come in loose panicles. *Eremurus himalaicus* was a plant that was freely used in the group. Its shaft measures, including the floral portion, some 5 feet in height; and the flowers are white, small, and densely arranged, a fine border or rockery plant. *Lycium barbarum foliis variegatis* is a desirable plant for the wild garden, and the variegation is creamy-white on green. *Fabiana imbricata* was shown in bloom, also several *Cytisus*, including *C. scoparius* var. *Andreas*, *C. s. grandiflorus*, *C. s. piæcox*, and *C. purpureus*; *Eulalia japonica gracillima*, a strong-growing (4 feet) green grass, probably of use in decoration as a pot plant. *Vitis heterophylla foliis variegatis*, *Yucca gloriosa variegata*, a distinct variety of Adam's Needle; *Rhapiolepis japonica* in a well bloomed example; *Arundo Donax variegata*, *Spirea Anthony Waterer*, with corymbs of flowers of a deep crimson colour, abundantly produced; and *Rhododendron hybridum Helene Schiffner*, with pure white flowers. The back of the group was furnished with *Prunus Pissardi*, Japanese, and other Acers, &c.

Messrs. J. VEITCH & SONS exhibited in the small adjoining marquee a number of *Codiaeums* (Crotons), showing the perfection of cultivation, the leaves clean, fresh-looking, and

Messrs. CANNELL & SONS, Swanley, showed 150 *Cannas* in about forty varieties of these showy plants. Quite new are *Leon Vassilière*, the largest of its kind, scarlet, with dark-coloured foliage; *Britannia*, yellow with a patch of scarlet on the central area of each segment. Of slightly older varieties, we remarked *Italia*, *Paul Meylan*, *Beauté Poitevin*, *Aurore*, *General Miribel*, *Reich's Kanzler Fürst Hohenlohe*, flowers of a soft yellow hue; *Comtesse, L'Etoile*, flowers yellow, densely spotted on all the segments; *Duchess of York* is similar to the last; and *Simon Queen*.

Messrs. F. SANDER & CO., Nurseries, St. Albans, showed a striking group of plants, most of which had been already shown at Ghent and figured in our columns, consisting of many examples of *Acalypha Sanderi*, with plenty of flowers on each (First-class Certificate); *Dracæna Vander Bilti* (two plants), like to, but dissimilar from *D. Doucetti*, the variegation being of a bolder kind, and the leaves longer; *Phoenix Roebelini*, *Dracæna Godseffiana*, *Licuala Jeanencyi*, two plants, a distinct looking species, *Acalypha Godseffiana*, *Pandanus Sanderi*, *Anthurium Novelty*, with a spathe, probably monstrose, which was of a green tint at the base, and the rest of the area deep crimson colour. An Award of Merit was recommended to *Areca Ilsemanii*, a very graceful Palm at present in a young state, the newest leaf being high coloured.

Messrs. R. & G. CUTHBERT exhibited a group of *Azalea mollis* × *sinensis* varieties, including *Anthony Koster*, flowers of a soft yellow tint; *C. Maa-chalk*, also yellow, a small flower, and some few others. *Azalea mollis* hybrids remarkable for colouring, form, or size of flowers, were *Gen. Goffinet*, with pink flowers; *Alphonse Lavallée*, with orange-scarlet ones; *Chevalier de Reati*, flowers of pale canary-yellow tint; and *Comte de Quincy*, with deep yellow-coloured ones. The rest of the group consisted of *Azalea rustica* fl.-pl., a considerable variety, all of which are beautiful subjects the American garden.

GROUPS OUT OF DOORS.

Hardy bare plants in out-of-doors groups were shown by Mr. JOHN RUSSELL, of the Richmond Nurseries, Richmond, Surrey, who also showed Japanese Acers in variety, variegated Ivies, *Trie Ivis* in variety, of various heights up to 2 feet; and *Euonymus latifolius albus*, a showy plant for masses or edgings.

Messrs. LITTLE & BALLANTINE, nurserymen, Carlisle, showed *Holly Golden King*, a companion-plant to the old *Silver Queen Holly*, which, as everyone knows, is a very slow grower. This new variety is robust, and of larger growth. The young leaves are "golden," and the older ones of a paler or creamy tint.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, had a group of *Rhododendrons* in bloom, interspersed with Bamboos of various species and sizes, from 2 feet to 10 feet in height.

Messrs. FISHER, SON & SINRAY, Royal Nurseries, Handsworth, Sheffield, showed a number of Japanese Acers, viz., *reticulata*, *rubrifolium*, *septemlobum*, and others, with an edging to the group of *Hedera spectabilis* var. *aurea*. An adjoining and much larger bed was filled with picture plants in variety, including Acers, *Prunus Pissardi*, variegated Ivies, *Cornus Späthi*, *Andromeda japonica albo-marginata*, *Corylus purpurea*, a useful if somewhat dull-purple-leaved hazel; *Alnus glutinosus purpureus*; a pretty lacinate-leaved Elder, *Sambucus racemosa plumosa aurea*; *Quercus macrophylla*, *Q. pannonica*, *Cornus sibirica elegantissima*, with effective silvery variegation; *Betula purpurea*, also an effective plant; *Amygdalus persica purpurea*, a purple-leaved Peach, an American introduction, and an improvement on *Prunus Pissardi*, in that the colour does not become dull with age. An interesting group of hardy trees and shrubs doing well in South Yorkshire, and consequently hardy enough for any part of the country.

Messrs. J. CHEAL & SONS, Lowfield Nurseries, Crawley, showed a group, in which were remarkable plants of *Azalea mollis*, of *Azalea amomæ splendens*, the latter the bright crimson flower of small size, and as numerous as in the type, a good plant for small beds and margins of bigger one; *Sambucus serratifolia*, a variety with very graceful foliage; *Andromeda formosa*, with nice-looking, attractive, bronzy, young foliage; *Acer platanoides purpureum*, and other Acers, including *platanoides Lindenii*, with creamy-white variegation; *Kalmia glauca*, a dwarf plant with corymbs of small rosy-hued flowers; *Acanthopanax pentaphyllum foliis variegatis*, a pretty subject requiring slight winter protection; several *Biotas*, *Cupressus*, *Thuas*, *Plagianthus Lyalli*, a plant 6 feet high; *Eurybia Gunni*, and a few *Rhododendron hybridum*.

Messrs. THOS. CRIPPS & SON, Tunbridge Wells Nurseries, showed a collection of Japanese Maples, in a few quite hardy varieties. The plants had been allowed to assume their natural habit of growth, and showed scarcely any trace of training, for this reason the more pleasing probably to many persons.

Messrs. BALCHIN & SONS, Hassocks Nursery, Sussex, made a magnificent group of such plants as *Erica Spenceri*, *E. ventricosa* in variety, *Boronia serrulata*, *B. heterophylla*, *Phenocoma prolifera Barnesii*, *Leschen alia biloba major*, and the purple-flowered, *Achimenes-lik Browallia elatior*. The cultivation represented by this group was most perfect, being equal at least to former exhibits from the same firm.

M. SMET DE VIVIER, of Mont St. Amand, Ghent, Belgium, exhibited a group of seedling varieties of *Anthurium Scherzerianum*, many of which were attractive, ranging from pure white to deep crimson. An Award of Merit recommended to a variety *Senateur Montefiore Leves*, the spathe being curiously mottled red and white.

FIG. 126.—STRAWBERRY ROYAL SOVEREIGN.

(Taken from fruits grown at Hatfield House by the Premier's Gardener, Mr. G. Norman.)

yellow spots; *Sappho*, white, with a dense purple patch; *Princess of Wales*, cerise, and white throat internally; *J. Marshall*, *H. Brooks*, with deep crimson flowers. Mrs. W. Agnew, Minnie, John Walter, W. E. Gladstone, rosy crimson, and numerous other old and fine varieties were included in the group.

Messrs. J. VEITCH & SONS, LTD., Royal Exotic Nursery, Chelsea, staged a very interesting collection of hardy plants, including amongst others, *Viburnum macrocephalum*, a plant furnished with about a score of heads of white blossoms, the height of the plant being 2 feet; *Hydrangea Hortensia Mariessi* (fig. 122), large corymbs of flowers, surrounded by a row of barren flowers, of a pale-pink colour; *H. Hortensia rosea*, not so effective, but similar to the first named; *H. Hortensia rosea*, a brightly coloured variety of this common species, with large corymbs of flower; and *H. Hortensia stellata fimbriata* (fig. 120), pinkish-white, the corymbs consisting entirely of barren blossoms, and consequently an effective plant; *H. paniculata* var. *grandiflora*, has flowers somewhat exceeding the type in size. *Zenobia speciosa cassinefolia*, a plant well furnished with flowers (fig. 119); *Philadelphus Lemoinei*, small white blossoms abundantly produced; *P. coronarius Boule de Neige*, a striking variety with ivory-white blooms of a large size; *P. c. Candelabra*, white, is a desirable variety, as is also *P. c. Boule d'Argent* (fig. 123). *Azalea pontica* var. *Fama*, flower of pale pink and the plant most floriferous; *A. p. Gloria Mundi*, orange and yellow flowers; *A. p. Bouquet de Flore*, light yellow and orange-coloured flowers; *Azalea amomæ Mikado*, salmon-coloured flowers, very numerous (see fig. 125); *Azalea mollis* × *sinensis* T. J. Heide, with rich orange-scarlet flowers, *A. m. × s. Dr. Reichenbach*, similar to the last-named; *A. m. × s. M. Desbats*, very large blooms of an orange and pink tint. *Rhododendron Prometheus*, a richly coloured

of perfect form. We remarked the varieties *Prince of Wales*, one of the spirally-twisted-leaved section; *Flamingo*, green leaf, with a yellow-hued midrib; *Albert Truffaut*, leaf mottled yellow and green; *Eugène Chantrier*, *Aigburth Gem*, *Keedii*, an imposing variety, with entire leaves, coloured crimson-green when aged, marbled yellow when young; *Challenger*, long, broad leaves; *Hammondi*, semi-erect leaves, narrow, and channelled, green with a yellow midrib when young, and of a crimson hue when aged; *Hawkeri*, leaves half white and half green; *Golden Ring*, and *Schomburgkianus*. The remainder consisted mostly of older and better-known varieties.

Messrs. FROMOW & SONS, Sutton Court Nursery, Chiswick, had a group of Japanese Acers, grown as standards and dwarf bushes, very effective in their leafage and varied tints. Most of the varieties known in gardens were represented. The group was enlivened by the introduction of a few *Lilium longiflorum*.

Messrs. RICHARD SMITH & CO., Nurseries, Worcester, had as usual in recent years a grand group of trained Clematis in pots, including the snow-white variety of *C. Jackmani* section; *Madame Van Houtte*, white; *Mrs. George Jackman*, a very fine white variety, with flowers less starry than most Clematis; *Princess of Wales*, flowers of a fine blue, and of excellent shape; *Marie Lefebvre*, flowers of the lightest blue or mauve shade, a central line of a darker tint running down each petal; *Madame Edouard André* (of Jackman type), colour ruby-red; *Countess of Lovelace*, *Blue Gem*, *Enchantress*, *Belle of Woking*, a double flowered, of a light blue tint; *Lucie Lemoine*, a double white flower. *Purpurea elegans*, still one of the best of its colour, bluish-purple; *Gloire de St. Julien*, a very light violet-hued bloom; *La France*, of the lanuginosa section. The groups was faced with *Boronia alata*.

Mr. V. N. GAUNTLET, of the Green Lanes Nurseries, Redruth, showed fifty species of *Bambusa*, including beside better known ones *B. Boryana*, *B. marmorata*, *B. nobilis*, *B. aristata*, *B. vittata argentea variegata*; *Arundinaria Falcenri*, *A. auricoma*, *A. gracilis*; *Phyllostachys nigra*, *P. n. punctata*, *P. Castillonis*, *P. heterocycla*, *P. fl. xuosa*, and *P. aurea*. We are unable to say that the plants showed good cultivation, although they illustrated the capabilities of the Cornish climate.

CALADIUMS.

The group of *Caladiums* from Messrs. JOHN PEED & SONS, Roupell Park Nurseries, Norwood Road, S.E., was a very handsome one. Looking towards the back of the exhibit, where a row of Palms partially screened the side of the tent, the furthest plants were magnificent specimens of culture; and though they were not of the newest varieties, they represented either standard old ones, or gems that were novelties a few seasons ago. We noticed *Triomphe de Comte*, *Reine de Danemark*, *Comtesse de Maille*, *John Laing* (ever a distinct and desirable *Caladium*), *Duchess of Teck* (a pale-leaved sort, that was a pleasant relief to the highly-coloured pieces); a fine plant of *Madame J. Box* looked handsome, also *Baron Adolphe de Rothschild*, *Princess Royal*, *Icarus*, *John Peed*, *Charlemagne*, *Henry Dixon*, *Silver Cloud* (very pretty), *Comte de Germiny*, *Sir Henry Irving*, *Sir W. Harcourt*, *Mr. W. H. Cummins*, and *Ibis Rose*, pretty plants of this last very desirable variety. The face of the group consisted of lesser plants of greater novelty. One of the most striking of these quite new was named *W. E. Gladstone*. This has leaves with very bright-coloured veins suffusing part of the lamina, and the margins are green; *Le Nain Rouge*, a self-coloured leaf of some depth; *H. J. Chapman*, a very delicate-looking plant, with pinkish coloured leaves, and deeper veins. This plant had been much damaged by exposure, otherwise we think it might have presented a fine appearance; and *Charlotte Hoffman*, nearly pure white, very dwarf.

Messrs. JNO. LAING & SON, Forest Hill Nurseries, London, S.E., whose *Caladiums* have generally been a feature of the Temple Show, again made a fine display of these lovely plants on the present occasion. Divided only from Messrs. Peed's group of similar plants by a group of flowering plants, those from Messrs. Laing at once strike the visitor (especially if that visitor be a connoisseur) that the many good things in the group would have been of greater individual effect had more space been given to the plants. Beyond this, however, the picture the group presented was one of infinite variety of tint, and the cultivation was remarkable in the high colours to be seen in those varieties that are noted for this characteristic, and for the robustly healthy appearance of the plants generally. Such varieties as *Flammant Rose*, *Alfatre*, *Triomphe de Comte*, *John Laing*, *Flambeau*, *Madame Mitjana*, *Baron de Mamore*, *Rose Laing*, *W. Marshall*, *Baron Adolphe de Rothschild*, and other specimens as large were faced by equally pretty, though smaller plants, some of which were novelties. Of the novelties, an Award of Merit was recommended to *Guaratuguet*, a highly-coloured shade of crimson leaf, with prominent veining, and pretty broken margin of green. Other novelties were *Garten inspektor Siebitt* and *Jaquary*, a round with pea-green margins and coloured heart. Other small plants of lesser novelty, but of equal attractiveness, increased the beauty of the group.

The group of *Caladiums* from Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, was better than anything of the same nature we have previously observed from this well-known establishment. In the centre of the back row was a gigantic plant of *Madame John Box*, one of the finest plants ever exhibited. Its effect was glorious; whilst on one side of it was placed a plant of *George Berger*, in which the colour was unusually good; *Baron Adolphe Rothschild*, candidum, *Gaspard Crayer*, *Sir Henry Irving*, and a fine plant of *Mrs. Harry Veitch* completed the back row. In front were capital specimens of *Mme. E. Pynaert*, *Lord Derby*, *Mme. Groult*, *Williamsii*, *Louis Van Houtte*, *Raymond Lemoine* (a most bizarre-looking variety, but very attractive), *Triomphe de Comte*, with magnificent colour, *Silver Cloud* (a beautiful variety of last year); *Rose Laing*, *Ignate*, *Martha Laforge*, *Sir Julian Goldsmid*, *Comte de Germiny*, and *Duchess de Montemart*, all these were beautiful, and grouped thinly in frames of fern, that all and each could be conveniently seen and admired. The front row consisted of perfectly or comparatively new varieties. *Lady Mosley* and *Sir Stafford Northcote* we saw last year, but the latter especially was more magnificent now, and may be noted as a first-rate and striking novelty. The *Mikado*, *Jno. Luther*, and *Edith Luther*, are quite new, and of these we think *Jno. Luther* will prove much the best; and it possesses a new tint in *Caladiums*.

Messrs. F. SANDER & CO., St. Albans, obtained an Award of Merit for *Caladium Ami Schwartz*, a seedling from *C. albanense* (shown by this firm last Temple Show, and illustrated in these pages), and *C. Madame J. Box*. The seedling is a pretty plant, with deep red shield-shaped leaves, margined green.

BEGONIAS.

The tuberous-rooted *Begonias* were distributed in several tents. Those in tent No. 4, with the magnificent *Calceolarias* from Messrs. JAMES & SON, and *Cannas* from Messrs. H. CANNELL & SONS, created an enormous blaze of colour. Indeed, in this tent generally the wealth of flowers was extremely lavish.

Mr. H. J. JONES, of the Ryecroft Nurseries, Lewisham, covered his allotted space of 100 square feet with closely-packed plants of single and double-flowered varieties, pro-

miscuously mixed one with the other. Few of them were named, but the strain was a proved good one, by the bright large flowers, which were of much substance, and the large number of them on the plants. *Dorothy Linford* and *Edie Wright* are novelties, each of which is bi-coloured, has a white centre, and is very pretty.

A group of *Begonias* from Mr. J. R. Box, West Wickham and Croydon, was very gay. The double-flowered varieties were placed in the centre, with single flowers on either side of them. The plants were prettily interspersed with *Adiantum* Ferns, and they were of capital quality, whether single or double-flowered. Of doubles, we noticed *Zelinda*, a beautiful cherry-red flower; *Hogarth*, semi-double, large flower, bright and vivid scarlet; *Miss Lennard*, very delicate flower, pale lemon-coloured, about 3 inches broad and 2 inches deep; *Harmony*, a prettily-tinted salmon-pink-coloured flower, of large size and good form; *White Lady*; *Defiance*, a scarlet-crimson; *Orient*, scarlet-crimson; *Eureka*, white; *Opal*, a fine salmon-pink. Of single-flowered the whites and yellows were extremely fine. *Belona* (white), *Zenobia* (yellow), *Canary* (yellow), and *Hecla* (a very fine deep rose-coloured, widely-expanded flower) were noticed. *Proserpine* is a smart-looking cerise-coloured variety.

Messrs. CANNELL & SONS, Swanley, made a somewhat smaller exhibit of *Begonias* than usual, but in a small area; a selection of single and double-flowered varieties was put up, that went to maintain the high position Messrs. Cannell have attained in relation to the cultivation of these plants. *Lord Rothschild* was an exceedingly bright double and *Miss A. Stewart*, a large yellow single-flowered variety.

Mr. THOS. S. WARE, Hale Farm Nurseries, Tottenham, had a narrow bank of *Begonias* in Tent No. 3, and the plants made a glorious display. Both single and double-flowered varieties were exquisite, all of the plants being exceedingly well-flowered, whilst the blooms themselves were of fine size and substance and brilliant colouring.

Of novelties a very beautiful apricot-yellow, double-flowered variety named *Mr. Dunbar Wood*, was recommended an Award of Merit. Some of the best scarlet doubles were *Mr. Jas. Portbury*, *Brilliant*, *Mrs. Arthur Pitts*, *Mr. John Fowler*. *Maid of Kent* is a marvelously pretty pink variety; *Princess of Wales*, a white flower tinted and edged pink, one of the prettiest doubles; *Mrs. S. Pope* (a capital white), *Jubilee Beauty* (scarlet with white centre), *Miss Jennie Fell* is a capital scarlet double of the very brightest tint; *Her Majesty* (white), *Miss Fanny Joseph* (pink), *Beauty of Besley* (coral colour), *Beauty of Belgrove* (pink), and *Duchess of Devonshire*. All of the above are good doubles, and these were much more numerous in the group than were singles.

Messrs. JNO. LAING & SONS' *Begonias* from the Forest Hill Nurseries were grouped upon the central stage in Tent No. 3. Between a group of *Gloxinias* and the fine Ferns from Mr. H. B. MAY, the brightly-coloured flowers made a grand show. The single-flowered and double-flowered sorts were grouped by themselves, and each was good. Of singles, *Miss Alice de Rothschild*, yellow; *Mrs. Davis*, richer, and bronzy-yellow; *Mrs. J. Pierregont Morgan*, primrose-yellow; *Lord Chas. Beresford*, scarlet, were capital. Of doubles, *Lady Tweedmouth*, *Countess of Dartmouth*, white; *Lady Powerscourt*, pink; *Duke of Eife*, *Lady Gifford*, and *Lady Chas. Beresford* were equally commendable.

FERNS.

The exhibits of Ferns were of more interest than usual, but the space available for the display of such plants is unfortunately too limited for very large specimens, or for noble tree-ferns, that have so decided an effect in a large exhibition.

Messrs. W. & J. BIRKENHEAD, Fern Nurseries, Sale, near Manchester, as usual made an exhibit of very choice varieties. They clothed the end of the central table in No. 3 tent. In the first place, a glass-case of considerable size provided a suitable protection for a collection of filmy Ferns, and amongst these we noticed pretty specimens of *Todea superba*, *Hymenophyllum crispatum*, *H. Fosterianum*, *Trichomanes angustatum*, *T. maximum umbrosum*, *T. radicans Andrewsii*, *T. radicans cambricum*, *T. venosum*, *T. Colensoi*, &c. Amongst the less tender species, we noticed *Davallia fijiensis elegans*, *D. f. major*, *D. Mooreana*, a very pretty plant, *D. tenuifolia stricta*, with beautiful feathery, but erect fronds, and *D. tenuifolia Veitchiana*, *Gymnogramma Dobraydensis*, a rather loose habited, gold-powdered variety; *G. Lauchiana*, *G. peruviana argyrophylla*, *G. Alstoni*, and *G. schizophylla gloriosa*, an exceedingly pretty but green *Gymnogramma*. Of *Adiantums* there were *A. macrophyllum*, *A. Lawsonianum*, *A. Collisii*, and *A. rubellum*, with prettily tinted fronds, and one of the best gems in the group. The *Athyriums* were represented by a few fairly-sized plants: *A. f. plumosum elegans*, *A. f. plumosum superbum grandiceps*, *Polystichum ang.*, in very numerous varieties, *Polypodium*, *Pteris*, *Selaginellas*, and other genera were all included in variety; *Polystichum angulare divisilobum plumosissimum*, fairly described by this rather long name, was one of the most beautiful plants in this exhibit.

A small group of plants of *Lastrea fragrans*, surrounded with cork, attracted attention as the violet-scented Fern, but this feature was rather difficult of appreciation.

Mr. H. B. MAY, of Dyson's Lane Nurseries, Upper Edmonton, had the most imposing group of Ferns in the exhibition, the plants being generally of considerable size, and inclusive of a large number of novelties. The gem of these—indeed, one of the most remarkable novelties at the Temple other than those previously seen at Ghent, and which was awarded a First-class Certificate, was *Phlebodium glaucum Mayii*, fig. 121 of the Supplement to our present issue. As

will be seen from the photograph, the outline of the fronds is altogether different than anything previously seen in varieties of this group. It would seem to come nearest to *P. glaucum*, and, in fact, the plant appeared amongst seedlings of *glaucum*, but the margins of every frond are serrated, notched irregularly, and frilled to such an extent that the place of the somewhat flat appearance of the type, the plant is a beautiful picture of wavy, broken outline. Then the veining of the fronds is peculiarly distinct, for in addition to the primary veins nearly all the subsidiary ones are distinctly visible. Two primary veins run parallel with the mid-rib of the leaf, and very fine ones from these in a kind of net-fashion from those to the margin of the frond. The veins are purple or violet in tint, and the fronds generally possess a silvery metallic lustre, which is one of the charms of the plant. The plant, which was shown under a glass case, is hardly six months old, and being a good grower the variety will probably exceed in height and vigour that of *P. glaucum*. It must be remembered that botanically all the *Phlebodiums* are now included under *Polypodium*. *Adiantum Hemsleyanum* (fig. 124) is another plant shown by Mr. H. B. MAY, and requires little description here, as its characteristics are well shown in the photograph. The peculiar shape of the pinnae give the variety an unusual light and "starry" appearance. It was distinguished by a First-class Certificate of the Royal Horticultural Society in 1894, but it was found exceedingly difficult to increase the stock. *Davallia fijiensis effusa* (fig. 118) is a robust growing variety of this species. It is more spreading than the type, and is expected to produce fronds 5 feet length.

Other novelties in Mr. MAY's collection included *Pteris cretica Summersii*, a very much crested cretica, being an improvement upon *Wimsettii* exhibited a month ago at the Drill Hall, when an Award of Merit was obtained; *Gymnogramma chrysophylla grandiceps superbum*, being real super improvement upon *G. c. grandiceps*, and awarded First-class Certificate at the Fern conference at Chiswick. It is still a novelty, however, owing to the failure for some time of the efforts to propagate the variety. *Pteris serrulata gracilis multiiceps*, a very slender-habited plant, but heavily crested.

A collection of Ferns from Messrs. J. HILL & SON, Lower Edmonton, staged in No. 4 Tent, included a considerable variety and well-cultivated specimens. *Davallia fijiensis plumosa*, *Asplenium nidus Avis*, *A. caudatum*, *Adiantum formosum*, *A. gracillimum*, and *Pteris tremula Smithiana* in large specimens, some of which were suspended, helped to give an effective background to the exhibit. Toward the face were many of the choicer forms, and some of these were grouped together in baskets, of which *Adiantum scutum roseum*, *A. macrophyllum*, and other prettily-tinted varieties were noticeable. For the rest, many of the popular genera were represented in attractive forms.

MISCELLANEOUS EXHIBITS.

AMARYLLIS.

These were sparingly represented, and were it not that Messrs. KELWAY & SON, of the Langport Nurseries, had brought some cut specimens, with which they formed two panels to their stand of cut-flowers, they would not have been represented. Messrs. KELWAY & SON claimed to have produced a race of hardier forms of *Amaryllis* than is usually grown, and thus some lateness in flowering may be accounted for.

CALCEOLARIA.

were numerous, and generally fresh and good, dwarf in growth, and profuse in bloom. Messrs. J. JAMES & SON, Woodside, Farnham Common, Bucks, staged a collection of about fifty plants remarkable for their dwarf growth, the size of their blooms, and their brilliant colours. Collections of *Calceolarias*, as a rule, show a preponderance of yellow in their colouring, and there is a general tendency to hark back to it. But few yellow tints were in the Woodside collection; some with buff and salmon grounds were handsomely maculated, and there was to be seen a white variety. The size to which the individual blooms has been brought is shown by the fact that one of the blossoms measured 2½ inches in length. This collection was set up with a line of Palms at the back, with dwarf Ferns interspersed, and forming a front edging.

Messrs. H. CANNELL & SONS had a collection of two dozen plants, similarly mingled with Palms and Ferns. The plants forming this collection were of dwarf growth, and a little freer in habit than the preceding collection; some of the crimson shades were very bright, and one of a crimson-maroon shade was very fine. The front line was formed of *Echeveria farinosa*, and small Ferns.

Messrs. JAMES CARTER & CO., seed merchants, Holborn, had a collection of some 150 plants, filling a considerable space of tabling, dwarf in growth, varied in colour, and the blooms of fine quality. The tall *Calceolarias* of thirty or forty years ago appear to have disappeared from cultivation.

GLOXINIAS.

were very bright and effective. A collection from Messrs. H. CANNELL & SONS, set up in the same way as their *Calceolarias*, was smaller in the flower than is usually seen, but they represented a varied strain, remarkable for their quality of bloom. As it appears customary still to name *Gloxinias*, a few of the leading varieties in this collection were *White Queen*, *Prince of Wales*, pale crimson; *Princess of Wales*, pale bright crimson, margined white; *Duchess of York*, white, with a narrow waved line of pale rose; and *Nestor*, dark purple.

Messrs. J. LAING & SONS, Stanstead Nurseries, Forest Hill, had a collection of some thirty plants, finely bloomed, varied in colour, with large bold flowers.

Messrs. J. PEED & SONS, nurserymen, Lower Norwood had a collection of some 100 plants admirably set up, and which formed a commanding feature in the tent; some of the varieties were particularly fine and distinct, such as Beacon, Duke of York, Exquisite, charmingly maculated; John Peed, Duchess of York, Minnie Peed, Princess of Wales, a very distinct variety, densely spotted with dots of purple, and edged with white; Mrs. W. Weaver, &c.

Messrs. A. W. YOUNG & CO., nurserymen, Stevenage, staged a small collection with other things.

A large and striking collection of some 100 plants was staged by Messrs. JAMES VEITCH & SONS, which included many good varieties, chief among them Monarch, La Belle, white; Irene, Achille, Oberon, Cicely, Seraph, Argus, Electra, Virginale, Modesty, Mars, very bright; and Columbus.

The ANGLO-CONTINENTAL GUANO CO., had a small table of Gloxinias, presumably grown with their manures

CARNATIONS

were in good force, and were contributed by several exhibitors.

Mr. C. TURNER, Slough, had a panel of well-flowered plants

of Wales, plants probably three years old, grandly grown and bloomed.

Messrs. DICKSONS, LTD., Chester, had a group of the yellow Carnation, Duchess Consuelo which was raised at Blenheim, and may be regarded as a yellow Malmaison, and a fine addition to the section.

Mr. FREDERICK PERKINS, Regent Street, Leamington, had a number of plants of a pale yellow Carnation named Primrose Queen, nicely arranged with Ferns. It is a free blooming variety of good quality.

PELARGONIUMS

were sparingly shown: Mr. C. TURNER had a few large specimens of show varieties freely bloomed, such as Joe, Mystery, Prince Leopold, Alice, a pretty light variety, Spotted Beauty, Maid of Honour, St. Blaise, brilliant crimson, Maggie, Lady Isabel, of a mauve-pink tint, distinct; Edward Perkins, and Marguerite, a charming pale flower; also freely-bloomed specimens of the following fancies, The Shah, Iona, and Princess Teck.

PEONIES

were not shown in their usual good character, the forms of *P. arborea* formed the great bulk of them, and they had been forced into bloom.

Messrs. KELWAY & SON, Langport, were the only exhibitors

varieties of Orchis, *Primula*, *Sicboldi* in variety, a deep coloured one named *Tragedia* being very striking; *Eremurus himalaica*, Geums in variety, *Heuchera sanguinea*, *Pæonies*, Tulips in variety, Iris in great variety, Oriental Poppies, *Adonis pyrenaica*, *Anemones*, *Lilium Harrisii*, Early Gladioli &c.

Mr. M. PRITCHARD, nurseryman, Christchurch, had a nice select collection, consisting of Geums in variety, *Camassia esculenta*, *Trollius* in variety, *Aquilegia*, *Saxifraga granulata* fl.-pl., a plant which deserves to be much more grown; *Campanula Balchiniana*, Iris in variety, *Eremurus Elwesianus*, *Delphinium nudicaule*, *Trillium stylosum*, *Cytisus purpureus* var. *incarnata*, *Primula japonica*, &c.

Mr. T. S. WARE, Hale Farm Nurseries, Tottenham, had an interesting collection which included *Liliums*, Iris in variety, *Iberis gibraltarica*, Geums in variety, Tulips, *Lupinus polyphyllus*, *Delphinium nudicaule*, *Anemone narcissiflora*, *Cypripedium calceolus*, *Heuchera sanguinea*, *Eremurus Elwesianus*, a very fine spike (Award of Merit), *Spiraea chinensis*, which again failed to obtain an award; *Ranondia pyrenaica*, *Trillium grandiflorum*, *Darlingtonia grandiflora*, &c.

Mr. AMOS PERRY, nurseryman, Winchmore Hill, also had a select collection, which comprised a pleasing variegated form of *Cheiranthus alpinus*, *Trollius*, Orange Globe, very fine; various forms of Tulips, *Camassia Leichtlini*, *Campanulas*, *Aquilegia Stuarti*, *Arenaria grandiflora*; a fine form of *Papaver orientale*, the large, pale, orange-red flowers flaked with a pale creamy colour; *Polemonium Richardsoni*, &c.

Messrs. A. W. YOUNG & CO. had a group comprising Lilies, *Aquilegia*, Iris, *Papaver nudicaule*, *Phlox subulata*, *Linum narbonense*, *Trollius*, Tulips, &c.

An extremely interesting collection was staged by Messrs. R. WALLACE & CO., Colchester, which formed a big exhibition of itself, as it comprised many subjects of which they were the sole exhibitors, such as *Lilium Hansonii*, *Calochorti* in variety, which included some beautiful species and varieties; *Ixias* and *Sparaxis* in variety, varieties of *Lilium Thunbergianum* and *umbellatum*, *Incarvillea Delevayi*, a batch of *Watsonia O'Brienii*, *Lilium rubellum*, fig. 128, p. 335, a distinct new species elsewhere described; hardy *Cypripediums* in variety, *Ornithogalum arabicum*, *Tritonias*, various forms of new Iris, &c.

Messrs. JACKMAN & SON, W. King, had a small collection of hardy flowers, including *Pæonies*, *Trollius*, *Pyrethrums*, Iceland Poppies, pans of *Cheiranthus alpinus* and *Marshalli*; *Spiraea astilboides*, *Lychnis Haageana*, *Thermopsis montana*, &c.

Messrs. CARTER & CO. had late Tulips in variety, *Anemones*, Iris, early Gladioli, *Narcissus*, the deep yellow *Ranunculus Seraphique*, &c.

Messrs. CHEAL & SONS, Lowfield Nurseries, Crawley, set up a bank of hardy flowers, which included boards and sprays of Violas, the very distinct Iona being particularly noticeable; *Lupinus polyphyllus* in variety; *Pyrethrums*, *Rhododendrons*, Oriental Poppies, &c.; and a design of a bank in a garden, planted with choice alpine, &c., a very pleasing feature.

PANSIES AND VIOLAS.

These came from several exhibitors: Messrs. ISAAC HOUSE & SON, florists, Westbury-on-Trym, had a stand of bunches of fancy Pansies and Violas, boards of the former, some of them very fine, and baskets of Violas in small pots, chief among them Prince of Wales, yellow; Stophill Gem, maroon and crimson, bordered with white; White Empress, very pure; A. J. Rowberry, &c.

Mr. WILLIAM SYDENHAM, florist, Tamworth, had a collection of sprays of Violas, including Mrs. Crane, purple maroon, with white top petals; Masterpiece, William Tell, and Blanche, white; Pembroke, yellow; Alexander, pale silvery-claret; and also a series of devices worked with Viola blooms, which did not tend to present the Viola to view as a decorative agent.

Messrs. F. MILLER & CO., Florists, Fulham Road, S.W., also had a collection of bright fancy Pansies, *Petunias* were shown by them, a good bedding strain; and Messrs. CARTER & CO., also had groups of these plants in their collection.

AURICULAS,

in the form of some new alpine varieties, came from Mr. J. DOUGLAS, Great Bookham, Surrey; chief among them were several plants of Dean Hole, a very fine and striking variety; Delphi was the best of the new alpine varieties submitted for Certificates. A new green-edged variety, named Tric Frog, appeared to be, as shown, inferior to Mrs. Henwood or Abbé Liszt.

Mr. R. DEAN, Ranelagh Road, Ealing, had double-flowered Auricula, Snowdrop, a white variety carrying a large truss of white flowers, and quite unique in its way (Award of Merit).

SWEET PEAS.

A collection of some fifty bunches of Sweet Peas came from Mr. F. G. FOSTER, Brockhampton Nurseries, Havant, which had been forced into bloom; they formed a pleasing feature.

FLORISTS' TULIPS.

A collection of these was staged by Mr. GEO. EDUM, Walton-on-Hill, Essex. The flowers, which were of good size, comprised some bright breeders; such as *bizarres* as Samuel Barlow and Lord F. Cavendish; *hyblæmens* *Adonis*, Duchess of Sutherland, and Mrs. Mills; roses, Mrs. Lea, Mrs. Collier, and Annie McGregor.

FIG. 127.—GROUP OF FRUIT TREES IN POTS.

(Grown by Mr. J. Hudson, Gardener, Gunnersbury House, Acton. See Report of Temple Show.)

on either side of his Roses, together about 100 specimens, chief among them Queen of Fancies, an improved stadtrath Bail, with more colouring in it, which richly deserved the Awards of Merit the Floral Committee refused to give it; Juliana, a rose edged Picotee; The Gift, Little John, Sir Guy, May Queen, Primrose League, Snowdrop, Helios, and Knight Errant.

Messrs. W. CUTBUSH & SON, Highgate Nurseries, had a large corner group of flowering-plants in the large tent, the ground-work Malmaison Carnations; among them were two new varieties of decided promise, viz., President McKinley, buff, with a slight salmon centre, quite distinct in colour, and Madame Adelina Patti, pink, deepening to salmon, with faint rose stripes on some of the petals; the flowers were large, full, and of fine shape. In addition, they had two groups of Carnations, chief among them Queen of the Buffs, distinct in tint, and fine in petal; Miss Audrey Campbell, yellow; Waterwitch, The Gift, Duchess of Fife, delicate pink, very pleasing; La Villette, pale rose flushed with delicate violet; Germania, very fine; and Princess May, bright rosy scarlet.

From Mr. Jennings, gr. to LEOPOLD DE ROTHSCHILD, Esq., Ascott, Leighton Buzzard, came a group of some sixty plants of a rose-coloured variety of Malmaison, known as Princess

of a collection in pots, chief among them Agnes Mary Kelway, cream and pink; Cassius, pale rose; Lady Beresford, pale pink; Duchess of Teck; Diadem, single rose, &c. And in a collection of cut flowers were Julius Caesar, rich crimson, very fine (Award of Merit); The Bride, white; Henry Irving, chestnut-crimson, very fine in colour (Award of Merit); Cicero, pale rosy-pink; Jean de Resky, a very fine white, broad in the petal, and quite pure (Award of Merit); and a number of varieties unnamed.

Captain TORRENS, Hayes, Kent, had a bloom each of four varieties, imported from Japan, all of a decidedly promising character.

HARDY PLANTS,

herbaceous and otherwise, were as usual shown in quantities, and some of them might have been left out with advantage, for only the best things should find a place in such an exhibition.

Messrs. BARR & SON, King Street, Covent Garden, had a large and varied collection. There were seen *Delphinium nudicaule*, *Cyclamen repandum*, hardy Ladies' Slippers in variety, *Cytisus* in variety, including bushes of *Andreanus* and *C. hispanica pumila*, *Trollius* in variety, Orange Globe being especially noticeable; *Gentiana verna*, *Erigeron Roylei*, *Primula japonica*, varieties of *Phlox subulata*,

ORCHIDS.

A grand display of Orchids was staged in the great marquee, and in the long tent adjoining.

As usual, the President of the Society, Sir TREVOR LAWRENCE, Bart., filled the place of honour as the largest and best exhibitor, the space with a frontage of twenty-five feet in the entrance of the tent occupied by his group, being in itself well worth a journey to see. In the staging of the group too, Mr. H. WHITE, his orchid grower had displayed great skill, and brought out well the main features of the plants staged. The centre was occupied by a fine example of *Cymbidium Lowianum*, and arranged along the back and in the body of the group was a very fine and varied selection of varieties of *Laelia purpurata*, *Cattleya Mossiae*, *C. Mendeli*, *C. Lawrenceana*, *Miltunia vexillaria*, some noble *Odontoglossum crispum*, and other showy species of albinos. Several of the species were represented in the group, and prominent among them were *Cattleya Mossiae* Wageri, *C. Skinneri* alba, *Sobralia macrantha* alba, *Dendrobium Parishii* albens, and *Epidendrum* \times *elegantulum* *leucochilum*. Gracefully arching over the group were the elegant sprays of the slender-stemmed *Epidendrum*, *Dendrobiums*, *Oncidiums*, &c., remarkably effective being *Epidendrum Randii*, *E. x O'Brienianum*, *E. x elegantulum*, *E. Wallisii*, the dark scarlet *E. Schomburgkii*, the purple-lipped *E. Mooreanum*, *Schomburgkia tibicinis*, and the curious *Dendrobium O'Brienianum* striatum with its pendulous racemes of whitish flowers striped with purple. Among other good things noted were a fine specimen of *Epiphronitis x Veitchii*, one of the most brilliant of hybrids, a good example of *Cymbidium tigrinum*, a fine specimen of *Colax jugosus*, *Cattleya x Parthenia*, floriferous plants of *Masdevallia rosea* *M. ignea*, and other *Masdevallias*; and among the many fine *Cypripediums*, no less remarkable for their handsome and healthy foliage than for their beautiful flowers, the noble *C. x Olenus* Burford variety, the largest and most richly coloured of its class with a fine twin flowered inflorescence. Raised on a stage in the centre of the group was a batch of the rare and pretty species for which the great Burford collection is noted, and among them were the bright scarlet-crimson *Renanthera imschootiana*; the blue *Dendrobium Victoria Regina*, the paler blue *Aganisia corulea*, the dwarf white and violet *Epidendrum Endresii*, and its hybrid *E. x Endresio-Wallisii*; the curious little *Polystachya bulbophylloides*, a very frail plant, but notwithstanding that, like so many other little gems, it has been retained in vigour for many years at Burford.

Among the *Masdevallias* were the pretty *M. Arminii*, *M. pachyura*, *M. caudata* *xanthocorys*, and *M. O'Brieniana*; and also represented were the carmine-red *Habenaria rhodochela*, the orange-scarlet *Saccolabium miniatum*, and a fine pan of *Macodes petola*, and *Dendrobium Hughii*.

The next group, both in succession and importance, was that from SIR FREDERICK WIGAN, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), and it also was well staged. In it as in most of the other large groups *Laelia purpurata*, and *Cymbidium Lowianum*, on account of their size, figured conspicuously in the background, the varieties shown of each being of the best. *Cattleya Mossiae*, *C. Mendeli*, *C. Skinneri*, *C. Skinneri* alba, *C. intermedia* *Parthenia*, and *C. Lawrenceana*, were very showy, and in the centre were the rare *Cypripedium callosum* *Sanderæ*, *C. bellatulum* *album*, *Miltunia vexillaria* *Chelseiensis* with fine purple marking in the centre; and among the *Odontoglossums*, some fine *O. crispum*, *O. citrosum* *punctatissimum*, &c.; other remarkable plants were a very fine specimen of *Cypripedium caudatum*, *Disa Veitchii*, *Epidendrum hastatum*, the pigmy *Eria extensoria* with several sprays of its neat little flowers, *Cypripedium x Kerchovianum*, *W. H. Young* (*barbatum* var. \times *Curtisii*), and *Dendrobium Victoria Regina*.

The Rt. Hon. EARL PECCY, Lion House, Brentford (gr., Mr. G. Wythes), staged a very fine group in which the best old favourite Orchids were finely shown. Among the many fine specimens of *Cattleya Mossiae*, *Laelia purpurata*, *Cymbidium Lowianum*, &c., were well-grown examples of *Vanda teres*, a fine *Coelogyne Dayana*, good specimens of *Oncidium Marshallianum*, *Thunia Marshalliana*, *Dendrobium thyrsiflorum*, and *D. Gibsoni*; good *Odontoglossum crispum*, *O. Pescatorei*, *O. triumphans*, *Miltunia vexillaria*, and representatives of many of the other showy species of the season.

Next came a pretty little group of *Cattleyas*, *Odontoglossums*, *Laelias*, &c., staged by MALCOLM S. COOK, Esq., Kingston Hill; and then followed a very fine assortment staged by Mr. JAS. CYPHER, of Cheltenham, with his usual skill. In it the varieties of *Laelia purpurata* were very fine, and varying from the white-petalled to the very dark-coloured forms. Here and there above the rest of the plants were elevated some finely-flowered *Cattleya citrina*, and throughout the group were elegant plants of *Oncidium Marshallianum*, good varieties of *Odontoglossum crispum*, a finely spotted *O. nebulosum*, *Cattleya Lawrenceana*, *C. Schilleriana*, *C. Skinneri* and other *Cattleyas*, good *Dendrobium Dearei*, *Epidendrum x O'Brienianum*, *Mormodes citrinum*, *Masdevallia rosea*, *M. Schlunzi*, *Anguloa Clowesii*, *Oncidium olivaceum* *Lawrenceanum*, some elegant *Thunias*, &c.

MESSRS. F. SANDER & CO., St. Albans, occupied both sides of the end of the central stage with a very remarkable collection replete with good things. In it the *Odontoglossums* were very fine, and especially the varieties of *O. luteo-purpureum*; the varieties of *O. crispum* too were remarkable by their large and finely-formed flowers. Among the more remarkable of the exhibits in this group were *Cypripedium callosum* *Sanderæ*, *C. bellatulum* *album*, *C. x macrochilum* *giganteum*, *C. Sanderianum*, *C. x conco-bellatulum*; *C. x Doncasterianum* *inversum*. Among the *Odontoglossums* were several very fine blotched forms of distinct features, one of them

being a pretty variety of *O. Adrianae*. Other specially noteworthy plants in this group were a fine *Oncidium sarcodes* with many branched spike; *Cattleya Mossiae* *Victoria*, with yellow lip freckled with rose colour; some good *C. M. Wagneri*, and *C. M. Reinckiana*; *Cattleya Skinneri* *alba*, *Masdevallia Veitchii* *grandiflora*; *Sobralia macrantha* *alba*, grand specimens of *Oncidium ampliatum* *majus*, &c.

H. S. LEON, Esq., Bletchley Park, Bletchley (gr., Mr. A. Hislop), followed with a very bright and effective group containing many good and rare things, the *Cattleya Skinneri*, *C. Schroderæ*, *C. Lawrenceana*, *C. Mendeli* and *C. Mossiae*, being specially fine. In the centre of the group, a specimen of *Cattleya Luddemanniana* *Ernsti*, with gigantic rose and purple flowers, was a striking object; and in the group the scarlet *Epidendrum radicans*, some fine *Odontoglossums*, *Calanthe veratrifolia*, *Vanda tricolor*, *V. suavis*, var. *teres*, *Dendrobium nobile* *Bletchley Park* variety; *D. n. nobilius*, *D. infundibulum*, and some excellent *Oncidium concolor*, of which the large-flowered *O. c. superbians* was the best, were attractive features.

MESSRS. CHARLES WORTH & CO., Heaton, Bradford, staged not only one of the best and most extensive collections, but also one of the most interesting, by reason of the many hybrid novelties it contained. So numerous were the entries to go before the Orchid Committee, that it is only possible to touch on a portion of the good things shown. The result in Awards will be seen in the appended list. *Cattleya x Fernand Denis* (*Acklandiae x Warscewiczii*) was one of the best things shown, the habit of the plant being like a gigantic *C. Acklandiae*, the large waxlike flower of a bluish-white, with rose-coloured freckling on the sepals, the broad wavy front lobe of the help being rose crimson—a very distinct hybrid.

Another superb new hybrid was *Laelio-Cattleya x Admiral Dewey* (*C. Warneri formosa x L. elegans*), a large flower with pale rose sepals and petals, the showy front of the lip being rose-purple, and both these secured First-Class Awards.

Another interesting hybrid was *Laelio-Cattleya x Schilleriana*, home-raised between *L. purpurata* and *C. intermedia*, and which proves another conjectured parentage adjudged to the imported plant; and very pretty were *Laelia x cinnabrosa* (*cinnabarina x tenebrosa*), *Epi-Laelia x Charlesworthi* (*L. cinnabarina x E. radicans*); *Laelio-Cattleya x intermedia-flava* ("Golden Queen," with bright yellow segments; *L. C. x radiata* (*L. purpurata x C. dolosa*), *Cattleya x Breataeana* (*Loddigesii x superba*); also *Odontoglossum cordatum* ("Charlesworth's variety," a very dark-coloured form; *O. sceptrura* *leucoglossum*, *O. Halli*, "Charlesworth's variety," *O. crispum* *Jeanette*, and other very handsome forms of *O. crispum*; *O. nelulosum* *punctatissimum*; *Cypripedium x Schofieldianum* (*bellatulum x hirsutissimum*), &c.; and among other good things in the group were three plants of *Cattleya Mossiae* *Reinckiana*; a good form of *Odontoglossum Uro-Skinneri*, *Masdevallia Veitchiana*, *Cochlidoda Noezliana*, *Cymbidium tigrinum*, &c.

MESSRS. B. S. WILLIAMS & SON, Victoria and Paradise Nurseries, Upper Holloway, staged a fine group, in the back of which were good specimens of *Vanda tricolor* and *V. suavis*, for which the firm is noted. In the group also were exceptionally good varieties of the showy *Odontoglossums*; the pretty hybrid *Laelio-Cattleya x intermedia-flava*; some fine *Laelia purpurata*, *Aëridea Houletianum*, *Laelia x Latona*, *Calanthe Williamsii*, *Thunia Bensoniae*, *Pescatorea Lehmannii*, &c.

W. THOMPSON, Esq., Walton Grange, Stone, Staffordshire (gr., Mr. W. Stevens), staged a charming little group of grand varieties of *Odontoglossums*, among which were *O. crispum* *Lily*, rose-tinted and profusely spotted with red, especially on the petals; *O. c. Capartianum*, a fine flower with conspicuous spotting; *O. c. Thompsonianum*, one of the very finest of blotched *crispums*; *O. c. Dorothy*, with large purplish markings; *O. Wilckeanum* *grande*; a fine *O. tripudians*; a beautifully spotted hybrid of the *O. Rochfordianum* class; *O. x excellens* var., a large sparsely-spotted yellow-form; and other fine things marvellously well-grown.

LUDWIG MOND, Esq., showed a neat group of *Odontoglossums*, *Cattleyas*, &c.; Messrs. HUGH LOW & CO., Bush Hill Nurseries, Enfield, staged a grand assortment, in which the forms of *Cattleya Mendeli* were superb, two of them, viz., *C. M. Oakes Ames*, a noble flower with large bluish-white flowers bearing a showy crimson feather on the petals, and glowing ruby-crimson lip; and *C. M. Mrs. E. V. Low*, a charming flower of superb form and delicate tint, were among the best and most distinct of the species in the show. Also very beautiful in Messrs. Low's group were *Odontoglossum crispum* *Memoir* *W. E. Gladstone*, a fine rose-tinted and heavily-blotched flower; *O. c. Dieudonné*, a neat pure white, with pretty purplish spots; *Dendrobium Dalhousieanum* *salmoneum*, a remarkable variety, in which the dark blotches usually seen on the lip were almost obliterated. *Laelio-Cattleya x Schilleriana* *Lowiae*, a large richly-coloured flower; *Cattleya Mossiae* *Wagneri*, and *C. M. Reinckianum*, the singular *Bulbophyllum Claptonense*, *Oncidium tetracopis*, &c.

In the adjoining long tent MESSRS. LINDEN, l'Horticulture Internationale, Park Leopold, Brussels, staged a grand group of *Odontoglossums*, running a considerable distance up the side-stage, and affording an admirable object-lesson, illustrating the extraordinary variety obtainable from a very few species, for notwithstanding the fact that but few species were represented, there were no two plants exactly alike, the form or the colour, or disposal of the markings, differing widely in each from any other. Among the more striking were *Odontoglossum x Adrianae* *venustum*, a crisped and profusely-spotted

O. Hunnewellianum *hybrid*; *O. Pescatorei* *bellatulum*, with remarkable triangular purple markings; *O. x cirrhosum* *Halli*, yellow, spotted brown; *O. Hunnewellianum* *superbum*, a very pretty flower; *O. crispum* *jaspeum*, a showy rose-tinted bloom; *O. x Wilckeanum* *rufidum*, with reddish rose-tinted bloom; *O. W. brunneum*, with chestnut-brown blotches; *O. crispum* *rubellum*, tinged and spotted purple of the Franz Masereel class; *O. vexillarium* *Moortbeekense* with very large flowers. *O. polyanthum* *expansum*, large and richly coloured; *O. crispum* *zebrinum*, barred with purplish-brown; *Cattleya Mossiae* *Marguerites* and at one end of the group a grand batch of varieties of *Cypripedium Lawrenceanum*.

M. JULIUS HYE-LE SEN, Coupure, Ghent, also represented Belgium with a small group of good things, embracing *Miltunia x Bleuan* *ros a*, a noble, pink-tinted form. *Odontoglossum luteo-purpureum* *Vuystekeanum*, with flowers of two shades of yellow; *O. cordato-crispum*, *O. sceptrum*, *Cypripedium x Leysenianum*, *Laelio-Cattleya* (*C. Lawrenceana x L. cinnabarina*) of the *L. C. x Highburyensis* class, with curiously roe-flaked flowers.

M. A. MADOUX, Anderghem, Brussels, also showed some good things, remarkable being the beautiful *Odontoglossum* (*Adrianae*) \times *Charlesianum*, with cream-white flowers profusely spotted with brown; *O. crispum* *Trianae*, with a purple blotch in the sepals; *Laelia Latona* *superba*, very brilliantly coloured, and other showy kinds.

M. CHAS. VUYSTEKE, Loochristy, Ghent, showed *Odontoglossum x crispum* *Harryanum* (*crispum x Harryanum*), a very interesting hybrid with the general features of *O. Harryanum*, but paler in tint and modified in form, as might be expected. Its nearest affinity among imported plants is *O. Wattianum*, which may be an analogous natural hybrid.

MESSRS. JAS. BACKHOUSE & SONS, York, showed various Orchids, their forms of *Miltunia vexillaria* being of very fine colour, that named *Empress Victoria Augusta* being of a bright rose-crimson.

W. P. BURKINSHAW, Esq., The West Hill, Hessle, near Hull (gr., Mr. Barker), sent *Cattleya Mendeli* *Amelia*, a very handsome light form; *C. Mossiae* *Barkeri*, like a lavender-tinted *C. M. Reinckiana*; and a fine form of *Cypripedium Rothschildianum*.

ELIJAH ASHWORTH, Esq., Harefield Hall, Wilmslow, Cheshire (gr., Mr. Holbrook), showed a fine example of the showy *Cirriophetalum Colletti*, with four spikes.

WALTER COBB, Esq., Dulcote, Tunbridge Wells (gr., Mr. J. Howes), showed a grand specimen of *Epidendrum prismatocarpum*, with nine spikes.

MESSRS. W. L. LEWIS & CO., Southgate, showed a very fine group, in which were excellent forms of *Odontoglossum crispum*, and other showy *Odontoglossums*; fine varieties of *Laelia purpurata*, *Cymbidium Lowianum*, *Cattleya Mendeli*, *C. Mossiae*, &c., *Cypripedium Mastersianum*, and other good species; *Oncidium varicosum*, *O. spilostrum*, *O. Marshallianum*; a prettily marked variety of *O. hastatum*, &c.

H. SHAW, Esq., Heathfield, Stockport (gr., Mr. J. Cliffe), showed *Miltunia vexillaria*, *Heathfield* variety, with fine large flowers; and the dwarf *Dendrobium*, known in gardens as *D. pulchellum*.

R. S. BOND, Esq., Surbiton (gr., Mr. Pead), showed a yellow spotted *Odontoglossum Wilckeanum*.

ROSES.

Just as prominent a feature of the large tent, as the Orchids are known to be, are the larger collections of Roses, the exhibits of both MESSRS. WILLIAM PAUL and of MESSRS. PAUL & SON, also of Mr. CHAS. TURNER, being again in this marquee. We never see finer Roses in pots than we admire at the Temple, and probably no better show of them occurs in Europe.

MESSRS. WILLIAM PAUL & SON, Waltham Cross, Herts, had a magnificent group. The ground was furnished with dwarf, well-flowered plants, and above these the fine heads of the standards, caused an appreciable effect. The face was made beautiful with boxes of cut blooms in brilliant colours, and others were grouped in ornamental baskets upon three-legged pedestals, that would make fine stands for flower-pots. Of varieties staged a good number were of Messrs. PAUL's own raising. A new one, named *Aurora*, which was granted an Award of Merit on this occasion, deserves a word of commendation. It has the appearance of being a capital doer, has warm, deep, salmon pink coloured bloom of large size, and more than this it retains the scent we look for in Roses to a much greater degree than is the case in many of the best modern exhibition varieties.

Others that are good at all times are *Clio*, *Medea*, *Anna Olivier*, *Empress Alexandra* of Russia, *Mrs. Jno. Laing*, *Crimson Queen*, *Coranna*, &c.

Mr. CHAS. TURNER as usual, furnished the end of the large tent with his *Roses* and *Pelargoniums*, and his *Roses* on this occasion formed an exhibit of loveliness any grower might be proud of. Last year Mr. Turner gave an importance to the Rambler Rose in his group; and as dwarfs or as trained plants in the form of an arch, their effect was equally gorgeous. The centre of the group was taken by an uncommonly large and handsome plant of *Junio*; and regarding the rest of the varieties, it is not needful to particularise.

The group from Messrs. PAUL & SON, Cheshunt, was placed in a corner of the same tent, and the standards, half-standards, and dwarf plants furnished it well. Some of the varieties that one picked out at once as the most effective were *Caroline Testout*, *Madame de Watteville*, *Ulrich Brunner*, *Elsie Fugier*, *Junio*, *Madame A. Chatenay*, and *Haileybury*, a showy crimson Rose. Then, there were several plants of the seedling *Polyantha* Rose named *Psyche*, which has already been described and figured in these columns.

and which may be recommended as a novelty of much value. Also a new Polyantha Rose Diana, a seedling from Turner's Crimson Rambler, producing small very double white tinted blossoms.

Mr. W. RUMSEY's collection of Roses at the entrance to Tent No. 4 included standard and other plants in pots, and ten or more boxes filled with cut blooms, considerable prominence being given to the variety Mrs. Rumsey, a new bedding or garden Rose of much vigour, and pretty warm pink or rose-coloured blooms.

Messrs. FRANK CANT & Co., Braiswick Nurseries, Colchester, had a group of Roses in pots in Tent No. 4, the plants facing both promenades. Many of the plants were well flowered, but we think we have seen this successful Rose-cultivator exhibit in better form. The season is a little early at present, and ere long the out-of-door Roses will be ready for exhibition. Then is Mr. Cant usually a formidable opponent.

plants in bloom at a given time. They were one of the pleasantest as well as a distinct feature of the exhibition, and it should not be long before they are popular plants in every garden of average extent and means. Awards of Merit were recommended to two of the seedlings shown, viz., Agatha, a pale salmon-pink flower, with richer throat, and Epirus, a beautiful satiny rose-pink. Some of the best of named sorts are Isabel Watson, violet-purple, the centre of each segment being scarlet; Cooperi, a lovely white flower; La Reine, a very free, rather small-flowering variety, the plant shown carrying seventeen flowers and buds; La Belle, a large seedling white; Brilliant, small-flowered, brilliant scarlet; Ovis, pink; Thalia, scarlet and violet; and Jessica.

Mr. G. J. PRITCHARD, 78, Godwin Road, Forest Gate, had a group of succulent plants, but not much flower, and in the midst of such a temple of flowers they would hardly be likely to engage much attention.

cut blooms. Mr. J. PREWETT had silvered-arches, gates, &c., decorated with Pelargonium blooms.

Other exhibitors of similar stands were Messrs. M. V. SEALE, of Sevenoaks; Mr. W. G. PARKER, 20, Oakdale Road, Sheffield; Miss DALTON, 28, Pilgrim Street, Ludgate Hill, London; Mr. W. SYDENHAM, Tamworth, and the LONDON WOMEN'S GARDENERS ASSOCIATION, Lower Sloane Street.

FRUIT AND VEGETABLES.

These products comprising food for the body rather than the eye, even though presented in singularly attractive form, were seen in considerable profusion, excelling the presentation of previous years, and generally in exceedingly fine condition. Notably attractive were—

Fruit Trees in Pots.—These came from Gunnersbury and Sawbridgeworth. Of the former Mr. Hudson, gr. to LEOPOLD DE ROTHSCHILD, Esq., had a big group in the large tent, arranged on the ground. There were in all nearly 100 trees. At the back were several Black Hamburg and Foster's seedling Vines in good fruit. These were trained up to semi-wire arches, that ran out over the fruit trees below in pleasing form. The stone-fruits included Cardinal, Early Rivers, and Lord Napier Nectarines. Hale's Early, Early Grosse Mignonne, and Amsden June Peaches; Governor Wood, Early Rivers, May Duke, Bigarreau de Schrecken, Frogmore Early, and Elton Cherries; St. John Fig; Jefferson Reing Claude, and Early Transparent Gage Plums; many of these being duplicated, and all in fine fruit. Fronting the group were boxes of splendid Auguste Nicaise, and Royal Sovereign Strawberries, and the new white French variety, Louis Cautier. Also Giant Early Rivers and Lord Napier Nectarines, and several Cherries.

On the other side of the tent, Messrs. RIVERS & SON, Sawbridgeworth, had a fine lot of trees, chiefly of their beautiful Nectarine Early Rivers. One comparatively small Standard carried 24 fine ripe fruit, richly coloured, as indeed were all the fruits shown. The collection included Hale's Early and Crimson Galande Peaches, Early Rivers, and May Duke Cherries, Early Rivers Plum, and Monaco Bianco, and Marseilles Figs. In a box were very fine Early Rivers Nectarines.

Collections of Gathered Fruit.—The finest collection of this character was set up by that famous gardener Mr. McIndoe, gr. to Sir JOSEPH PEASE, M.P., Hutton Hall, Guisborough. He had in all twenty-six dishes, inclusive, of Black Hamburg, Foster's Seedling, and Early Saumur Frontignan, the latter a round white-berried Grape, an all of exceptional excellence for the season. There were also eight superb-looking Melons, named The Model, a white-fleshed variety, from Best-of-All and Scarlet Premier. The fruits were externally very yellow and handsomely netted, and when tasted by the Fruit Committee, had nice flavour, but the outer flesh was hard. Also large single fruits of Yorkshire Beauty and Scarlet Premier. There were fine exquisite Oranges, Imperial Lemons, large Brown Turkey Figs, Black Tartarian Cherries; Grosse Mignonne, Bellegarde, and Condor Peaches, Early Rivers, Elruge, and Dryden Nectarines; Royal Sovereign Strawberries, Apples, and Tomatoes.

Messrs. G. BUNYARD & Co., Maidstone, set up a very remarkable and well-preserved collection of some 70 dishes of Apples, and one of fine Uvedale's St. Germain Pears. The Cooking Apples included Bramley's Seedling, Alfriston, Hoary Morning, Murphett's Seedling, Gascoigne's Scarlet, Ontario, a handsome American variety, as also King of Tomkin's County, Lord Derby, Lane's Prince Albert, one of the best; Belle de Pontoise, Bismarck, and Newton Wonder. Of well-kept eating varieties, Calville Blanche, Calville Malingre, Brownlee's Russett, Ribston Pippin, Cox's Orange Pippin, White Pearmain, Wadhurst Pippin, Cornish Aromatic, and Reinette du Canada, were capital. The entire collection showed rich colour and exceeding freshness. Backing the fruit were some small trees in pots of Emile de Heyst, Doyenné du Comice, and Louise Bonne Pears in nice fruit; quite small plants well fruited of St. John's Fig, and several plants of the Strawberry-Raspberry. These were about 12 inches in height, having Raspberry-like stems and leaves, but rather spiny, carrying white flowers, and some fruits yet imperfect and green, set in a dense ring of anthers. The only award made, was to a new American Apple Ontario shown by Messrs. G. BUNYARD & Co., Maidstone. The fruits were of good size, ribbed, colour clear yellow, much striped and flushed red, next the sun, the stalk an inch long, deeply inserted, eye open, also deep. The flesh is soft and very pleasant eating, it is evidently a good keeper (Award of Merit).

Mr. G. FEATHERBY, The Vineries, Gillingham, Kent, had a good flat of capital Black Hamburg Grapes, also bunches on a board finely coloured, good Hales' Early Peaches, Dryden Nectarines, Comet Tomatoes, Covent Garden Cucumbers, and Dwarf French Beans, all excellent.

Mr. J. RYDER, The Gardens, Hawkswick, St. Albans, had 16 superb fruits of Grosse Mignonne Peaches, the finest in the show.

From Mr. E. Beckett, gr. to Lord ALDENHAM, Elstree, were staged six fine Melons, Sutton's Al, and Masterpiece, The Countess, Blenheim Orange, Aldenham Perfection, and a fine green variety named Abundance. Smaller Melons in variety came from Mr. ROBINSON, Elsfeld House Gardens, Hollingbourne, Kent, the best being Netton's Eureka, and Victory of Bristol.

Mr. J. MILLER sent from Ruxley Lodge Gardens, Esher, a box of nice Royal Sovereign Strawberries.

A mixed collection, sent from Proscot Park, Berks, by Mr. W. L. Bastin, gr. to ALEX. HENDERSON, Esq., M.P., included several diverse seedling Melons, including Buscot Park Hero, Matchless, Telegraph, A 1, and Perfection; Tomatoes, Potatoes, French Beans, and Broccoli.

FIG. 128.—FLOWERS OF LILIUM RUBELLUM: FLOWERS ROSY-LILAC.

(Sketched at the Temple Show. See p. 321.)

Mr. GEO. MOUNT's Gold-Medal Roses from Canterbury were staged in No. 1 Tent. As usual from this establishment, cut blooms alone were shown, if we except a few profusely-flowered plants in 7-inch pots of Crimson Rambler. Most of Mr. Mount's blooms were displayed in boxes, but these were very effectively set amid blooms with long sprays and foliage, and with a suitable background. There were two dozen or more blooms of such varieties as Ulrich Brunner, Catherine Mermet, and Anna Olivier, but other sorts in fewer numbers. A box in which the Roses Niphotos and Catherine Mermet were associated alone was extremely pretty.

From Mr. J. RUSSELL, Richmond Nurseries, Surrey, was a group of plants of Rose Carmine Pillar, well-known for its large single, carmine-coloured flowers, and for its suitability for training to furnish pillars and such positions.

CACTACEOUS PLANTS.

These might be said to be constituted of Messrs. JAS. VEITCH & SONS, collection of beautiful hybrids of Phyllocactus. Messrs. Veitch have exhibited similar plants for several years, but never so well or largely as on this occasion. There were 450 plants, including 130 seedling varieties, now blooming for the first time, beside a large number of named sorts we have seen previously. It must have required much care and skill to obtain so large a number of

TABLE DECORATIONS, FLORAL DESIGNS, &c.

Tent No. 3 was, in a large measure, devoted to the display of arrangements of cut flowers, although individual exhibitors were allowed only a small space. One of the most prominent exhibitors in this section was the firm of B. S. WILLIAMS & SON, Piccadilly. They had a lovely basket of Carnations, two baskets of Orchids, and a mirror, the frame of which was composed of double white Narcissus bloom, and further adorned with Orchids.

The well-known firm of Messrs. PERKINS & SONS, Coventry, had a basket of yellow flowers and foliage, in which Cattleya citrina, various Oncidiums, Maréchal Niel Roses, Croton leaves, and Asparagus were used. This, in our opinion, was very lovely. Their shower bouquets of Orchid blooms also showed excellent taste.

A very good exhibit was made by Mr. MOYSES STEVENS, 146, Victoria Street, Belgravia, his best being a large white wreath and a basket of pink Pionies, and double white Narcissus blooms.

Messrs. JONES & SON, of Shrewsbury, who always exhibit well at the August show in that town, had pretty bouquets of Odontoglossums, Carnations, &c.

Mr. L. L. CALCUTT, Fernbank Nursery, Stoke Newington, had a number of gold-coloured wire stands, decorated with

VEGETABLES.

A very remarkable, though not a showy exhibit, was the collection of gathered Peas in large round baskets, each holding about half a bushel, sent by Messrs. SUTTON & SONS, of Reading. No such fine samples has ever been seen at this or, perhaps, any other May show: the varieties comprised Sutton's Early Giant, very fine long pods full of rich green peas; Bountiful, A 1, and Empress of India. Also wonderful fruits, twenty-four in number, of the firm's Cucumber A 1, also Peerless, Pride of the Market, Every Day, Matchless, &c. The entire collection was most pleasingly set in Maidenhair Ferns.

Another very nice exhibit consisted of nine boxes of Tomatoes and eight ditto Cucumbers, from Mr. S. MORTIMER, Farnham. The former comprised Sutton's A 1, Conqueror, Perfection, Earliest-of-All, Eclipse, Abundance, and Mitchell's Hybrid; the Cucumbers were Lockie's Perfection, Progress, Sutton's A 1, Improved Telegraph, Tender-and-True; and two seedlings, The Keeper, and Sensation, both remarkably prolific.

A wonderfully fine exhibit evidencing the finest quality, and covering a table thirty feet long, was the collection from Aldenham House Gardens, staged by Mr. E. BECKETT. There were large mounds of Broccolis, Sutton's Late Queen, Veitch's Model, Perfection, and others; and beautifully firm and white a heap of Veitch's Early Forcing Cauliflower; also giant Leeks, Mussleburgh, Lyon and Holborn Model. Various bundles of Rhubarb stems, too large; Cabbages, Ellam's Early, Flower of Spring, Model, and others; Sharpe's Victor, Sn wdrop, Harbinger, and Royal Ashleaf Potatoes; Duke of York, Golden Nugget, Red Dessert, Perfection, and A1 Tomatoes; delicious looking small fresh Radishes, Mustard-and-Cress, Dwarf French Beans, good Asparagus, Globe Artichokes; several diverse Potatoes, Marrows, Peas, Cucumbers, Carrots, Turnips, and many other things, all of high excellence.

Mr. Hayes, gr. to the MARQUIS OF NORTHAMPTON, Castle-Ashby, Northampton, had a smaller though very nice group. His best things were Asparagus, Cucumbers, Tomatoes, including Ham Green, Polegate, and Excelsior, Early Nantes, and Forcing Carrots, Ne plus Ultra, Dwarf French Beans, Potatoes, Radishes, Lettuce, &c.

Mr. FRANK CHAPMAN, Colchester, sent numerous bundles of Colchester Asparagus, very fine, and resembling Connover's Colossal; also a bundle of New Green, the tops of pale green hue, rather than purple.

An artistically-arranged group came from the Horticultural College, Swanley (Superintendent, F. GRAHAM POWELL, Esq.). This included standard-trained Cucumber plants, each carrying fruits set into mounds of Dwarf Peas, in pots, grouped around being fine heaps of Tomatoes, Potatoes, Picked Peas, Dwarf Beans, Cabbages, Broccolis, beautiful Radishes, Asparagus, Mushrooms, &c., the whole forming a singularly attractive feature, while the quality was excellent.

Truly a huge exhibit was that staged by Mr. Empson gr. to the Hon. Mrs. WINGFIELD, Amphil, Beds, covering a table seventy feet long. At the back ran The Daisy, Stratagem, and Lightning Peas. Climbing French Beans, and Long Pod Beans, in pots, and well fruited, also some good Tomatoes. Then there were Late White, Cattell's Eclipse, Mammoth, Model and other Broccolis; Jersey, Wakefield, Prizetaker, and Little Pixie Cabbages; a very extensive collection of Radishes, all as usual too large and old. Good Rochford's, Cardiff Castle, and Model Cucumbers; Duke York, Marden Parke, and Chiswick Red Tomatoes; Lettuces, Carrots, Asparagus, Mushrooms, Potatoes, and numerous other things with some good dishes of Strawberries.

Messrs. JAS. CARTER & Co., Holborn, included in their huge exhibit some capably fruited plants of Duke of York Tomato; also a good heap of fruits by the same, and of Perfection; also numerous fruits of Model Cucumbers, and mounds of climbing French Beans, and Stratagem, and The Daisy Peas.

Mr. J. NICHOLLS, Tooting, exhibited Dwarf White Celery, forced, but it was not well blanched.

Mushrooms.—Very fine lots of these useful funguses were sent by Mr. M. ADDEY, Ealing Road, Brentford, whose sample was not only young and firm, but showed surprising clusters; and from Messrs. MOUNT BROS., Canterbury, whose sample was older, and also were composed of massive clusters.

Lack of space obliges us to keep over the Prize List till our next issue.

ENQUIRY.

SALIX BABYLONICA: How far to the north in Britain does this tree grow?

NOTICES TO CORRESPONDENTS.

ALLAMANDA BLOSSOM: H. J. S. An attempt at doubling.

A NEW EXPERIMENT IN SENDING FRUIT FROM AUSTRALIA: Tasmanian. We are unable to learn anything about this. The Gulf of Bothnia is a steamer hailing from Glasgow, and owned there. It is likely to unload at Manchester.

CORRECTION.—In last week's issue of the *Gardeners' Chronicle*, p. 308, 27th line from bottom, "fronds" appears instead of "finds;" and in the winding up peroration "variation in shoots" takes the place of

"variation, in short;" both instances altering the meaning very materially. C. T. Druery.

FERN: G. A. The roots have been injured, if not killed, by the mycelium of some species of fungus, originating probably on half-decayed vegetable matter present in the soil. In its immature state we are unable to identify the species. The cure is obvious.

FLORAL-GUM: G. B. W. We do not know the formula, but the gum can be obtained from the dealers in horticultural sundries.

FRUIT-BOTTLING: Fruticus. Any of the cheap cookery-books would include the various methods in use. We know of no manual dealing exclusively with the subject.

FRUIT-BUSHES, ROSES, ORNAMENTAL SHRUBS: Fairintosh. We are unacquainted with the Scottish law on the subject of the removal of these plants by the outgoing-tenant, but the English law claims them for the landlord, unless an agreement exists to the contrary; or the tenant is a nurseryman, and the plants consist of plants of ordinary sale size.

IMANTOPHYLLUMS: B. P. The potting should be firmly done with the hands; use no rammer as this would cause bruising of the fleshy roots. The uppermost roots should come just beneath the soil.

INSECTS: B. W. W. The common woodlouse. Trap them with slices of Potatoes. Go round at night. The young ones may be killed by boiling water.

MUSHROOM-BED FAILING TO PRODUCE MUSHROOMS: Coventry. You do not tell us what heat was present in the bed when spawned, nor the temperature at which the house or shed was kept, or if the spawn was new or old. It is not the best way to proceed to mix dung and soil together as you have done. Did you separate the dung and short straw from the long straw, and was it repeatedly shaken out and moved about till it had parted with its rank odour and heat? Was the litter from a stable where corn-fed horses stood? Have patience, for if strong heat has not killed the spawn, Mushrooms may yet appear. If no Mushrooms appear in a month, throw out the bed and make a new one in a cool place, as a cellar or under trees. Beds made in wooden sheds at this season do no good.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number.—Bassett. Ribes speciosum, so far as we can determine from the specimen sent.—

E. S. M. Dimorphotheca pluvialis.—C. H. 1, Anthriscus vulgaris; 2, Glechoma hederacea; 3, Geranium Robertianum; 4, Veronica Chamædrys; 5, Potentilla anserina; 6, Erysimum Alliaria.—Tregenna. 1, Saxifraga granulata, double fl. var.; 2, next week.—G. T. A species of Euonymus, perhaps, E. europæus.—G. B. Piptanthus nepalensis.—D. C. H. 1, Uvularia perfoliata, Lathyrus Nissolia. Please send better specimens; remember when they reach us they are likely to be shrivelled beyond recognition, unless you pack them properly.—V. J. S. A variety of Cupressus Lawsoniana, Diplacus glutinosus.—J. M. O. 1, Bridgesia spicata; 2, Viola hirta; 3, Ægopodium podagraria; 4, Lycium barbarum.—Correspondent. O. Rossii majus. Thanks for flowers sent; they are both good varieties, the rose-tinted O. crispum especially so. Box marked fragile: Dendrobium crystallinum.—J. A. Caladium argyrites, and a crippled flower of Odontoglossum citrosum.—A. V. W. 1, Davallia canariensis; 2, D. Tyermanni; 3, Anthericum lineare variegatum; 4, Dracæna rubra; 5, one of the hybrid Rhododendrons.—W. T. 1, Pteris quadriaurita; 2, Adiantum concinnum; 3, barren frond of No. 1; 4, A. formosum; 5, Polypodium pustulatum; 6, Adiantum trapeziforme; 7, A. macrophyllum; 8, A. cardioclæna.—Mrs. H. Maianthemum bifolium, Ruscus hypophyllum.—C. H. O. Carex glauca.—E. T. Ashworth. Orchis pallens.—J. A. W. Euryclis sylvestris, Salisb. (Bot. Mag., t. 1419).—Tregenna, Prunus japonica, fl.-pl., not new.—W. H. M. Munches. Pyrus (perhaps a deeply-coloured form of P. Malus). Cannot name with certainty from such scraps.—B. 1, Clematis montana; 2, Prunus Cerasus.—J. H. F. Luisia tenuifolia.—B. M. D. Clematis montana.—Mr. Garnett. A distinct natural hybrid Odontoglossum, which we have not previously seen.

NEW SPECIES OF COTTON PLANT: Carl Dignowitz and Wulf-Wulff. We have no further information to give regarding this so-called new Cotton than appears in our issue for May 14 last. The plant

is probably not a Cotton (Gossypium), but some species of Malvaceæ, and of no commercial value.

"MITES": G. A. We should like to see some of these universal destroyers infesting your garden. Will you kindly send some. We know of no "mite" that is equally destructive to Eucharis and other bulbous plants, and to such diverse plants as Primula sinensis, Lobelia cardinalis, Calla, Echeveria, Cannas, Anthuriums, &c.

PEACH LEAVES DISFIGURED: W. T. The spots are caused by a fungus, Phyllosticta persicæ. Use against it sulphur washes, or the Bordeaux Mixture, or sulphide of potassium ½ oz. to a gallon of water. The worst leaves should be removed and burned.

PEAR SHOOT: G. A. The swollen corky appearance is due to a fungus, Nectria ditissima. The minute reddish warts appearing on the surface being the fruit of the fungus. The cancerous swelling should be cut out, down to sound bark and wood, and painted with clay and bullock's-blood, mixed with cow-hair so as to bind it together. In the specimen sent the bark is dead all round the shoot, and is lifeless beyond that point.

PEAS: Walton. Julius chiefly feed on decaying matter, but are not averse to living Pea-roots, &c.

PRESERVING FLOWERS: B. P. Lay the flowers and foliage naturally and thinly on sheets of coarse paper, inserting these sheets between a few other sheets; place them under a weighted piece of board, and examine them on alternate days, changing the paper they are in contact with for fresh paper. It is not possible to make their colours permanent, and it is advisable to attach a coloured drawing of the flower to each sheet.

PRUNING WEIGELA: W. P. Prune after the plant has borne the bulk of its flowers, unless it be an old almost flowerless bush, then prune in the late autumn; cutting hard into the old wood.

ROSE: S. B. J. We do not undertake to name garden Roses.

ROSE WITH GREEN CENTRE: L. D. D. The example sent is a proliferous one, several small flowers having come in the centre. It is not uncommon.

SPIRITS OF TURPENTINE AND LIVING PLANTS: F. C. We should advise you not to make use of this liquid in making any sort of grafting-wax; it might be injurious to stock or scion, and is not required. All that is wanted in making a grafting-wax to be used warm are tallow, bees'-wax, and a little resin, the last two being first melted, and the tallow added till the mixture loses the greater part of its stickiness.

SULPHIDE OF POTASSIUM: Potash. Ask for liver of sulphur.

TOMATOS: J. W. McHattie. The red-fruited variety is very solid and weighty, and having fruited so abundantly in three months from the time of sowing it is well named Early Cluster. The yellow-fruited variety, Prince of Wales, is very free in setting, of an attractive colour, medium size, and nice flavour; well adapted for consuming in the raw state. The forcing Turnip is one of the Navet varieties, commonly met with in continental gardens and markets. They are nice-eating, being tender and well flavoured when young, but soon getting hot and stringy. For hotbed-work they are excellent, being as quick as the flat white Dutch, and requiring less space per plant. The Teltau is a good form of Navet, but not so rapid in growth as some other varieties. We always welcome any vegetable, new or old, that is out of the common run.

VINES: Japonica. The leaves sent show great ravages from thrips and red-spider, and their crippled appearance is mostly due to these insects. The soil is not exactly suitable for Vines, and considering that the Vines have been so lately planted, and doubtless in a new border, it could not have consisted of quite the best kind. Can you not get some experienced gardener to inspect the Vines and give you hints on their culture?

DIED.—REINHARDT MAITRE, at New Orleans, on April 14, 1898, at 7 o'clock, A.M., after a long lingering illness, aged 67 years 9 months.

(For Markets and Weather, see p. x.)

THE

Gardeners' Chronicle.

SATURDAY, JUNE 4, 1898.

EVAPORATION FROM FRUIT TREES.

WHEN Dr. Lindley was editor, in the early days of the *Gardeners' Chronicle*, some fifty years ago, he suggested to J. B. Lawes, Esq., of Rothamsted (now Sir J. B. Lawes, Bart.), who was then beginning to publish some of his investigations, that it would be desirable to institute a series of experiments having for their object the determination of the relative evaporation occurring in evergreen and deciduous trees. In consequence, three young plants were selected each of the following, i.e., Spruce Fir, Portugal Laurel, evergreen Berberis, Yew, Holly, common Laurel, Larch, Oak, deciduous Berberis, Ash, and Sycamore, duly weighed and placed in zinc pots, the weight of these and the soil employed being ascertained. It would be unnecessary here to detail the method adopted for the regulation of the supply of water, and determining the amount of evaporation, but the same patient care in observation and strict accuracy in recording the results which have given the Rothamsted experiments so high a value in the eyes of scientific and practical men, were exercised in every way. The results were published in the *Journal of the Horticultural Society*, and established two interesting facts, one being that a considerable amount of evaporation takes place during the winter months from both evergreen and deciduous trees; and the other, that the proportionate evaporation from deciduous trees or shrubs when divested of their foliage is much greater than would be supposed, considering that the whole of the moisture then lost passes through the bark of stem and branches. For example, in four months, from December 22 to April 24, it was found that the common Holly lost 23,780 grains, while in the same period the Larch lost 11,570 grains; the evergreen Berberis lost 24,530 grains, and the deciduous Berberis evaporated 11,740 grains—in each case nearly one-half of the total evaporated from the plants furnished with leaves.

The subject of winter evaporation has been studied by several investigators since, and in quite recent times Professor L. H. Bailey has given it his attention, with especial reference to hardy fruit trees. A small branch of an Apple-tree, weighing 4,425 grammes, was taken early in April; the cut end was closely sealed with wax,

and the loss of weight by evaporation was determined at short intervals for three days, the result being a total loss of 39 centigrammes, equal to 8.8 per cent., or a nearly constant average loss of half a centigramme per hour. As this experiment was conducted in a living-room, where, presumably, the air would be considerably drier than out-of-doors, it can only serve as a comparative indication of the loss occasioned by evaporation under natural conditions. To ascertain if there was any foundation for the statement that "the rate of the loss of moisture from trees in winter determines the relative hardiness of different varieties of Apples and some other fruits," twigs of nine well-known American Apples were weighed, sealed, and treated as in the preceding experiment, except that they were placed in an "open shed," instead of in a room. The loss in two days varied from 2.8 per cent. to 10.3 per cent., but it was found that "the percentage of loss of moisture bears no relation to the supposed hardiness of the varieties." It was, however, observed in some further experiments that there was a great difference in the loss of moisture from several twigs of the same variety. Thus, in five twigs of Duchess of Oldenburg, the loss ranged from 6.07 to 13.1 per cent., while the same number of Baldwins varied from 9.74 to 11.5 per cent.

More elaborate investigations were commenced by Mr. A. L. Kniseley (one of Prof. Bailey's students) in January, 1897, in which twigs were taken of Apples, Pears, Plums, Peaches, Cherries, and Apricots, besides several common deciduous trees. The specimens of the fruit-trees were from 3 to 7 inches in length, and the cut ends were plunged in melted paraffin. They were then either tied to the trees or placed in equally exposed positions, and weighed at the end of seventy-two hours, and again after another seventy-two hours' exposure, making six days in all, the weather varying during that time in brightness, but the temperature was below freezing-point (Fahrenheit) throughout the period. The principal results obtained are embodied in the table appended, which has been condensed from the original record, all the weights being in grammes and decimals:—

Fruit.	Twigs.		Loss of Moisture.			Loss per square foot of surface.
	No.	Weight.	First three days.	Second three days.	Total.	In 24 hours.
Apple ...	3	4.5158	.0316	.0505	.0821	.338
Pear ...	4	10.424	.0465	.0919	.1384	.354
Plum ...	3	7.0359	.0609	.1041	.1650	.429
Cherry ...	1	1.9245	.0100	.0173	.0273	.225
Apricot ...	4	6.9312	.0425	.0861	.1286	.268
Peach ..	2	3.8156	.0379	.0688	.1067	.410

Mr. Kniseley remarks in reference to the bearing evaporation has upon injuries by frost, "in freezing weather the moisture, even though frozen, is probably evaporated from the tree-tops; and the sap being frozen, does not flow up from the roots and replace the evaporated moisture. Thus the equilibrium between tree-tops and roots is unbalanced, and it is at this time that the twigs become shrivelled by reason of moisture being lost and not replaced." The shrivelling here noted I have often observed in dry winters, and though it is not always attended by actual frost injury, as appears to be the case in the United States, yet it is commonly followed by feeble growth in the spring, the buds starting weakly or irregularly.

For a considerable time it has appeared to me that the evaporation of moisture from deciduous trees during winter nights has a material influence upon the varying behaviour of fruit-trees in different seasons, both as regards early or late planting, and early or late pruning. There are many points in favour of early planting which need not be detailed now, and it is a practice which general experience renders desirable; but the fact remains that in some seasons there is no appreciable difference between early and late-planted trees where equal care has been exercised, and occasionally the late-planted trees seem to have the advantage. Frequently, however, the difference is more marked as regards the first pruning after planting, and it is this which has caused some advocates to strongly urge the desirability of delaying the first pruning until the season after planting, while others as strongly advise the pruning to be done immediately the trees are placed in the ground. Such divergences of opinion do not arise without substantial reasons, though they are not always easy to discover or explain. They are usually founded upon desultory and unmethodical observations, so that it is difficult to arrive at a clear understanding respecting them. But in view of the facts recorded, there can be no doubt that in dry winters a great quantity of moisture is evaporated from trees which, under some circumstances such as those set forth by Mr. Kniseley, may be extremely prejudicial to the starting and development of the buds in spring.

One point, however, which has a considerable bearing upon the matter is not dealt with in any of the experiments described, and that is, when a tree is pruned a large number of cut surfaces are exposed from which it may be supposed the evaporation would be much more rapid than through the bark. The best method of determining this would be that adopted at Rothamsted, namely, selecting small trees, then weighing them after pruning, and continuously over a period sufficient to give definite results. It seemed to me, however, that some approximation to the truth might be gained by the following means: In January ten shoots each were selected of as nearly equal diameter as possible from about thirty-six varieties of Apples, and they were all cut to 30 centimetres in length (about two-eighths of an inch less than a foot). The shoots of each variety were then weighed and suspended amongst the branches of trees, in a similar position as regards exposure to that occupied by those from which they were cut. They were weighed four times: immediately before placing them out in the trees, at the end of two days, again after the lapse of a week, and then at the end of a month from the second weighing. It appeared possible that some proportionate differences might be found in the loss from the slender shoots as compared with the larger and more vigorous shoots, a selection was therefore made, and they were classed in three degrees, 1st, slender; 2nd, medium; 3rd, large; ten varieties being included in each section. The results are shown in the following tables, all the weights being taken in grammes:—

FIRST SECTION: SLENDER GROWTHS.

Weight in Grammes.

Variety.	Number of Shoots.	Weight after Cutting.	Weight after 2 Days.	Weight after 9 Days.	Weight after 39 Days.	Total Loss.
Cox's Orange ...	10	57	52	49	38	19
Mannington's Pearmain ...	10	52	49	41	37	15
Ross Nonpareil ...	10	43	41	36	32	11
Margil ...	10	43	40	33	30	13
Wealthy ...	10	45	42	40	34	11
Cockle's Pippin ...	10	37	35	30	27	10
Gravenstein ...	10	54	52	45	38	14
Rivers' Early Peach ...	10	55	53	48	40	15
Scarlet Pearmain .	10	46	44	38	32	14
Dutch Mignonne .	10	37	35	30	25	12

The loss in the first two days was remarkably uniform, averaging 2.6 grammes. The average loss for nine days was 7.9 grammes; and for the whole period 13.4 grammes for the ten shoots of each variety.

SECOND SECTION: MEDIUM GROWTHS.

Weight in Grammes.

Variety.	Number of Shoots.	Weight after Cutting.	Weight after 2 Days.	Weight after 9 Days.	Weight after 39 Days.	Total Loss.
Brownlee's Russet	10	65	63	56	48	17
Fearn's Pippin ...	10	70	67	60	50	20
King of the Pippins ...	10	65	62	55	47	18
Sturmer Pippin ...	10	67	65	58	51	16

A still further increase in loss is shown in these varieties, but surprisingly uniform throughout. Average loss in two days, 3.0 grammes; in nine days, 11.4 grammes; in thirty-nine days, 22.7 grammes.

The weather conditions during these observations were variable, but it was generally dry, the rainfall scarcely exceeding an inch, with frequent frosts. It will be seen on comparison of the tables with Mr. Kniseley's that the average weight of the shoots was greater in the case of those I tested. For instance, the average weight per inch of the Apple shoots in the American experiment was .3763 grammes; in my specimens the average weight per inch was approximately as follows:—In the first section, .3908 grammes; in the second, .5533 grammes; and in the third, .7333 grammes; so that they were presumably larger, and therefore more bark surface was exposed. But allowing for this, the loss by evaporation was nearly double that recorded by Mr. Kniseley, and therefore the difference may be fairly considered as mainly due to the cut surfaces exposed. When such surfaces are upon the living plant instead of separated shoots, it may be presumed that the evaporation would be enormously greater (at least, until the tissue had healed sufficiently to check it), and this is the loss which in severely dry winters might produce injurious results that would point to pruning immediately after autumn-planting being a source of danger.

The subject is an interesting one, and would require a carefully-devised series of experiments to treat exhaustively. My remarks are offered only as a brief review of the matter, and are intended to be in a measure suggestive. F.R.H.S.

ORCHID NOTES AND GLEANINGS.

DENDROBIUM NOBILE.

THE usefulness of this handsome old species is well exemplified in the gardens of T. F. Blackwell, Esq., The Cedars, Harrow Weald, where it has been in

bloom for several months. Mr. J. Dinsmore grows a number of small and middling-sized plants, which he brings on in succession, and thus has them in bloom for a considerable period during the spring and early summer. At present a pretty specimen of the best type covered with flowers occupies the centre of a group in the intermediate-house where the Orchids are well grown, arranged with scarlet Anthuriums and foliage plants. Arranged with the specimen of *D. nobile*, before alluded to, are several smaller ones, plants of *D. fimbriatum*, *D. moschatum*, and other Dendrobies, and on the side stages are some finely flowered *Odontoglossum Halli*, *O. cirrosium*, *O. crispum*, *Miltonia vexillaria*, *Miltonia Roezli*, &c., and on one side of the central stage good varieties of *Cattleyas*, and a fine example of the elegant yellow *Oncidium flexuosum*. Considering that but a limited number of Orchids are grown at the Cedars, it is surprising the number of showy kinds there are in flower there at all seasons.

STRAWBERRIES AT HATFIELD.

UPON reaching Hatfield Gardens, my first request was to be shown the Strawberry-houses, for to see them was my primary object. The first house was a 100 feet lean-to, some 8 feet wide. Fine shelves, bringing the plants near the glass, run the entire length. One half of the house was filled with *V. Héricart de Thury*, President, Sir Charles Napier, and others, but the other half was full of Royal Sovereign exclusively, carrying a marvellous crop of ripening fruit. There were in this block 400 plants of the variety. On every plant the fruits were wonderfully fine, quite equal to those figured in *Gardeners' Chronicle* last week; and a look from the end of the house along the lines of fruit hanging from the plants was a revelation. In another large span-house were 800 plants not quite so forward, but those at the warmest ends were carrying grand ripe fruits, of the finest form, and of that rich deep scarlet hue for which Royal Sovereign is famous. All round the house were four rows, and on the broad centre stage six rows. In every case the plants were placed so that the fruits were distant from the alley, the object being to prevent, so far as ordinary precaution could, the fruits being injured by the water-pots. I also saw a third, though smaller houseful, and hundreds of plants on tall shelves in Carnation and other plant-houses; upon all these the average number of fruits carried was nine. It is interesting to find that the thinning is done before blooming is finished. This practice is based on the belief that even the carrying of superfluous flowers after the needful number have expanded is a waste of strength.

Outdoors, standing in an exposed wind-swept area, were some 2000 plants yet for use if needed, and if not required, the blooms being now picked out, they will fruit well in the autumn if planted out. Altogether, about 8000 plants are annually potted. Of all the varieties, probably, one-third are Royal Sovereign, because it has at Hatfield proved to be, without exception, the finest forcing variety; outdoors also it is one of the very best. But something more than ordinary culture seems needful to produce such a fine crop and superb samples. Mr. Norman, however, states that it is but a matter of attention, and nothing more. He plants early in the autumn in rows some 30 inches apart strong-rooted runners purposely to furnish plenty of extra early runners for pots. That is common practice now. These, as I saw them recently, had been lightly mulched, and the trusses of flowers were being gathered as rapidly as they developed. Layering into pots is performed as fast as runners are formed, and these in dry weather get frequent watering. But the chief work is found in the final potting, which takes place as soon as the runners have become well established in their first pots. In all cases 7-inch, or large 32-sized, pots are used. Each one has placed in it fully one-fourth its depth of crocks for drainage, some have even one-third. I saw several spent plants turned out of the pots, and in each case the quantity of drainage was unusually great. On the crocks is laid a small portion of moss to prevent choking, and then on that

a sprinkling of clear soot. The compost is almost exclusively a stiff, turfy loam, almost fresh, the grass being pulled from the turves, and the soil well chopped up. Much of this soil had the firmness of clay, and it was rather rough than fine in texture. Potting is done very firmly. The plants are then, as is usual, stood on a hard coal-ash floor fairly close together, and in dry weather watering is carefully attended to. Water-logging is impossible owing to the abundant drainage given.

The grower's aim is to secure stout, sturdy, well-exposed leafage, solid single crowns, and a pot well filled with fine fibrous roots. All the plants turned out of pots showed this feature admirably, there being an entire absence of large fleshy roots. No doubt, the very firm soil, ample drainage, and absence of animal-manures conduces to this.

Wintering is of the most exposed nature, for the plants remain all the season just where placed after potting, with some ashes amongst them, and around the edge of the entire block. Only some needed for the earliest forcing are placed in a frame, so as to forward them slightly. All plants as needed are brought on tentatively, the temperature, at first low, being gradually raised, as sudden excitement causes the crowns to break ere the roots have become active. No form of stimulant is given until fruits are well set, and even then almost entirely in liquid form, and diluted. Practically, the soil used being so strong and full of fibre, seems to possess all food requirements. No special manure is employed. Soot-water, stable and cow-shed drainage, and similar simple liquids, constitute the chief manures given, and these are withheld when colouring is well advanced. A. D.

THE ROSARY.

CHINA, POLYANTHA, MOSS, AND PRO-
VENCE ROSES.

THOSE classes of summer and autumn-flowering Roses which are of great value for garden cultivation, have of late years been greatly enriched by new and valuable introductions, for the most part of British and French origin. One of the most important of those novelties, however—a climbing Polyantha of attractiveness and decorative capability, while owing to its great popularity to an English cultivator, was originally brought from Japan. On the other hand, two of the finest of the most recent additions to our China Roses, both of these highly distinctive in colour, and possessing other attributes of hardly less importance, were raised and introduced by that veteran rosarian, Mr. William Paul of Waltham Cross. I refer to the varieties denominated respectively Queen Mab and Duke of York, of which the latter has been awarded a First class Certificate by the Royal Horticultural Society. I have never seen these varieties so impressive anywhere else as at Waltham Cross. I have an idea that China Roses, being of a somewhat delicate nature so far as regards the texture of their flowers, are greatly affected when grown in the open air in a wet climate like ours, by the influence of rain; this is altogether prevented when they are grown under glass, for which, I may add, Queen Mab and Duke of York are admirably adapted. Under such conditions, observation has taught me, they are seen at their best. Another modern China Rose of great fascination, by reason of its exquisite colour and the extreme beauty of its foliage, is Laurette Messimy, for which we are indebted to the late M. Guillot. It is not so subject as many of its class to the influence of adverse atmospheric influences; and from the middle of May till the end of November (often much later), it is never out of bloom. Grown side by side with such varieties as the "brave old Monthly Rose," as Dean Hole has called it, the beautiful dark-hued Cramoisi Supérieur, or the pure white Ducher, it offers a charming contrast to these. Several of the Chinas are not far behind the Tea Roses in graceful effect.

Most of the dwarf Polyanthas, as I have already

indicated, are denizens of France. There is, however, one exception to the general rule, viz., the variety entitled Little Dot (white, with salmon-pink shading), raised by the late Mr. Henry Bennet, to whom in other directions, we owe so much. Of the continental Polyanthas, the most attractive, in my experience, are Perle d'Or, nankeen yellow, with deep orange centre; White Pet, whose colour is suggested by its name; Etoile d'Or, citron-yellow; Gloire de Polyantha, deep rose, shading into white in the central petals; and Anne-Marie de Montravail, whose snowy-white flowers, produced in great abundance, have a perfume rivalling that of Andromeda flori-

are the Crested Moss—supposed to be a variation from the old Pink Provence—which was originally discovered growing out of a convent wall near Berne, in Switzerland; this Rose is uniquely interesting, and, in the language of Shakespeare, applied to a widely different object, "bearded like a pard;" certainly the most heavily crested of them all. But by far the loveliest of Mosses are those pure white varieties, viz., the white Bath (raised by Salter at Clifton, a suburb of Bristol in 1810); and that notable French creation, Blanche Moreau. If I were strictly limited to one Moss Rose, I should undoubtedly choose this. During last summer for several weeks of almost uninterrupted

common Indian Fig, and cylinder-branched (*Cylindropuntia*), of which *O. arborescens* is an example. Most of the latter group are remarkable in having a loose papery-sheath over each of their large spines, the tip of the spine projecting slightly through an opening at the top. *O. tunicata*, of which good examples may be seen at Kew, is one of the commonest of this group.

There are about half-a-dozen species, all natives of the Argentine Republic, which differ from all other *Opuntias* in having long, flat, paper-like "spines" springing from among the tufts of short bristles, which crown each of the hump-like tubercles of the

FIG. 129.—PAPERY-SPINED OPUNTIAS: 1 *OPUNTIA PAPYRACANTHA*; 2, A FORM OF *OPUNTIA PAPYRACANTHA*.

bunda. Of climbing Polyantha Roses, the grandest is undoubtedly Turner's Crimson Rambler, to which allusion has already been made; this great climber is especially fine on a south or west wall. One of its superb crimson trusses in my own garden last summer had eighty brilliant flowers, which kept their colour for several weeks. This special qualification, combined with its marvellous brightness, makes it invaluable. Agla and Claire Jacquier are yellow climbers of greatly less attractiveness. Polyantha grandiflora, a white variety, with luminous foliage, is a splendid pillar Rose.

Among the Moss and Provence Roses, which by reason of their close relationship should be accounted as pertaining to one section, my own supreme favourites

calmness and sunshine, it was much more beautiful, alike in bud and fully-expanded blossom, than I have ever had the privilege of seeing it before. It is something to have seen such a Rose as this "in the most perfect phase of its possible beauty." David R Williamson.

PAPERY-SPINED OPUNTIAS.

THE genus *Opuntia*, as at present constituted, comprises about 150 species, two-thirds of which are natives of North America, the other third being scattered over South America and the West Indies. Its great variety of forms are separated into two groups, viz., flat-branched (*Platopuntia*), represented by the

stem. These are known as the broad-spined *Opuntias* (*Platyacanthæ*), and several of them are in cultivation under such names as *O. Turpini*, *O. diademata*, and *O. glomerata*. Very little appears to be known about them, even to botanists, and so far as I know they never flower under cultivation. The most striking of the species of this group is that represented in the illustration (fig. 129) taken from a specimen sent to the Editor, and which has lately been added to the Kew collection through the kindness of Señor Douglas Junor of Floresta, Buenos Ayres, a dealer in Cactaceæ. He calls it *O. plumosa nivea*, but it is, no doubt, the *O. papyracantha* of Philippi, a native of the Argentine Cordilleras.

The plant figured has grey-green, ovate branches,

2 to 3 inches long, the surface broken into broad tubercles $\frac{1}{2}$ inch apart, each crowned with a dense, brush-like tuft of short brown bristles, and two or three sub-erect, flat, thin, cartilaginous, paper-white appendages, which are neither leaves nor spines nor sheaths, but probably modifications of the latter, the spines they once covered having been suppressed. These appendages are from 1 to 3 inches long, $\frac{1}{4}$ inch wide at the base, tapering to a fine point, the margins more or less ragged. The plant at Kew is thriving in a tropical-house, and it looks as if it will not be difficult to manage. The plant numbered 2 in figure appears to be a form of *O. papyracantha* without the paper-like spines. The two were sent together. W. W.

SYDENHAM TEAST EDWARDS.*

IN the *Gardeners' Chronicle*, December 4, 1897, p. 405, Mr. F. W. Burbidge expressed a desire that I should communicate what I knew concerning the history of *The New Flora Britannica*, which I willingly do, though I doubt whether there are many readers of the *Gardeners' Chronicle* who take as much interest in bibliographical researches as Mr. Burbidge and myself. For that reason I will be brief. Ten years ago, I contributed to the columns of this paper a succinct history of the *Botanical Magazine*, and kindred English contemporary literature, and among other things I gave some particulars of Sydenham T. Edwards's connection with that and other illustrated horticultural and botanical publications. At that date I only knew of the existence of the work in question under the title of *The New Botanic Garden*. Indeed, until Mr. W. E. Gumbleton came to Kew towards the end of last year to examine the Kew copy, I was unaware that *The New Flora Britannica* was exactly the same, excepting the title. But there are still further complications. As stated (*Gardeners' Chronicle*, December 11, 1897, p. 417), the same plates illustrate a work which appeared under the title of *A Complete Dictionary of Practical Gardening*, by Alexander Macdonald, 1807. This, so far as my researches go, was the first issue of these excellent plates, and the name Sydenham Edwards appears as the artist, and F. Sansom as the engraver, in each case. Therefore, it was hardly the cause, and certainly not the consequence, of his secession from the *Botanical Magazine*. It is probable that the title *New Botanic Garden* was substituted for *New Flora Britannica* (as being more appropriate), for a part of the same issue; because the date, 1812, and everything else, is the same. Although the *Dictionary* is dated 1807, there is evidence that it appeared in parts, the plates being variously dated 1805 and 1806; these dates, and the general lettering, are the same in the *New Botanic Garden*, and the letterpress relating to the plants figured is almost word for word the same. The *Dictionary*, of course, is much thicker, consisting of two volumes. The letterpress in the first volume runs to 3 P in the signatures, and to 4 D in the second. According to Johnson (*History of English Gardening*, 1829), Alexander Macdonald was the pseudonym of a Dr. R. W. Dickson, of Hendon, Middlesex, "author of several agricultural works," concerning whom I have learnt nothing further. Britten and Boulger (*British and Irish Botanists*) add nothing.

R. Taylor (now Taylor & Francis) was the printer of the *Dictionary*, and G. Kearsley the publisher; whilst F. Bensley, of Bolt Court, Fleet Street, printed the *New Botanic Garden*.

Although I have failed to find any information on the early life of Edwards, or indeed, any connection with his social relations, I am able to give some further particulars of his professional career.

In the twenty-ninth volume of the *Botanical Magazine* (1809), immediately following the text to plate 1232, in the Kew copy, there is a notice to

* Edwards's second name has been variously given as Teak, Taste, &c., but, in answer to my inquiry, the Rev. R. H. Davies, vicar of Chelsea Old Church, informs me that it is spelt as above on the commemorative tablet in Chelsea Church.

subscribers concerning the artists who had drawn the figures published therein up to that date. It seems that some friend had given out that J. Sowerby was the designer of a large proportion of the figures; but the editorial note referred to above states that with the exception of sixty-seven executed by Sowerby (which are all indicated in detail), and eight by Sansom, the engraver, in vol. vi., the whole were done by Edwards. By mistake, twelve drawn by Edwards were attributed to Sowerby. These are indicated, as well as the unsigned ones drawn by Sowerby. Until I discovered this note I was under the impression that W. Curtis himself had drawn the figures of many of the unsigned plates in the early volumes. This view was shared by Dr. A. Curtis, of Staines,* who supplied me with many facts in the history of the family, and through whom Kew purchased some 1600 original drawings, which, with few exceptions, were published in the first series of the *Magazine*.

In 1828, Samuel Curtis, then proprietor, published his *General Indexes to the Plates figured in the First Fifty-three Volumes of the Botanical Magazine*, preceded by *Memoirs of the Life and Writings of William Curtis*, the founder of the *Magazine*. From this I extract the following particulars relating to Edwards:—"But the artist of most use to Mr. Curtis was Sydenham Taste (*sic*) Edwards, who was introduced to him for the purpose of his patronage by a Mr. Denman,† who if we are not mistaken, was at the time town-clerk of Southampton. Mr. Denman, being of a scientific turn of mind, and happening to be at Abergavenny, noticed Edwards, whose father was a school-master, and the organist there. Young Edwards, whilst a boy, had copied some of the plates of the *Flora Londinensis*, which were shown to Mr. Curtis, who was so pleased with them that he sent for him to London, and had him instructed in drawing, &c., in which he improved very rapidly, and soon became able to draw and etch the plates of the *Flora Londinensis*‡ and the *Botanical Magazine*. The drawings for the magazine were entirely his own for many years, and were executed with a correctness not before known in periodical publications. It was not to plants alone that Mr. Curtis had directed the genius of Edwards. He attended him on most of his excursions in search of natural history; and whenever any curious bird was shot, any curious insect taken, or any natural object of curiosity, it was his business to make a correct drawing of it. . . . In this manner many years were spent, and Edwards was the companion rather than the servant of his patron up to the death of Mr. Curtis."

This event occurred in 1799, but Edwards continued sole artist for the *Botanical Magazine* until 1815, when, in conjunction with John Bellenden Ker (previously Gawler), he founded the *Botanical Register*, on much the same lines as the *Botanical Magazine*, though he added floral analyses to some extent.

This step on the part of Edwards was regarded as an act of ingratitude by the Curtis family, and Samuel Curtis, in the memoirs from which I have already quoted, while fully recognising his talent, alludes to it in the following terms:—"After the death of Mr. Curtis, Edwards continued for years to draw entirely for the *Botanical Magazine*; which taking up but a small proportion of his time, he was noticed and employed by many persons of distinction, who were either fond of science, or lovers of correct and highly finished drawings of plants or animals. He published a work on dogs (*Cynographia Britannica*), in large quarto, on his own account; and it would have been more in unison with common gratitude; and more to his own peace of mind, in his last illness, if he had not been persuaded to begin a work in direct opposition to the *Botanical Magazine*; by which he had risen, and which work, after his patron was dead, was the support of his widow, daughter, and grand-

* Britten and Boulger, *Biogr. Index*, give Edwards's connection with the *Bot. Mag.* as 1799-1814; and B. D. Jackson, in *Dict. Nat. Biogr.*, as commencing in 1798. I may add that the first eight plates of the *Botanical Magazine* are dated 1786, and the first volume 1787.

† Elsewhere spelled Denham.

‡ This is evidently an error so far as the *Flora Londinensis* is concerned, as the dates alone prove.

children. Besides, there was no necessity for such a work, as the public were well satisfied with the *Magazine*, in every respect, without burthening science with another exactly the same except the title; which Mr. Gawler and Mr. Edwards, to distinguish it from *Magazine*, called *Register*, and charged it at a higher price."

It will be observed that Samuel Curtis, in very clumsy prose, lays great stress on Edwards's want of fidelity to his "patron," to whom he gives the prefix of "Mr." throughout, while withholding it from the artist. As a matter of fact, there were already many rivals in the field, and several in some respects superior to the *Botanical Magazine*; and Edwards was probably tired of being "patronised," or of being connected with a publication which was very feebly conducted by William Curtis's immediate successors. Whatever may have been the cause of the severance, Edwards and Ker were joined by Sansom, the engraver, and it must have been a serious matter for the proprietors of the *Magazine*. Edwards illustrated William Curtis's *Lectures on Botany*, his *British Grasses*, his *Companion to the Botanical Magazine*, and other works. W. Botting Hemsley.

A FINE SPECIMEN OF DENDROBIUM NOBILE.

WE have on former occasions afforded our readers illustrations of fine specimens of this beautiful late spring flowering species of Dendrobe.

In some cases, notably that of Mr. H. C. Prinsep's plant, figured in the *Gardeners' Chronicle*, June 4, 1892 p. 725, the annual pseudo-bulbs are removed when flowering has ceased, and the plant is induced by a high temperature and a humid atmosphere to make new and strong growths that will flower freely the following year. This method of culture is not, however, that commonly followed, which is to remove only those pseudo-bulbs that have flowered, perhaps to the extent of half to two-thirds of the whole, and subject the plant to ordinary Dendrobium-house or stove conditions, and with very good results. As we see in the fig. 130, p. 341, which shows a plant grown by Mr. M. E. Mills, gardener to F. Lloyd, Esq., Coombe House, Croydon.

NURSERY NOTES.

MESSRS. HUGH LOW AND CO.

OWING to the removal of the head-quarters of this firm from the well-known nurseries at Clapton to the newer ones at Bush Hill Park, a mile or two on the London side of Enfield, considerable additions are now being made at the latter place with a view to providing the necessary house-room for the Orchids, &c., that hitherto have been cultivated at Clapton. The London nurseryman may be said to live in fear of the builder. He is ever sensible that sooner or later the builder will render his position untenable, by so surrounding his establishment with houses—and chimneys—that successful plant-growing will be a sheer impossibility. And when, after much expense and worry, he has perforce moved further from the city, the energetic builder follows, and commences his thwarting work afresh. It is several seasons since our last visit to Bush Hill Park, and how the place has changed! Then it was really outside London, and looked as if it had been rejected by the builder, and was struggling on to exist in his absence. Messrs. Low had been at Bush Hill nearly nine years, and their position seemed safe. Now, the village is thronged with masons, the best of the roads are planted with Rhododendrons and other flowering-shrubs; houses have been built in scores; one cannot get to the nursery without stepping over the clay thrown out to make more foundations, and a large Board-school stands close to the nursery gates. In spite of all this, however, Messrs. Low have "come to stay," at any rate, for years to come; and it will take Mr. Builder a good number of these to oust them. At present, what a contrast the place presents to Clapton! How much more favourable to

plant cultivation! Undoubtedly the Orchids will thrive better in their new houses in a new nursery.

In company with Mr. Stuart Henry Low, we first inspected the *Odontoglossums* in two new houses, each 150 feet long, at one end terminating in a corridor fitted with rockwork, and suitable for the display of extra-fine specimens in flower. Into this corridor the doors of both houses open, and it will connect them with two other *Odontoglossum*-houses yet to be built. The two houses already noticed contain a very large number of plants indeed, healthy in appearance, and many of them carrying flowers; whilst the varieties frequently were admirable. Of *O. crispum* there was, for instance, a nearly white flower of the virginale type, another with characteristic red blotches, a third with a very fine spike holding fourteen large, firm flowers, the colours being white with yellow disc, and a red

section. There are, however, several very pretty rose-coloured varieties now in bloom. *O. Pescatorei*, *O. cirrhosum*, *O. macranthum*, *O. Halli*, *O. Edwardi* and others were present in numerous good forms. But we must now pass from the corridor above-mentioned into a house of *Cypripeds*, where the number of plants is far from commensurate with the value of them. The choice species, varieties, and hybrids have been gathered together here, and with *C. insigne* *Sanderæ* and *C. Lawrenceanum* *Hyeannum* they will be most interesting as the plants flower. Then there are some of the choicer *Cattleyas*, and a number of plants of *Oncidium Kramerii*, one of which, in bloom, is the largest-flowered form we remember to have seen.

We next pass into the hybrid *Dendrobe*-house, where there was little flower, but the plants are apparently very happy. The hybrids *Burfordiense*,

Passing to a group of *Cattleya*-houses we find four structures of about the same length as the *Odontoglossum*-houses. At one end the doors open into a similar corridor, where rockwork is planted with Ferns and Begonias, and the effect relieved with *Cattleyas*, *Cymbidiums*, and other Orchids, also *Anthuriums* in flower. The intention is to arrange the *Cattleyas* in houses in the sequence in which they generally flower, viz., *C. Trianaei*, *C. Mendeli*, *C. Mossiæ*, *C. Gaskelliana*, and *C. labiata*. *C. Mendeli* was bearing a good show of bloom, and Messrs. Low have a fine lot of plants, many of them large enough to be described as specimens. One of these bore eighteen flowers, and made a fine effect. Plants of *Oncidium* species and *Cattleya aurea* were suspended in these houses. Several of the forms of *C. Mendeli* are very attractive.

AN UNUSUALLY-CONSTRUCTED HOUSE.

Beyond this block there is another in course of building, also intended for *Cattleyas*, which will present, when finished, a decided departure from common practice in several features, though there will be some similarity between it and certain continental structures. It will consist of several divisions, and the doors and pathways will be under the eaves of the spans, and the 7-feet stages will extend from eave to eave, under the ridges. This step has been taken owing to Mr. Low's conviction that in the reverse method of arrangement the Orchids are given a second position, the best being occupied by the paths. It is evident that Mr. Low does not fear to place his *Cattleyas* at some distance from the glass, for his system secures the highest part of the house for the plants, and in this case the house is rather high for an Orchid structure, the ridges being 10 feet from the ground. If this does not prejudicially affect the plants, in all other respects they will have the best of it.

Remarked Mr. Low, "I do not believe in such low Orchid-houses; I think that, like human beings, plants want more head-room, and a greater amount of air in the house than they sometimes obtain." This house, with its divisions, is 150 feet long by 60 feet wide. At present the plants which are destined to fill this new structure, are in seven long span-roofed houses of the class usually filled with Palms. A fine lot of plants these are, and, together with a house of large-sized *Lælias*, will give a good account of themselves in the new house, the height of which will, to some extent, tend to make the plants appear smaller than they are. In the centre of one of the houses was a group of tiny plants of various species, every piece, as Mr. Low remarked, having a "past," and adding, "I trust they will have a future too." *Lælia præstans* (Vine House variety), *Dendrobium Harrisonianum* album, *Cattleya Wagneri*, the best piece extant of *C. Mossiæ Arnoldiana*, also the true *C. Reineckiana*, *C. chocoensis* alba; also a white *labiata* with crimson-streaked lip, and others were remarked.

A story as to how this was acquired, that propagated, and the other saved during a crisis, we listened to with much interest, but these items cannot be reproduced here. Suffice it to say that the hopes, disappointments, surprises, achievements, and failures, constitute the experience of an Orchid-grower's daily life.

OTHER PLANTS IN HOUSES.

Having inspected the arrangements being made for the Clapton Orchids, a hurried glance was taken through the rest of the houses. An enormous number of plants are cultivated, and many of them are supplied almost exclusively to the trade. There were large stocks of the following: Hard-wooded plants, including a fine lot of *Acacias* and greenhouse *Rhododendrons*, *Pelargoniums*, Palms, stove climbers, and stove plants generally; *Cyclamens* just raised from seed, *Richardias*, Ferns, Roses (an enormous number in pots), Figs, Vines, *Hydrangeas*, *Carnations*, *Marguerites*, *Gardenias*, &c.

In several of the houses the side stages contained a layer of peat, and the Palms were planted out. These had been removed from 3-inch

FIG. 130.—*DENDROBIUM NOBILE*, AT COOMBE HOUSE, CROYDON. (SEE P. 340.)

blotch below. But in the absence of names, it would be useless to describe the varieties, just as it would be in the case of a group of *Azaleas*. In the majority of instances, of course, the plants are now flowering for the first time, and as a collection they are showing very satisfactorily. The Orchid-grower is seriously upset occasionally when seeking to apply this or that theory to actual practice. Here, for instance, was a plant of *O. crispum*, with very high-coloured leaves streaked with deep red, and distinct looking pseudo-bulbs. Said Mr. Low "We have had a job to keep that plant; most people who have seen it have wanted to purchase it, but it looked so much like a new type—perhaps with red or crimson flowers—that we determined to hold it." The plant is in flower now, and Mr. Low realises that it must be sold for very many less guineas than were offered for it. What are the flowers like? They are equal to those of a fine form, but there is no new type. Indeed, instead of the rich colouring that specialists thought they saw in the leaves, the variety is one of the paler coloured

Venus, *Doris*, *Apollo*, &c., and many others of rarity and value were noticed.

From this house we gain the one devoted to the growth of *Phalænopsis*, and it is no small cause for satisfaction that such a large number of these delicate plants has been safely moved from Clapton during the winter, and placed into a new house without any appreciable injury or even check. Most of the plants have been re-basketed since their removal, and they have made fresh roots and taken hold of the baskets in such a manner as to give excellent hope for the future. This is a wide house with stages running across the width like desks in a school. There are two stages or shelves in all these Orchid-houses, the first a solid one, which prevents the heat arising to the roots of the plants, and generally covered with shingle, moss, or other moisture-retaining material, and over this a lath shelf upon which the plants are placed. We should mention here a few very healthy plants of *Miltonia Roezli*, a species far too seldom seen in good condition.

pots, and would be allowed to remain in the beds for several months. During that time, said Mr. Low, they make extraordinary progress, not so much in height, but they form a bushy habit and make a bigger, better collar, thus laying the foundation for a much stronger constitution than those possess that have always been kept in pots.

ELMHURST, READING.

THIS charming place, the residence of Geo. W. Palmer, Esq., the senior partner in the well-known firm of Huntley & Palmer, occupies a pleasant position on the high ground on the south side of Reading, from which commanding views are obtained of an extensive stretch of country lying beyond the Thames on the Oxfordshire side. The residence and grounds are somewhat circumscribed in extent, but they are in harmony with the surroundings; the lawn and pleasure-grounds are well furnished with deciduous trees and shrubs, while there are sufficient evergreens to impart a furnished appearance to the place during winter.

A winding piece of rockwork afforded recently a cheering display of many hardy spring-flowers; the blue of Forget-me-not, and the violet of Aubrietia, blended with the white of Arabis, and the yellow of Alyssum; in addition there are spring-flowering bulbs, and other subjects. This spot is pleasantly cool in summer, while enough light falls upon the rockwork to enable many summer-blooming plants to flower well. Fringing a shubbery-border close by is a long serpentine line of Dean's coloured Primroses, which have bloomed abundantly, and since the rains came have developed into enormous tufts.

Roses under glass are largely grown, for at Elmhurst they are favourite flowers indoors and out. Plants under glass are in good health, and flowering freely. In a pit of specimen plants of pot Roses could be seen a very handsome foliage sport, the leaves being bordered with yellow, which it is Mr. Dockerill's intention to propagate.

In the plant-houses, decorative plants are largely grown. Crotons, Dracenas, Palms, Caladiums, Aralias, &c., with many flowering subjects, are constantly being produced for service at home and in London.

Melons are a leading feature; a house in full fruiting is a fine sight; there are several leading varieties in excellent character, and the gardener, Mr. Dockerill, calculates upon taking a second crop by extending the leaders to the apex of the house. There are succession-houses also, and in summer some of the Darlington frames now filled with specimen Roses, are also utilised for Melons, and though dependence has to be placed upon solar heat, capital crops are produced. Reading can boast of a number of charming private gardens, and Elmhurst ranks high amongst them. R. D.

BELGIUM.

VISIT TO M. F. PAUWELS' ESTABLISHMENT.

I LATELY passed through the houses of M. Florent Pauwels' Establishment at Deurne, near Antwerp, and noted a fine plant of *Epidendrum vitellinum majus*, 18 inches across, with more than thirty racemes. Also other good varieties of this Orchid. I saw further, *Odontoglossum Reichenheimi*, with two flower-stems bearing seventy-five blooms; good varieties of *O. cordatum*; *Miltonia Roezli alba*, with six racemes, bearing buds and seven flowers; *Schomburgkia tibicinis*, with a flower-stem 4 feet long, with fourteen flowers and four buds in a splendid cluster; *Colax jugosus*, a gem; *Calanthe veratrifolia*; *Cattleya Mendeli*, and *C. Schilleriana*; *Lælia purpurata*, with pure white flowers and a fine lip; *Phalænopsis Schilleriana*, *P. leucorhoda*, *P. rosea*, *P. amabilis* with large flowers, and other Orchids.

Anthurium Andreanum, grown from seed, is admirable for its large and splendidly coloured spathe. Crotons here develop good and richly-coloured foliage, *Nepenthes Mastersiana* × bears numerous pitchers, one a foot long. M. Pauwels has a fine collection of tree Pæonies, some which are now in flower. I would

mention P. Leopoldi, Mme. de Vetry, Casse, Mariane de l'Inaine, and *Pæonia tenuifolia flore pleno*. A pretty little plant is *Dodecatheon Lemoinei robustum* from *D. integrifolium* × *D. Meadia leucifolium*, obtained in 1889 by MM. Lemoine & Fils of Nancy. Ch. De Bosschere.

ANTWERP ROYAL HORTICULTURAL SOCIETY.

This Society proposes, under the presidency of Baron Ed. Osy, of Zegwaart, to organise, during next April, a special horticultural exhibition in the hall of the Antwerp Royal Zoological Society. This show is intended to commemorate the three hundredth anniversary of the birth of the painter A. Van Dyck, who was born at Antwerp, March 22, 1599. The organisers intend that the whole exhibition shall be marked by a strong artistic element. The programme of the exhibition will shortly appear, and will be sent to anyone sending a stamped application to the Society's Secretary, M. Anatole de Cock, 215, Chaussée de Malines, Antwerp.

THE WEEK'S WORK.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Cucumbers for Pickling.—Select the warmest available position for this crop, and plant them on beds or ridges, prepared as directed in this column last month, in groups of three plants, placed 18 inches apart from each other; or they may be put in one line 4 feet from plant to plant, in rich, light soil. The plants require shade from the sun until they have become established. This may be done by placing large flower-pots over them during the hottest part of the day, and the pots may be used at night also as protection against cold. Frequent waterings and syringings are necessary on dry and warm days, especially so as the plants advance in growth.

Leeks.—The land for this crop should be made rich by liberal dressings of manure. Draw the plants from the seed-bed, and transplant them at distances of 9 inches from plant to plant, and 15 inches between the rows. Make the holes with a dibber 6 inches deep, and do not press any soil tightly about their stems, but drop the plant into the hole, and let a little soil fall on the roots of the plants, just enough to cover the roots. Encourage the growth of Leek-plants required for exhibition by frequently stirring the soil, and giving light dressings of soot and artificial manure, being careful not to overwater them until they are in active growth.

Forced Vegetables.—More air should now be admitted to the pits and frames in which early Carrots, Kidney Beans, Vegetable Marrows, Lettuces, and Radishes are growing. They will require frequent attention to watering and syringing. Make another sowing of French Beans in pits which have been emptied of early Potatoes, and make use of all nearly-spent hot-beds for forwarding Lettuces, Radishes, Mustard and Cress, and Vegetable Marrow plants.

General Work.—Support with stakes any crops that require it, and keep the hoe freely in use in all parts of the kitchen garden. Remove weeds from garden walks, and use the roller on them when they are damp or wet. Endeavour to obtain everything in order for the season by clearing up manure and rubbish-heaps, and digging-in all decayed vegetable matter before hot weather causes it to become a nuisance.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Camellias.—Plants that flowered early will by this date have completed their growth; and in order to prevent a second growth, and to allow the shoots to mature and flower-buds to form, the general surroundings should be drier, but not dry, and as much direct sunshine admitted as the plants will bear without browning or discolouring the leaves. If the plants are in a house facing north, no shading at any part of the day is needed, but in sunny houses a thin scrim shade is usually found useful excepting in old-fashioned houses with small panes of glass. The late-flowered plants will scarcely have finished growing, and should be well syringed daily, night and morning, and encouraged by a humid atmosphere being maintained. Whether in active growth or not, care must be taken that the plants do not suffer from lack of moisture in the soil. When the flower-buds are forming on Camellias, the portable plants may in the middle of the present month be stood out-of-doors in a partially-shaded spot, taking care that the

worms cannot get into the pots, and means should be taken to shade the pots from hot sunshine.

Azaleas.—Those plants which finished their growth in heat may be removed to an airy greenhouse, and afforded a slight amount of shade during the hottest hours. If convenient, it is advantageous to keep the plants under glass, it being then easier to control the degree of temperature and the amount of moisture the plants receive. Should it, however, be necessary to place the plants outdoors, this must not be done before they are hardened off, and the place occupied by the plants during the summer months should be partially shaded from the sun, and the pots plunged in coal-ashes or screened by pieces of cork, &c. Those Azaleas which flowered late should be kept in a warm moist house. Thrips often infest Azaleas, disfiguring the foliage and causing it to drop, and spoiling the growth. The best remedy is Richards' XL All, following its use with vigorous syringing.

Ericas.—When it is necessary to retard any of these plants, stand them outside and protect from bright sunshine, placing frame-lights over them, so as to throw off the rain, taking the utmost care that the soil does not become dry. Ericas which are growing should be lightly shaded during the hottest part of the day, and the base upon which the pots stand kept in a moist state. Any shoots which seem to be growing at the expense of others on the same plant should have the point pinched out, or be drawn down towards the rim of the pots.

Epacrises.—Those plants which flowered earliest will now be growing freely, and should be shaded when the sunshine is very ardent; and as the plants fail to flower satisfactorily if the shoots are drawn by over-shading, the latter must be studiously avoided, and plenty of air afforded the plants by day, and some also at night, the plants being syringed once or twice daily, according to the weather. When a plant requires water, afford it liberally, but avoid either extreme. Plants which flowered late will now be growing freely, and any repotting that may be necessary should be carried out. The best kind of compost consists of good, hard peat and sand; the pots should be clean or new ones; the crocking should be efficient and abundant, and consist of a lower layer of big crocks, and an upper one of fine ones. In repotting, the roots at the sides of the ball should not be much disturbed, and if the crocks are embedded, leave them alone; do not give large shifts or use sifted soil, but take it as it comes, and work it down between the pot sides and the ball with a thin potting-stick, making it firm as the filling proceeds, and finish off smoothly with a slight inclination from the sides to the centre, that part of the ball always having a tendency to become dry, and thus causes the death of the roots thereabouts. Let the space left for receiving water be ample in each case. Never afford water after the first application on repotting them without first tapping the pots to ascertain their condition. Growing plants should be syringed early in the morning. Epacrises grow admirably in deep cold frames, resting on coal-ashes, and after growth is finished, unless the plants are very small, they may be plunged in coal-ashes out-of-doors.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Shrubs recently planted.—Shrubs of most species which were planted during the winter, will benefit by having the soil frequently hoed round about and among them, not only for the destruction of weeds, but to aerate the soil. The late rains have been of great benefit to these plants, but the cold experienced at night renders growth very slow; and the season which at one time promised to be an early one, will be very backward.

Bulbs.—Such of these as have been used in spring flower gardens, must in most cases now be lifted to make room for the summer bedders. When the bulbs are lifted, lay them out singly in a shed, provided they are ripe, to dry, afterwards storing them in sand till required again for planting.

Perennial plants.—Aubrietias, Alyssum saxatile, Bellis perennis, Phlox reptans and other dwarf species, and Iberis sempervirens, as the plants are lifted they should be divided if an increase be desired, and replanted in lines at 1 foot apart in the reserve garden. Myosotis in variety, Silene pendula, and Wallflowers should not be kept unless the latter be double-flowered; seedlings affording more satisfactory results.

Statice Suworowi.—For planting in the front of borders of herbaceous perennials this Statice is a very suitable plant, the best perhaps of all the annual Statice. The flower-spikes, which are branching,

are of a bright-rose colour, and several are borne on a plant, stand well above the foliage, in fact the foliage is of very small size in comparison with the flower-spike, which grows to the height of 1 foot. The plant continues in bloom for a considerable period of time, as each spike will last in flower for several weeks. The spikes also last when cut for a long time. It is a hardy annual worthy of general cultivation.

Bedding-out.—All Asters, Antirrhinums, Petunias, Marigolds, Pyrethrums, Golden Feathers, Lobelias, Stocks, and Zinnias, should be planted out without further delay, but it may be prudent to wait a few days longer before planting out the more tender subjects, or till the weather takes a favourable turn.

General Remarks.—Sweet Peas, when 3 or 4 inches high, should be moulded-up, and provided with neat, well-feathered boughs of the same height as that to which the plants are likely to attain. The soil alongside the rows or circles should be loosened. Lilies of all kinds, as growth proceeds, should be neatly staked, especially *L. candidum*, *auratum*, *croceum*, and *longiflorum*, as should *Pæonies*. Pentstemons which have been raised from seed may now be planted where they are intended to flower, the soil being first liberally manured. The seedlings of annuals sown last month should be well thinned-out, in accordance with the requirements of each. Newly-turfed lawns will require abundant rolling, and croquet and tennis-grounds should have similar attention, and the spudding-out of deep-rooting weeds, Daisies, &c., performed.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

The East Indian House.—Species of *Aërides*, *Saccolabium*, *Angraecum*, *Sarcanthus*, *Vanda*, and others, that are potted in crocks and surfaced with sphagnum-moss, must be watered with much care now that they are making growth. It is necessary to afford just sufficient water only to keep the moss in a state of healthy growth. The roots inside the pot or basket will quickly decay if the material be kept constantly saturated. The plants are now developing large, fleshy, aerial roots, and these should be examined occasionally, with a view to guiding them down into the compost. The old roots that are long enough should be carefully pegged down on the surface, and the young roots will then the better enter the moss. These aerial-rooting species require an evenly humid atmosphere, but if grown in a too high temperature and a saturated atmosphere, with insufficient light and air, their foliage will become spotted and unhealthy. Those who have seen the remarkable new *Eulophiella Peetersiana*—figured in the *Gardeners' Chronicle* on April 2, 1898—in bloom, consider it to be one of the most beautiful of Orchids. When its cultural requirements are properly understood, and the plant has become established, it will be much sought after for exhibition purposes and for floral arrangements. We may yet learn something more of its requirements, but my present experience shows it to be tolerably easy of cultivation if treated with ordinary discretion. Immediately the imported pieces arrive they should be placed in pots, and firmly fixed with clean crocks and charcoal, then stood upon the stage in a *Cattleya-house* temperature, and be kept well supplied with moisture by pouring water through the crocks several times a day, taking care not to wet the bulb or rhizome. The plants will soon commence to grow, and then it will be necessary to afford rooting material. Having a rambling habit, rather large pans or teak-wood baskets are preferable to pots, and these should be large enough to allow the roots to spread freely in all directions. They should be filled to about one-half of their depth with drainage, over this should be placed a layer of sphagnum-moss, and the basket filled nearly up to the rim with peat and moss in about equal parts, mixing with it a moderate quantity of broken crocks. There is no necessity to raise the plant above the rim, but lay it upon the compost, with the base of the young growth just touching the soil. For the first few weeks keep the surface of the compost just moist by sprinkling it occasionally with tepid rain-water, but allow no water to fall on the plant. When new roots are seen pushing from the rhizome, prick in a few living heads of sphagnum-moss over the surface of the compost, and water more liberally. Place them in a hot moist corner of this house, where they may be conveniently shaded from the sun at all times. During the winter months, when the temperature is low, the plant should be removed to the warmest and driest corner, but it must be kept well watered at the root. To fully explain this, I may mention that at the beginning of the past winter our plant was in

the ordinary plant-stove, where the night temperature frequently fell to 58° and 60°. Very soon the leaves commenced to spot, the plant was therefore immediately removed to another house where the thermometer rarely falls below 65°. The benefit of the higher temperature was soon apparent, for the dangerous spotting was checked, and eventually the plant produced its welcome flower spike.

The Cattleya-house.—*C. gigas* is now showing its flower-buds, and will require to be kept fairly moist at the root, and even those that have failed to produce spikes must receive generous treatment. When the growths have become fully completed, and the spikes are removed, gradually expose the plants to more air and sunshine, because the better they are matured, the more abundant will they bloom next year. *C. Rex*, *C. Dowiana* and its variety *aurea*, should be kept at the warmest end of the house, and be carefully supplied with water until the flowers open. When the growth is fully completed, treat the plants as recommended for *C. gigas*. The best time to afford fresh potting material to these *Cattleyas* is when new roots are seen pushing from the base of the current season's growth.

HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Strawberries.—In the warmer districts early varieties will now require protection for the fruit, and the nets should be placed over the beds before the blackbirds and thrushes get at them, the finest fruits usually colouring first, and being the first to suffer from their attention. Before the nets are put on, the trusses of fruit should be raised on to the mulching, otherwise in wet weather they soon decay; moreover, all large weeds should be pulled up and removed forthwith. It is a saving of time and of the netting if the latter can be suspended or stretched on stakes 6 feet high, with a knob formed of a hayband wound round at the top, the stakes being fixed firmly in the ground at distances of 10 feet, and the net fixed at the sides with wooden pegs. With nets fixed in this manner, the fruits can be gathered without disturbing the net except at one end of the bed. Sometimes a border skirting a wall may be covered by means of nets fixed to the top of the wall, and to a row of stakes placed next to the walk. Late Strawberries, or those wanted for special purposes, should have the smallest berries removed, and be afforded diluted liquid-manure, applied to the soil without letting any of it come in contact with the leaves or fruits, applying it twice or thrice a week till the fruits begin to colour. In order to obtain strong runners, healthy young plants must be selected, the fruit trusses removed, and encouraged to grow vigorously by applying liquid manure in dry weather. By following this method, extra strong plants can be obtained that will afford large fruits the following season, but there must be no delay in layering the runners, and in planting them as soon as they are well rooted.

Bush Fruit.—Let close attention be paid to the clearing of the Gooseberry bushes of the larvae of the Gooseberry saw-fly, either by means of the garden-hose or engine, by dusting with Hellebore-powder, or by hand-picking; and later on, remove the soil under such bushes as were infested, and replace it with fresh from a distant quarter of the garden. Failure to do this will result in an attack next year. The Black Currant-mite is troublesome in some gardens, and all affected shoots or the tips of them, should be cut off and burnt forthwith.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Melons.—Make a final sowing, to raise plants for autumn fruiting, and as soon as the seedlings show the first rough leaf, pot them up singly into 2½-inch or 3-inch pots. Remove the points of the leading shoots of plants about to flower as soon as they have furnished the requisite space, and stop the side shoots at two leaves beyond each fruit, all succeeding side shoots being stopped at the first leaf. About noon each day go over the flowers already open, with a view to setting them, and discontinue syringing until a crop of fruits has set, only damping down in the meantime the bare surfaces of the house once on each bright day. When the house has been closed in the afternoon is the best time to do this. The present dull and cold weather obliges us to use more fire-heat than is usual at this date. The temperatures should be 70° by night and 75° by day, with a rise of 10° to 15° from sunheat. Afford ventilation by degrees, first before the temperature exceeds 80°, and again before it rises to 85°. Close the house early each afternoon, and if the temperature

rises to 90° no harm will be done. Plants now swelling fruit require to be liberally watered when the soil shows signs of dryness, and occasionally liquid-manure may be used for the purpose. Checks and cracking to swelling fruits may be caused by allowing the soil to become dry, or by removing too much foliage at one time from the plants. In cases of fruit now colouring, syringing should be discontinued, and more air given. Give just sufficient root-waterings to keep the foliage green and healthy.

Cucumbers.—Plant these out in a house or in frames, as recommended for Melons. Cucumbers require lighter and richer soil, and it may be given in less quantity, so that additions may be made afterwards. That they be given plenty of water and frequent syringings is important, and air should be admitted with care, and when the soil last added is full of roots, another layer of 2 inches deep may be given, using three parts of light loam to one of old Mushroom-bed manure. Afford water liberally whenever the soil shows signs of dryness, with manure added to the water occasionally. Syringe each morning that is bright, and again in the afternoon at shutting up time should the sun be warm. Frequently thin-out the old worn-out wood and leaves, removing surplus young shoots, and stop others at the third leaf.

Tomatos that have been growing in a limited quantity of poor soil to prevent over-luxuriant growth while in flower, and induce the blooms to set, may now, that a crop is set, be given a top-dressing of three-parts loamy pot-soil, and one of old mortar-rubbish, and a little concentrated manure added to it. Plants that have grown to the limit of the space allotted to them may be stopped, and attend to the taking off of the side-shoots as frequently as required. Seeds may now be sown to produce plants for autumn and early winter-fruiting. The best variety I know for this purpose is *Conqueror*. Sow the seeds thinly in pots or pans in light soil, and pot them off into 3-inch pots as soon as they have made the first rough leaves. Place them in a cold, freely-ventilated frame or pit, close to the glass, and exposed to the full sun.

THE APIARY.

By EXPERT.

Too many Drones cause Swarming.—They say that when Louis XIV. was contemplating war, his Prime Minister, Colbert, said to him, "Sire, to make war we need, firstly, money; secondly, money; thirdly, money." Well, to raise honey successfully and prevent swarming, we need, firstly, to prevent drone-rearing; secondly, to prevent drone-rearing; and thirdly, to prevent drone-rearing. This is not all we need, as money is not all we need in war; but it is one of the great needs that are too often disregarded. The drones are expensive to the bee-keeper, more so than many believe, and unprofitable and annoying to the bees. They are in the way, being out of the hive a couple of hours each day, get in the path of the bees at the busiest time, and keep the hive hot when it most needs to be cool. One frame full of drone-comb will furnish all the drones that are needed for a full apiary of 100 colonies. The others should be removed from the hives in early spring and replaced by worker-comb. True, some people will tell you that if you remove the drone-comb, the bees will cut down worker-comb and put drone-comb in its place. Do not listen to them. One great drawback to progress lies in the fact that many people go by hearsay and not by their own experiments. Let our readers take out all the drone-comb that they see in all their hives except in one or two of the best colonies (they will be sure to leave small patches of it here and there, but this is unimportant), and they will find it much cheaper than rearing drones and using some queen-trap or other to catch them afterwards. They will also find that their bees will swarm much less, provided they also try to keep the hives well shaded, with enough ventilation to prevent the bees from lying out in the hottest weather, and room enough for the bees to harvest as large a crop as may be expected. We speak of ventilation. Did you ever stop to think that when the bees of a hive are lying out in clusters during a good flow of honey it is because they feel ill at ease inside? This is one reason why we are in favour of loose-bottom boards. We want to be able to raise the hive sufficiently off its bottom to do away with the clusters of bees that lie idle on the outside. We want to give them enough air to enable them to make the whole hive comfortable in any part of it. The fewer drone-traps, queen-excluders, partitions, separators, &c., you have in your hives, the better the bees will feel, and the fewer swarms you will have.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, JUNE 8 { Royal Cornwall Agricultural Society's Show (2 days).
 FRIDAY, JUNE 10—Royal Botanic Society (Lecture).
 SATURDAY, JUNE 11 { Royal Botanic Society, General Meeting.

SALE.

FRIDAY, JUNE 10 { Imported and Established Orchids from various sources at Protheroe and Morris's Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—59.9°.

ACTUAL TEMPERATURES:—

LONDON.—June 1 (6 P.M.): Max., 58°; Min., 43°.

PROVINCES.—June 1 (6 P.M.): Max., 52°, S. W. Ireland and Scotland; Min., 45°, N. E. England.
 Rain, local snowstorms; thunder.

The Temple Show.

WE are glad to learn that the Treasurer is well satisfied with the financial results, so far as they are yet known. The deepest concern, however, is felt at the loss of the valuable collection of Orchids exhibited by M. JULES HYE, of Ghent. The loss would have been serious enough had it befallen a fellow-countryman, but that it should have occurred to a distinguished foreigner, a member of a society which recently received us at Ghent with such cordial and splendid hospitality, causes the greatest distress. It appears that about 9 P.M. on Friday evening, when exhibitors were packing up and removing their plants, Mr. HYE's plants were seen by Mr. HYE's assistant, as well as by the society's superintendent. Mr. HYE's custodian then left the tent, and on his return about 10 P.M. the Orchids were missing. The plants included the very rare *Odontoglossum luteo-Vuystekeanum*, and three other rare *Odontoglossums*; *Lælia Latona*, *Lælio-Cattleya* hybrid (*C. Lawrenceana* × *L. cinnabarina*), and *Miltoniopsis Bleuana rosea*. Telegraphic enquiries were made to other exhibitors under the impression that they might have been packed up by accident with some other collection, but up to this time nothing has been heard of the missing plants, for the return of which a reward is offered in our advertising columns.

Baseless surmise is worse than useless. The calamity is evidently mainly attributable to the exhibitor himself, who left his plants unguarded three or four hours after the show had closed. The Society is thus free from all responsibility in a technical sense; how far it can be absolved morally remains to be seen. All we know is, that the loss is felt as a public disgrace, and the more keenly in the circumstances we have mentioned. Let us hope that the affair may prove to have been accidental.

We have received the following letter concerning the matter from Messrs. JAMES VEITCH & SONS, and refer our readers to our advertising columns, where a reward is offered for the recovery of the plants:—

"At the Temple Show, M. JULES HYE, of Ghent, lost the very valuable Orchids he exhibited, and no trace can be ascertained of their whereabouts. They were seen by him in the tent soon after 9 P.M. on the Friday, but they had disappeared by 10 o'clock, and he is naturally in great distress. Would you make this great loss known through your columns in this week's issue."

In connection with this exhibition, we give in this issue three views of groups taken in the tents, which were sufficiently described in our last issue. Numerous new and interesting plants were also figured in that number.

Cocoa.

THE extensive culture of Cocoa (*Theobroma*) in Ceylon, is being seriously interfered with by the attack of a canker which greatly reduces the yield. The planters, remembering the calamity that befell the Coffee, were alarmed for the future of the Cocoa cultivation; they submitted a statement to the Governor, and sought the assistance of the Colonial Office at home in investigating the cause and possible cure of the canker. Government help being refused, the planters themselves resolved to undertake the inquiry, and engaged Mr. J. B. CARRUTHERS to visit Ceylon. Mr. CARRUTHERS had previously paid considerable attention to the disease of the Larch and other trees, and was acquainted with the requisite methods of investigation, and the conditions under which the parasitic fungi attack trees. He arrived in Ceylon after the middle of December, before the close of the rainy season. He at once proceeded to study the affected trees, and, after three months' close microscopic investigation, he has submitted to the Planters' Association an interesting interim report.

He has determined that the roots and the foliage are free from disease, but that the trunk and the fruit have been attacked by two different fungi, the mycelium of which abounds in the diseased parts. He has separated the accidental fungi that were found on the injured portions. Having obtained the fructification of the species connected with the disease, he has been able to determine their affinities. He has made cultures of them, and from these cultures he has produced the diseases in the stem and on the pod, thus conclusively proving them to be the cause of the diseases. He is continuing to work at the life-history of the two fungi, and to make experiments, with the view of determining how far it may be possible to improve the conditions of culture, or by applications to prevent the germination of the spores in the hope that the injuries caused by these fungi may be reduced, if they cannot be altogether remedied.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The Fifty-ninth Anniversary Festival Dinner of this Institution will be held on Wednesday next, June 8, at the Hôtel Métropole, when we hope the supporters of this deserving charity will muster in strong force. The DEAN OF ROCHESTER—that well-known horticultural enthusiast—has intimated his intention to attend, and those of our readers who desire to be present on this occasion should communicate with the Secretary, at 50, Parliament Street, W., without delay.

ROYAL GARDENERS' ORPHAN FUND, MAY 26.—A meeting of the Committee was held this day, when the following special receipts were reported:—His Grace the Duke of Rutland, per Mr. Divers, £5; Sir R. Hargreaves Rogers, £5 5s.; Mr. Witty, Nunhead Cemetery, £1 15s. 6d.; Francis Robinson, £1; the Hugh Low Cricket Club, sale of Bats, Balls, &c., £3 7s.; receipts, sale of gold ring, received from an anonymous lover of flowers, £1 6s.

THE MARKET GARDENERS', NURSERYMEN, AND FARMERS' ASSOCIATION.—Agricultural Rates Act, 1896. Rating of Glasshouses: SMITH AND OTHERS v. RICHMOND. A second list of sums paid or promised, amounting to £43 19s., in aid of Fund for Appeal to House of Lords has been received. The Association has determined to proceed with the Appeal, although the response to the application for funds has not been so general as the importance of the matter demands. Assistance is solicited from the numerous growers who have not yet contributed.—GEORGE MONRO, Hon. Treasurer, 32, King Street, Covent Garden, W.C.

"THE FRUIT-GROWERS' ANNUAL."—The subtitle of this book is the "Market-gardeners' Guide," and the editor is Mr. SAMPSON MORGAN, who has had twenty years' experience of the wholesale fruit markets; the reliability of the information given can therefore be depended upon. The articles included deal with such topics as:—Chrysanthemum Notes, Science Apple-culture, Foreign and Colonial Mails, Fruit Charts, Strawberry Culture, Shows for the Year, Peas June to November, Railway Rates, Channel Island Rates, Imports and Exports for the Year, Fruit-growing Movement, Men of the Market, Injurious Insects, Forced Strawberries, and various biographical notices of well-known growers and salesmen. It may be had from LITTLE & SON, 3, St. Bride Street.

CEARA RUBBER.—The article on this subject in the last number of the *Kew Bulletin*, n. 133, p. 1, will be read with much interest by tropical planters, as the tree *Manihot Glaziovii* is easily propagated by seeds or by cuttings, is very hardy, a fast grower, not subject to insect or fungus attack, and thrives on poor soil. It produces rubber of good quality, for which there is a large demand, and it is, therefore, recommended that the tree be planted over large areas in a dry climate and on poor stony soil.

BLACK ROSES.—The St. Petersburg *Novosti* states that Mr. FETISOFF, an amateur botanist in Voronezh has succeeded after ten years' persistent experiments, in cultivating Roses of a pure black colour. These new black Roses, it is further stated, will be exhibited shortly in London.

FLORA OF MONGOLIA.—Mrs. LITLEDALE, in a recent journey through Siberia to North Western Mongolia, made an excellent collection of dried plants, which have been presented to Kew. The *Bulletin* speaks of them as admirably prepared.

MR. GLADSTONE AND CLUMBER.—When this great estate of the Clinton family was passing through the throes of a severe financial ordeal a good many years ago, Mr. GLADSTONE was one of the trustees, who finally brought Clumber safely out of the fire, and freed it for the benefit of present owners. During a portion of that period of depression Mr. MILLER, now of Ruxley Lodge, Esher, was gardener at Clumber, and thus he became very familiar with the late great statesman. He tells of one visit of Mr. GLADSTONE and a fellow trustee with the agent to the estate. Mr. MILLER was then engaged in blasting with dynamite old tree-stumps or roots left in the ground. The process was new to the statesman, and a charge was exploded in his presence. Mr. MILLER placed his visitors at a safe distance from the scene of operation, but not before they had seen the process of boring a deep hole in the bole with an auger, then charging it with the dynamite obtained from the estate collieries, and firing the fuse with the aid of a percussion-cap. "How do you, after firing the fuse, succeed in getting out of danger?" said Mr. GLADSTONE. "You will see, sir," said Mr. MILLER, having put the visitors at a safe distance, the point of the fuse was ignited, which at once began to hiss loudly, and the operator ran. The charge exploded in 1½ minutes, so that 100 yards was easily placed between the source of danger and the operator. In this case the root was not only lifted clean out of the ground, but was riven into several pieces. Sometimes, if the charge be very heavy, the boles are torn into thousands of tiny strips. On another occasion Mr. GLADSTONE took great interest in the transplanting of very large Yew trees on the estate, with the aid of a "Barron" machine; and on another visit, when he found Mr. MILLER pruning wall trees, remarked that it was not such hard work as tree-felling, to which the gardener rejoined, perhaps not, but it was a good deal more meritorious.

PELICANS.—The Royal Gardens, Kew, have been supplied with six pelicans by Admiral BLOMFIELD, as we learn from the *Kew Bulletin*. It is to be hoped the birds will not be, like their predecessor, shot by ignorant gamekeepers.

FIG. 131.—GROUP OF PHYLLOCACTUS EXHIBITED BY MESSRS. J. VEITCH AND SONS AT THE TEMPLE SHOW.

FIG. 132.—GROUP OF HARDY FLOWERING PLANTS, ETC, EXHIBITED BY MESSRS. J. VEITCH AND SONS AT THE TEMPLE SHOW.

GREENWICH PARK AND KEW GARDENS.—By order of the First Commissioner of Works, in accordance with the commands of Her Majesty the QUEEN, the grounds of the Ranger's Lodge at Greenwich and the Royal Palace at Kew will henceforward be opened to the public; and the grounds of the QUEEN'S Cottage at Kew were on Saturday, May 21, formally added to Kew Gardens.

JUGLANS REGIA VAR. RUBRA.—The May number of the *Wiener Illustrirte Garten Zeitung* contains a coloured plate of a flowering shoot, mature leaf, and a nut in three positions, one of which shows the currant-red skinned kernel. It was first mentioned by JOHANN HERMANN KNOOP in his work *Fructologia of Beschryving der Vrugtbomen en Vrugten, &c.*, Senwarden in 1763. The variety has almost disappeared from European cultivation, and is probably only now to be found in the southern parts of the Austrian Empire, and in Slavonia. It is a comparatively small tree, soon coming into bearing; but not so hardy as the commoner Walnuts, and to this circumstance is due the fact of its general disappearance. For the milder parts of Britain this variety should be found well suited, and should it be found persistently spring tender, as is also the type, there is still the reddish-green foliage to recommend it as a picture tree.

ANOTHER FIRE IN SCOTLAND.—We regret to hear that the well-known establishment of Messrs. DRUMMOND & SON, seedsmen, Stirling, was destroyed by fire on the 29th ult. The damage is estimated at £10,000.

ERITRICHUM NANUM.—M. H. CORREVEON writes from the Geneva Jardin Alpin d'Acclimatation as follows:—"I send you with this a plant of *Eritrichium nanum*, the buds of which are beginning to expand. It is taken haphazard from a border where now are flowering as well as if among the high Alps, *Androsace glacialis*, *A. Charpentieri*, *A. pyrenaica*, *A. imbricata*, *A. pubescens*, *A. helvetica*, *Petrocallis pyrenaica*, and the *Eritrichium*. As you may see, the plant is young, vigorous, and covered with buds. The foliage retains the characteristics of that of plants from high elevations; it is quite as downy, and not increased in size. The flowers remain quite sessile, which is a peculiarity to be especially noted. Rock plants from high altitudes are characterised by having quite stemless flowers. This gives beauty to clumps of *Androsace*, *Saxifraga*, *Draba*, &c., whose stems, closely packed together, form a round ball absolutely covered with flowers, so that beneath this cloud of brilliant blossoms the foliage is not to be seen. To preserve this low and flower-covered form is the desire of the alpine gardener. For more than fifteen years I sought the secret of so doing, and in 1896 I for the first time discovered it. The *Eritrichium* which I send, a two-year-old seedling, will prove to you that I have been successful. Briefly stated, what I have found is, that the plants from the higher Alps suffer, with us, from over-nutrition, owing to the richness of the soil which is far too nourishing for them. *Eritrichium*—this I mention because I have forwarded the plant, but I could find other examples—is more beautiful and flowers better when growing in a soil poor in nutritive matters. In the debris of rocks, in the fine sand of the moraines, or in fissures of the rocks, these plants do best. We therefore sowed the *Eritrichium* seeds in sand, with a very little peat and sifted sphagnum, and pricked them out into a soil still lighter, but mixed with crushed pebbles. In the autumn we set them in granitic sand and left them to pass the winter dry, never giving water. They then lost the appearance of living plants, and were as if dried. But the centre of the clumps are now green and flourishing. In early spring we transplanted them to rather larger pots, half filled with drainage, and for the rest, with light soil, half sand, half peat. The surface of the pot was covered with broken pebbles, and the plants exposed to sunshine and damp. They grew rapidly green, and soon were covered with buds, well preserving the characteristics of the species. We anticipated the flowering season by four months, as it is not until August that *Eritrichium* and the majority of plants now flowering in

the frame bloom under natural conditions, where also they are, for three months at least, covered with snow." The plant sent is a little gem, in a very healthy state, and uninjured by its long transit in a close wooden box.

ROBERT BROWN.—The Bentham Trustees have, as we are told in the *Kew Bulletin*, presented to the collection of portraits, one of the great botanists painted for LADY FRANKLIN about 1856.

SUGGESTIONS FOR THE MANURING OF VARIOUS CROPS.—Peas and Beans are leguminous crops, with which are included Vetches, Clovers, Sainfoin, and Lucerne. These do not require nitrogenous manures, as, by means of the "nodules" present on their roots, they have the power of making use of the free nitrogen of the air as plant-food. Manures, therefore, like nitrate of soda and sulphate of ammonia, are not required for these crops; phosphates and potash, however, especially the latter, are of considerable service. Lime also is generally beneficial, and farmyard manure is always valuable. A useful dressing per acre for Beans or Peas might be—10 to 15 tons farmyard manure 3 cwt. kainit, 2 cwt. superphosphate. Where the soil is heavy and rather damp, and especially if it is poor in lime, 4 cwt. basic slag per acre might be advantageously substituted for 2 cwt. superphosphate. Swedes, Turnips, and Rape are generally most benefited by an application of phosphatic manures. The following may be a useful dressing per acre:—Ten to 15 tons farmyard manure, 2½ to 4 cwt. superphosphate. If no farmyard manure is applied, the quantity of superphosphate may be slightly increased, and either 1 cwt. nitrate of soda as a top-dressing, or 2 cwt. dried blood at the time of sowing would be a useful addition. Basic slag may be substituted for superphosphate on damper soils, which are deficient in lime; on light soils 1 to 2 cwt. kainit per acre is a useful addition to the above manures. The farmyard manure may be applied during the previous autumn or winter, or at the time of sowing; the phosphatic manures preferably at the time of sowing, and the kainit in early winter. Swedes and Turnips do not respond so well to liberal manuring in the south and south-east of England as they do in the north and north-west. Cabbages do well with a liberal application of farmyard manure. The following is a useful dressing per acre:—Fifteen to 25 tons farmyard manure, 2 cwt. nitrate of soda, 3 cwt. superphosphate, 2 cwt. kainit. *Fourth Annual Report on Field Experiments, University Extension College, Reading (Douglas A. Gilchrist).*

PRESENTATION.—After 12 years faithful service, Mr. J. GRAY, head gardener at Bodorgan, Anglesea, severed his connection with that place a fortnight ago. Before leaving, Mr. F. WALTON, the foreman in the gardens, on behalf of himself and others who had served under Mr. GRAY, presented him with a case of handsome carvers, bearing the following inscription:—"Presented to Mr. J. GRAY, as a token of respect, by the assistant gardeners of Bodorgan upon his leaving Bodorgan, Anglesea, North Wales, May, 1898."

TOOGOOD'S "CALENDAR OF SOWING AND PLANTING."—We will not say that this little publication is too good, but it is assuredly very useful for amateurs, whilst professional gardeners will be glad to possess it for purposes of reference. It may be had from Messrs. TOOGOOD & SONS, of Southampton.

"GULF OF BOTHNIA" S.S. WITH FRUIT FROM THE ANTIPODES.—This ship entered Victoria Docks, London, on May 16. She brought 7000 cases of Apples from Tasmania; also 1545 cases of Apples from Australia. Part of the latter came by "new experiment" in cool storage, and turned out rather unsatisfactory.

ST. PETERSBURG HORTICULTURAL EXHIBITION.—The Imperial Horticultural Society of St. Petersburg will hold an international exhibition next year, under the patronage of the EMPEROR. The exhibition will be divided into two sections—a flower

and plant show, open from May 17, 1899, for ten days, and an autumn fruit show, to be held for an equally long period. The exhibition will be located in the Tauride Palace and the celebrated garden around it, which will be specially arranged for the purpose.

SIR THOMAS DYKE ACLAND, BART.—The announcement of the death of this venerated country gentleman on the 29th ult. will be received with great regret, though, from the efflux of time, the event was not unlooked for. The deceased gentleman was a scholar, but by no means one of narrow sympathies; on the contrary, the catholicity of his views and the versatility of his powers were remarkable. He was educated at Christchurch, Oxford, with GLADSTONE, a kindred spirit, with whom a close friendship existed to the last, and attained the honour of a Double-first. He took a great part in agricultural matters, and was ever to the fore in questions of education and healthy progress. He was an occasional correspondent of the *Gardeners' Chronicle*. At Killerton was raised from cones produced in this country the first seedling Deodar. This plant was transferred to Kew, where it now forms a fine tree.

"HOOKER'S ICONES PLANTARUM."—The last-issued part, dated April, 1898, contains numerous descriptions and illustrations, mostly of plants of botanical interest only. Some of the plates were destroyed in a fire that occurred at the lithographers, but they will be reproduced in a later part. *Passiflora fuchsiflora*, Hemsley, is a species from British Guiana, which it would be desirable to introduce into British gardens. The *Passifloras* of this region need revision, as so many new forms have been discovered of late years. *Tachadenus elatus*, Hemsley, is a *Gentianad*, with very long corolla-tube and spreading limb, which it would be also desirable to introduce if we could grow it when we had it!

REPORT OF FIELD EXPERIMENTS AT READING UNIVERSITY EXTENSION COLLEGE.—The fourth annual report on field experiments made in connection with the University Extension College, Reading, is now before us, and includes a chronicle of the trials made in Berkshire, Dorsetshire, Hampshire, and Oxfordshire; a summary of general results, papers on manuring of crops, and compositions of foods and feeding stuffs, and notes on manures. The report is published under the authority of Mr. DOUGLAS A. GILCHRIST, Director of the Agricultural Department of the College.

QUARANTINE FOR PLANTS.—Alluding to the steps taken to prevent the intrusion of the San José Scale, our contemporary, *Meehans' Monthly*, has the following wise remarks:—"But the truth is, the Scale does not need looking after—not by law, for the Scale will travel in spite of all law and its useless expenditures. Cultivators should be encouraged to look for and destroy the Scale. It is as sensible to make laws that there should be quarantines against weeds as against insects. Like love, they laugh at locksmiths."

EUCALYPTUS GLOBULUS is in flower in the garden at Huntley, Bishops Teignton, as we learn from the gardener, Mr. BEST. We lately saw two young trees of this species at Buckland, near Dover. One was suffering if not dead, the other was as well as could be expected in the locality.

HOME CORRESPONDENCE.

CULTURE AND VARIATION.—Mr. Druery has referred to one of my books (*Gardeners' Chronicle*, May 21, p. 307), *The Origin of Plant Structures by Self-adaptation to the Environment*, and in comparing definite with indefinite variations has—as it appears to me—missed Darwin's meaning. Prof. Romanes used the word "indiscriminate," but he only meant what Darwin signified by "indefinite." There may be not only 1,119 varieties of wild Ferns but thousands more, but they are not the seedlings of one Fern; but as Mr. Druery says, they are generally found as single individuals, i.e., they are definite variations.

Darwin, in stating what he believed to be the sources of new varieties and their species, refers them to two things: first, individual differences among the plants of the same species. These, however, are quite incapable of giving rise to new varieties, as I have shown elsewhere (*Natural Science*, vol. vi., p. 385, "Individual Variations"); secondly, if a plant migrate, so that it is subjected to the direct action of changed conditions, then he says, "Changed conditions act directly and definitely on the organisation, so that all or nearly all the individuals of the same species thus exposed become modified in the same manner. . . . In most cases, however, of the direct action of changed conditions . . . indefinite modifications are the result" (*An. and Pl., &c.*, ii., p. 418). Unfortunately, he gives no examples, and it is this latter statement that I venture to call in question. That Darwin was perfectly aware of the definite action of changed conditions of life is clear from the above, and several other passages, but he never followed the subject up, and so contents himself with such an observation as the following:—"In separated districts, long-continued ex-

frame in ordinary garden or field-soil, placed within 9 inches of the glass, in the same way as bedding Calceolarias, and treated in like manner during the winter and spring months, receiving plenty of air—in fact, drawing the lights off during the day in mild weather, and affording protection during frost. The best way for "A. E." to proceed with a view to attaining the object in view, is to plant-out the batch of cuttings which he has just struck in the manner described in my note under the heading of "Market-gardening," published in the *Gardeners' Chronicle*, May 14 last, and take the necessary number of cuttings from these plants at the end of the month of June, or early in July, selecting short-jointed cuttings from 2 to 3 inches long for the purpose. These may be dibbled-in 3 inches apart in a frame (improvised or otherwise) under hand-lights, or singly in 3-inch pots, which may be stood close together on coal-ashes in a sheltered position, if a frame is not available having a south or west aspect, shading them for a few hours during the heat of the day, and damping them overhead in the afternoon to freshen up the cuttings, as well as to keep the soil moist

fairly firm. This done, stand the plants on coal-ashes in a shady place, and afford water at the roots. The plants will have established themselves in the pots in a week's time from being potted-up, and should then be subjected to the full sunshine, sprinkling them overhead on bright afternoons for a couple of weeks from the time of potting, whether they occupy a sheltered position out-of-doors or be placed under glass in a cool, airy house. The plants must be kept uniformly moist at the roots from the time they are planted out-of-doors until they have done flowering. An occasional surface-dressing of artificial manure immediately before applying water at the roots will be beneficial. Afford the plants as much light and air as possible, consistent with maintaining a minimum temperature of about 40° during the winter and spring months, and keep all spent flowers (where the latter are not cut in a fresh state) picked off. I am afraid "A. E.'s" "cut-backs" will not turn out satisfactorily; at the same time he will be in a position to compare the results of both methods of procedure. H. W. Ward Rayleigh.

FIG. 133.—GROUP OF ROSES EXHIBITED BY MR. GEORGE MOUNT AT THE TEMPLE SHOW.

posure [to different conditions of life may perhaps produce new races without the aid of selection; but to this difficult subject of the direct action of the conditions of life we shall in a future chapter recur" (*Op. Cit.*, ii., 192); i.e., the passage already quoted. The two results may be thus summarised. If the seedlings of a plant brought under new conditions vary in all directions, then natural selection (in this case the environment) selects one or more best fitted to survive, and destroys all the rest. That is Darwinism; but Darwin gave no facts in support of it. On the other hand, if the seedlings all vary more or less in the same direction towards adaptation, then, as Darwin says, a new species will arrive without the aid of natural selection. This is definite variation, and what I maintain is solely and invariably the case. George Henslow.

YELLOW-FLOWERED MARGUERITES.—I have pleasure in complying with your correspondent, "A. E.'s," request for cultural information on the cultivation of yellow-flowered Marguerites in pots for winter and spring-flowering (see p. 330). In the first place, it may be of interest, and prove useful to "A. E.," to know that the cuttings of these plants are taken in September, and inserted in a cold pit or

about them. Thus treated, they will soon form roots, after which they may be transplanted out-of-doors, affording them as favourable a position as circumstances may permit, and allowing a space of from 15 to 18 inches from plant to plant, according to the size pots which the plants are intended to be flowered in. Make the soil moderately firm about the roots in planting, and affording water to settle the soil about them. As soon as the young plants have taken to the soil and pushed into growth, the points of the shoots should be nipped off, and this should be repeated, when the fresh growth has made a joint, up to the middle of September, or thereabouts, when it must be discontinued. Thus treated, bushy, symmetrical, flat-headed plants will be obtained. When the stopping of the plants is discontinued, they should be ringed round with a spade at the same distance from the main stems according to the sizes of the pot—48's, 32's, or 24's, into which they are to be potted a week or so later—in order to prevent them experiencing any appreciable check in being potted. In doing this, cut close back to the soil all straggling roots before dropping them into properly-crooked pots, working a little fine soil in between the ball of earth and the side of the pot with a piece of lath where necessary and making the soil

ENGELMANN CAÑON.—My attention has been called to the quotation on page 201 of the *Gardeners' Chronicle* for April 2, from an editorial from *Meehan's Monthly*, wherein Mr. Meehan claims that it was so named by himself, and not by the late Dr. C. C. Parry. Up to the publication of my memoir, in 1896, the circumstance of the naming of that cañon was wholly traditional. That is, up to that time no publication of Dr. Parry, Mr. Meehan, or of any one else, contained any reference to the naming of it. Mr. Meehan's editorial referred to is his first published claim to the honour of an act which was performed more than a quarter of a century ago. My authority for the statement that Dr. Parry named the canon was Dr. Parry himself, whose sturdy truthfulness and indisposition to claim credit for himself, even when plainly due to him, were such marked personal characteristics as to have been a subject of constant remark among his friends. Desiring something more than my personal recollection of Dr. Parry's statement to me, I wished to verify it by that of others of his scientific friends. I accordingly addressed several of them (it did not occur to me to address Mr. Meehan), with the result of fully confirming my recollection. For example, Prof. Charles S. Sargent, the well-known author and Director of the Arnold Arboretum,

wrote me as follows:—"When I was engaged upon my work on the Forests of the United States for the Tenth Census, both Dr. Engelmann and Dr. Parry were members of my field party. [See *Gardeners' Chronicle*, July 2, 1881.] While we were encamped near Engelmann Cañon, the fact that it was so named by Dr. Parry, was frequently spoken of by both those gentlemen, and carefully noted by myself." The form of the name as it has appeared in various publications previous to the appearance of my memoir was always erroneous, and was usually "Ingleman's Cañon," a form of spelling that one would hardly suppose was given by Mr. Meehan to the surveyors, to whom he refers. I have hitherto believed that the orthographical error was due to oral corruption by the mountaineers with whom Dr. Parry came in contact during his several years' botanical exploration of that region while it was yet a wilderness. Every surviving friend of Dr. Engelmann will be gratified to know that both Dr. Parry and Mr. Meehan instinctively thought of that great botanist when they first beheld the grandly picturesque cañon at the base of Pike's Peak. No one who knew Dr. Parry, however, will for a moment question the truthfulness of his statement that he gave to it the name of his friend, Dr. Engelmann. *Charles A. White, Washington.*

RAISING CUTTINGS.—The very interesting article on this subject in the *Gardeners' Chronicle*, May 7, recalls to my mind some experiments which I made two years ago. I had the curiosity to see the mode of growth of the spawn of Mushrooms, and so searched the biggest glass emporium in Teignmouth for a glass flower-pot or other vessel suitable for the purpose. Finding nothing that would answer my requirements, I ordered one of the large glass jars which confectioners use for barley-sugar and such-like sweets. On receiving it I at once saw that filled with earth it would be an unwieldy parcel to carry into and out of a dark room; so it occurred to me to fill it with Jadoo fibre. Nothing came of it. Messrs. Hannaford & Son concluded that they had supplied me with spawn too old to grow, and kindly undertook to get me some fresh spawn, which they did. After eighteen months I mentioned to Colonel Thompson with some glee and a certain modicum of "chaff," that I had at length found a plant which would not grow in the much-talked-of Jadoo. In my many conversations with him on the suitableness of Jadoo for sundry and divers purposes, he had never told me that it was destructive to fungoid growths of every kind, or I might have saved myself much expense and trouble, since under these circumstances it is not surprising that I failed to grow any Mushrooms. If therefore cuttings were planted in this fibre, or in any soil which contains a large proportion of finely-sifted Jadoo, the trouble arising from fungoid growths of any kind would be overcome, and most of the precautions dictated by the discoveries by Pasteur and his successors would be rendered unnecessary. *W. Thomson, Bishops Teignton.*

EFFECT OF SCION ON STOCK.—Having a large vineyard, I had a wish to introduce a Vine of Madresfield Court. To do so, I bought a fruiting cane in pot, and inarched it last spring on to a Black Hamburgh, at the same time allowing a few bunches on the pot-Vine, which, on ripening, I found to be Foster's Seedling. It took, and made a good rod on the permanent Vine, but not caring for the variety, I cut it out last winter; but the Hamburgh rod that was inarched on has this spring made shoots like that I have enclosed you, all other Vines in the same house being in good health and vigour. I may add that it was intended for Madresfield and Black Hamburgh to be on the same Vine permanently. Will you please inform me if the inarching has anything to do with the malformation, though it now is growing out of it. They are Vines of some age, and are grown cool. I also inarched the Foster's Seedling on to a Buckland Sweetwater Vine at the same time, which is now showing fruit, and it does not seem to affect the Buckland Sweetwater. All the Vines have had the same treatment for the past seven years, and only the inarched rod is affected. *J. Elliott.* [The scion by contact may alter slightly the characteristics of the produce of the stock on which it is placed, as, *per contra*, the stock may, and often does, alter those of the scion (see *Gardeners' Chronicle*, p. 140, February 9, 1895, and p. 182, September 11, 1897). A case is cited in these pages, *Gardeners' Chronicle*, May 6, 1893, p. 544, in which a white and a red Pelargonium were inarched, with the result that the plant showed red and white flowers in almost equal proportions. One cluster had three white

flowers, two mottled ones, and the rest pure white; sometimes one bloom would have two red petals, and the rest white. This case shows that the scion affects the stock, and *vice versa*; and the same process has occurred in the Vine grafted with Foster's Seedling, although you afterwards cut away the cane produced by the scion. The matter requires and is deserving of fuller investigation than hitherto it has received, but is much more intelligible now that it is known that protoplasm passes from cell to cell instead of each cell being a closed sac. *Ed.*]

ROSE-COLOURED LILY OF THE VALLEY.—We have here a small clump of a rose-coloured variety of Lily of the Valley, of which I enclose some blooms. It is growing against a south wall between fruit trees, and is now in full bloom. I do not observe any difference between the growth of this variety and that of the white one, except that the leaves are a little narrower. *Fredk. Strong, Rochsoles Gardens, Airdrie, N.B.* [An old but seldom seen variety of *Convallaria majalis*. *Ed.*]

DAMAGE BY HAIL.—A thunderstorm of unusual violence passed over Plymouth on May 2. It got so dark at 10 A.M. that one could not read, and heavy hail and rain burst on the town suddenly, choking drains and watercourses, and flooding houses and streets. Cabbages and Lettuces had their outer leaves torn to pieces, exposing the hearts. The foot of the walls was strewn with leaves and small branches of Plum, Pear, &c. I enclose some leaves and fruit of Pear, the fruit pitted by the hailstones. *H. R.*

GARDENERS' CHARITIES AND GARDENERS' WAGES.—"Subscriber" does well in dealing so faithfully with this matter in a recent *Gardeners' Chronicle*. If his contribution does not secure fifty or a hundred more subscribers to the gardeners' charities it will not be for lack of hard-hitting. Whether this latter is the likeliest mode of bringing gardeners into closer or more practical touch with their own charities, remains to be seen. Probably matters will not be greatly improved until gardeners generally grasp the fact that these charities are, and ought to be, chiefly their own affair. Not so much on account of anything they expect to get from them, but because of the opportunity they offer us of helping our comrades and friends, the aged and the afflicted, and the widows and orphans of our brothers of the gentle craft, who have been disabled in the battle of life. I cannot believe that gardeners as a class are selfish or indifferent to the wants and sufferings of their fellows, or their families; quite the contrary. Perhaps no class of men are more brotherly and helpful to each other than gardeners in their daily avocations. Who of us has not found among our friends and neighbours, friends in need at a pinch. Scotchmen in particular, and gardeners in general, can forgive the stinging caricature your correspondent draws of Sandy as "a decent man who keeps the Sabbath and everything else he can lay his hands on," for its broad humour, which they can afford to laugh at with a clear conscience. Neither is it quite fair to attempt to measure the ability of gardeners to support their charities by their manner and appearance at our great shows. "Subscriber" says truly enough, gardeners look well fed, well dressed, well stocked with pocket-money, and brimming over with high spirits. This, in the main, is true. But these big shows are the full-dress parades of the gardeners. Not a few are sent thither by their employers, and others scrape and save for the great shows as the chief holiday of the year. Gardeners' homes are a far better test of their means than their holiday attire and conduct at flower shows. And even here it is easy to be deceived. Sandy and his wife will pinch for the following week, if need be, to place of their best in profuse hospitality before their neighbours and friends, carefully concealing the slightest sign of scarcity or want. No one, however, can go among gardeners very much without finding that the struggle for life and respectability is severe. Victories are won over adverse circumstances in thousands of gardeners' homes that would bring success in most other careers. Largely through lack of means, partly through the impoverishing dependence on nurserymen, employers, and the gardening press, for the support of our charities, these have lacked the whole-hearted support of gardeners as a class. Surely, "Subscriber's" letter may do something to enlist the active sympathy which spells help of a monetary kind, of the thousands of gardeners in these islands whose names appear in the various horticultural directories. One penny each man would prove a donation worthy of the donors and

their objects. A shilling each would probably place every aged and afflicted gardener and their widow and orphaned children beyond the reach of poverty and the yet greatly more dreaded workhouse. Permit me to summon "Sandy," and all other gardeners, to the assistance of his brother gardeners, children and widows—mayhap his own, as in these matters the unexpected is constantly happening. The most cursory glance at our list of orphans, and the pensioners of the Gardeners' Benevolent Institution, prove once more the sad effects of the uncertainty of life. I was prepared to some extent for "Subscriber's" statement about the scant interest in gardeners' charities in Scotland, through a long conversation a few days previously with a gentleman in Edinburgh who has long done what he could for our orphans and disabled comrades. The Scottish Horticultural Association has done yeoman's service for our charities. Still, only 300 practical gardeners contribute to the Gardeners' Orphan Fund, only thirteen of them resident in Scotland, although Scotland has eight pensioners drawing from the funds £104 per annum. Why, that will never do, especially as to secure one vote for every election or support an orphan for a week, a subscription of 5s. a year, or a fraction over 1½d. a week suffices. Could this matter of 1½d. a week for our orphans be put to the ten thousand gardeners in the *Horticultural Directory*, and to the 600 members or so of the Scottish Horticultural Association, can anyone doubt but that it would be carried by an overwhelming majority? Even the most grasping Sandy, if such there be left north o' Tweed, would feel his baubles burning a hole through his breeks if he tried to keep them back from such a fine purpose as the feeding, clothing, and teaching of the orphan bairns of his friends and neighbours, mayhap of his own in the future. Gardeners, too, have often other means of assisting their charities in addition to their life or annual subscriptions. Most employers would be happy to give an open day for the gardening charities, when their gardens are at their best, if the matter were properly placed before them. These, either with or without a band of music, would generally draw a good many sixpences and shillings to the exchequers of our gardening charities. The indirect effect of these local fêtes on open days or half-days, on behalf of our charities, could hardly fail to be felt among all sorts and conditions of gardeners, and to bring in many such as annual subscribers and supporters. *An Original Subscriber.*

ARCTOTIS VIRGATA.—On p. 308 of your recent issue, the last paragraph of the middle column is a statement that good seeds of the above-named Composite have been received at Kew from a correspondent in South Africa, and giving a description which, if accurate, should make it a decided acquisition. There must, however, I think, be a mistake on the part of the sender as to the name, as *A. virgata*, as figured on plate 307 of volume iii. of Jacquin's fine *Hortus Schönbrunnensis*, has comparatively small flowers of a rather dull shade of yellow, and by no means resembling the flowers of the beautiful La France Rose. If the seed sent should turn out to be the lovely *Arctotis rosea*, figured by Jacquin on plate 206 of the second volume of his fine work above-mentioned, as I sincerely hope it may, it will indeed be a valuable acquisition to our gardens. All these fine forms of *Arctotis* are, I believe, indigenous to Namaqualand, a district but seldom visited by Europeans, and though most of them were in cultivation towards the end of last century in the fine gardens of the Emperor of Austria at his palace of Schönbrunn, where Jacquin described and figured them, all are, I believe, long lost to cultivation save three, *A. aureola*, *A. arborescens* or *aspera*, and *A. acaulis*; the last named is comparatively worthless. *W. E. Gumbleton.* [*A. virgata*, like others of the genus, is variable. The sender of the seed is a competent observer. When the plant flowers, the question can be determined. *Ed.*]

DOVER HOUSE, ROEHAMPTON.

THIS exceedingly well-kept suburban-garden offers at all seasons of the year lessons in good cultivation. The greenhouse is now full of specimen-plants of *Souvenir de la Malmaison* Carnations, already in flower, or commencing to bloom. The picture these present may possibly be imagined when we say that some of the plants have forty or forty-five flowering-growths to each. They are two and a half years old, occupy 10-inch pots, and are furnished with most luxuriant foliage to the very base. There

is not the slightest trace of disease, nor is there any disfiguration of the plants from any cause. This type of Carnation is very liable to injury from green-fly; the flies get down in the centre of the growths, and as the leaves unfold, they are seen to be disfigured generally by spotting. There is nothing of the kind, however, in Mr. McLeod's collection, but the foliage is thick, wide, leathery, and of that glaucous hue indicative of the best health. They were scarcely forward enough for exhibition at the Temple Show, so many of the lovely flowers having yet to unfold; but a large group of plants will probably be shown at the Drill Hall during June. The larger plants in the greenhouse do not exhaust the stock, for Carnations are especial favourites of Mr. J. P. Morgan, the liberal proprietor of these gardens, and there are several batches of

Caladiums, in addition to the Crotons, and other evergreen species; whilst the new *Acalypha Sanderi*, figured in *Gardeners' Chronicle*, April 23, p. 248, already adorns the collection with its showy pendent blossoms of rosy-scarlet. The fruit-houses are looking capital, the Vines and Peaches promising well. Peaches were first gathered on April 30, the variety being *Stirling Castle*. During the last few seasons increased attention has been given to Figs, and a small house is now filled with them. We have never seen a better first crop than Mr. McLeod has had this year, and the second crop is also a very full one.

There have been plenty of ripe Strawberries, and there remain 400 plants in pots still to fruit. Mr. McLeod's experience is similar to that of many other gardeners who have found *Royal Sovereign* to be the very best Strawberry for forcing. The results

for the last seven years; Peas, which are just podding, and all other crops, including Asparagus, are growing apace. Since last summer there has been built a capital range of frames, and lately has been felt the convenience that such essential structures to a well-equipped garden always afford. As usual at Dover House, every care has been taken to ensure a fine display during the summer of Carnations and Violas in the outside borders, the annual exhibitions of which are always first class; that of Violas being, so far as the south is concerned, quite unique. A batch of fine plants of *Humea elegans*, just about to flower, will be most handsome ornaments to the flower-garden this season.

LAW NOTES.

Re H. J. SHEPPARD, FLORIST, BEDFORD.

THE public examination of this debtor took place at the last sitting of the Bedford Bankruptcy Court, before the Registrar. The statement of affairs filed by the debtor disclosed gross liabilities amounting to £4814, of which £4420 was expected to rank against the estate for dividend. The business was formerly carried on by his father, and was transferred to witness in 1895. In 1893-94, there were some alterations, in consequence of the Midland Railway Company taking one of the nurseries, and the whole of the stock had to be sold by auction. The stock was worth something like £900, but the nett result of the sale was something like £100. Eventually the examination was adjourned to enable debtor to file further accounts.

Re ALFRED ELLIS, FLORIST, 329, COWBRIDGE ROAD, CANTON, CARDIFF.

This debtor, who formerly carried on business as a florist and nurseryman at the Roath Nurseries, Newport Road, Cardiff, has now filed a statement of affairs showing gross liabilities amounting to £548, of which £515 is expected to rank against the estate for dividend. The assets are returned at £266 5s., thus leaving a deficiency of £249 6s. 7d. The debtor alleges his failure to have been caused through losses on the sale of stock, depreciation in the value of stock, loss of trade in consequence of removal from Newport Road, and bad debts.

FLORISTS' FLOWERS.

CARNATION "HARROW WEALD BEAUTY."

UNDER this name a very pretty, large flowered seedling of *C. Malmaison* is grown by Mr. Dinsmore, gardener to T. F. Blackwell, Esq., The Ceders, Harrow Weald, where it is at present in great beauty. In habit and in the size and form of its flowers the variety closely approaches the old *Souvenir de la Malmaison* Carnation, but its flowers, whose fragrance is like that of the old Clove, are blush-white, heavily flaked with bright rose colour. It seems to be both a good grower and an abundant bloomer for the section to which it belongs.

Obituary.

LORD PLAYFAIR.—The death on Sunday last of this distinguished chemist and politician is announced. Lyon Playfair was for some time Professor of Chemistry in the University of Edinburgh, and was associated with Dr. Lindley in the investigation of the Potato disease on its first appearance. At that time frequent communications of his were printed in the *Gardeners' Chronicle*, but of late years we have not been able to register him among the number of our contributors.

GEORGE EDWARDS.—We regret to inform our readers that Mr. George Edwards, who for upwards of thirty years carried on a nursery and florist's business at Balham, London, and who during the last five years was engaged in the cultivation of flowers, &c., for market, has passed away, at the age of 64.

FIG. 134.—PELARGONIUM, "SPOTTED BEAUTY."

(Shown by Mr. C. Turner, Slough, at the Temple Show. See Report, *ante*, p. 330.

younger plants in other houses now developing their inflorescences. These include the handsomely-coloured varieties, The Churchwarden, Lady Grimston, &c.

The house where the greenhouse flowering-plants are displayed is very bright with a miscellaneous lot of forced plants, very tastefully arranged, with a liberal quantity of ornamental foliage species. The batch of *Codiaeums* (Crotons) is always attractive in this garden, because well grown and highly coloured. The plants are now growing quickly. There are many plants of several promising seedlings raised a couple of years since by Mr. McLeod, of which more will be heard, as they are distinct from others, and possess high ornamental qualities. Opposite, and in the same house as the Crotons, is the collection of *Caladiums*, now looking as pretty as they will look throughout the year. We noticed several of the novelties shown for the first time at the Temple Show last year by Messrs. Veitch & Son, of Chelsea, of which the best are probably *Lady Stafford Northcote* and *Mrs. McLeod*. The plant-stove, which is always full of good specimen plants, now contains fine

from this variety have been excellent, scarcely a plant failing, and the fruits as we saw them are of large size, good colour and flavour.

The hardy fruit trees have produced a great wealth of bloom, but the palm in this respect must be given to the *Morello* Cherry-trees against a wall. Mr. McLeod does not tie these in closely, but the younger growths stretch out from the wall more than a couple of feet, and they have also got a little above the wall. These trees in April were such a show as we have never before seen equalled—not even by Cherry-trees, floriferous though they usually are. If the crop of fruits should have any relation to the blossom, *Morello* Cherries will be abundant at Dover House during the coming season. They have set abundantly, and we hope few of the fruits will fall.

The Sweet Cherries upon the walls have also set a good crop of fruits. Peaches are not more than an average crop; but of Plums there is promise of good crops upon the wall trees and standards. Spring Cabbages (*Ellam's Early*) were in use a month since, and have nice close-hearted heads. Carrots, upon the same ground that has produced this crop

SOCIETIES.

ROYAL HORTICULTURAL.

(MAY 25, 26, 27.)

TEMPLE SHOW PRIZE LIST.

GOLD MEDALS.

Sir T. Lawrence, Bart., for Orchids; Messrs. W. Paul & Son, for Roses; Mr. G. Mount, for Roses; Messrs. James Veitch & Sons, for Caladiums, Crotons, Cacti, Gloxinias, &c.; Leopold de Rothschild, Esq., for pot fruit-trees.

SILVER CUPS.

Messrs. J. Jackman & Son, for Clematis and Herbaceous Plants; Messrs. R. Smith & Co., for Clematis; Messrs. Barr & Son, for Herbaceous Plants; Messrs. Cutbush & Son, for Foliage Plants, Palms, and Carnations; Sir F. Wigan, for Orchids; Messrs. Charlesworth & Co., for Orchids; Messrs. H. Low & Co., for Orchids; Messrs. H. Sander & Co., for Orchids and New Plants; H. S. Leon, Esq., for Orchids; Earl Percy for Orchids; Messrs. Linden, for Orchids; Mr. J. Cypher, for Orchids; Mr. J. R. Box, for Begonias; Messrs. Paul & Son, for Roses, &c.; Mr. C. Turner, for Roses, Pelargoniums, and Carnations; Lord Aldenham, for Vegetables; Sir J. Pease, Bart., for Fruit; Messrs. Rivers & Son, for Pot-fruit; Messrs. Sutton & Sons, for Vegetables; Messrs. Carter & Co., for Vegetables and Flowering-plants; Messrs. Cannell, for Cannas, Gloxinias, Calceolarias, and Begonias.

SILVER-GILT KNIGHTIAN

MEDALS.

Messrs. G. Bunyard & Co., for Apples, &c.; Mrs. Wingfield, for Vegetables; Mr. S. Mortimer, for Cucumbers and Tomatoes.

SILVER-GILT FLORA MEDALS.

Mr. T. S. Ware, for Herbaceous Plants; Messrs. Perkins, for Bouquets, &c.; Mr. H. B. May, for Ferns; Messrs. B. Williams, for Orchids and Decorations; Messrs. Lewis & Co., for Orchids and Decorations; W. Thompson, Esq., for Orchids and Decorations; Jules Hye-Leyson, Esq., for Orchids and Decorations; Leopold de Rothschild, Esq., for Carnations; Messrs. W.

Floral Committee.

From Messrs. J. Veitch & Sons, Chelsea; Caladium Ami Schwartz, Areca lisenanni, from Messrs. Sander & Co.; Erenurus Elwesianus, from Mr. T. S. Ware; to Caladium Guaratuguetor, from Messrs. J. Laing & Sons; to H. T. Ross Aurora, from Messrs. W. Paul & Sons, Waltham Cross; to Tree Paeony Julius Caesar, P. Jean de Reszke, P. Henry Irving, from Messrs. Kelway & Sons, Langport; to Anthurium Scherzerianum Senatore Montefiore Lewis, from Mr. L. De Smet-Duvivier, Ghent, Belgium.

Awards of the Orchid Committee.

First-class Certificates. Cattleya Mendeli Oakes Ames, from Hugh Low & Co., Enfield; Odontoglossum Rodyanum venustum, from Messrs. Linden, Brussels; Odontoglossum crispum x Harryanum, from Chas. Vuylsteke, Loochristi; Lælio-Cattleya Admiral Dewey, and Cattleya Fernand Davis, from Messrs. Charlesworth, Bradford; Dendrobium Dalhousii Salmonia, from Hugh Low & Co., Enfield.

AWARDS OF MERIT.

Cattleya - Lælia Mendeli Amelia, from W. P. Burkinshaw, Esq., Hull; Miltonia Bleuana rosea gigantea, from Jules Hye Leysen, 170, Courpère, Gand; Cattleya Mendeli Mrs. E. V. Low, from Hugh Low, Enfield; Odontoglossum crispum zebrinum, Odontoglossum crispum decorum, Odontoglossum Pescatorei bellatulum, from Messrs. Linden, Brussels; Lælio-Cattleya Intermediiflora, from Messrs. Charlesworth; Odontoglossum Charlesianum, from Mons. A. Madoux, Anderghem; Miltonia vexillaria Empress Victoria Augusta, from Messrs. J. Backhouse & Son, York.

BOTANICAL CERTIFICATE.

To Cirrhopetalum Colletti, from Mr. Ashworth.

CULTURAL COMMENDATION.

Oncidium concolor, from H. S. Leon; Epidendrum prismatocarpum, from W. Cobb, Esq.; Odontoglossum, from W. Thompson, Esq., also special vote of thanks.

Award of the Fruit Committee.

AWARD OF MERIT.

Apple Ontario, from Messrs. Geo. Bunyard & Co.

THE SCOTTISH HORTICULTURAL ASSOCIATION.

MAY 21.—On this date, the members of this Association, to the number of about seventy, visited Gosford House under very favourable circumstances. Two special carriages were put on from the Waverley to Longruddy station, where the party was met by the head gardener to the Earl and Countess of Wemyss, Mr. Cooke, who conveyed them through the demesne and gardens with the utmost courtesy and kindness. Mr. Connor, the head factor and the chief housekeeper to the Earl and Countess of Wemyss, also accompanied the party through the grounds and the best apartments of the Hall, viewing the art treasures of the place, and greatly adding thereby to the pleasure and profit of the visitors. Refreshments were served to the visitors in the dining-room, and after the repast the President, Mr. Todd, returned hearty thanks through Mr. Connor to the Earl of Wemyss for his generosity and kindness to the members of the Association; and Mr. Connor, in responding, bade them all, in his Lordship's name, a hearty welcome, adding truly that Mr. Cooke had a great deal to show his visitors. [We reserve an account of the arboreal and other treasures of Gosford, kindly sent by our correspondent, Mr. D. T. Fish, who accompanied the party, for a future issue, illustrating it with a reproduction of a photograph of the lake. Ed.]

MANCHESTER WHITSUNTIDE FLOWER SHOW.

MAY 27.—The annual Whitsuntide exhibition was opened at the Royal Botanical Gardens, Old Trafford, on the above date. Sir Trevor Lawrence president of the Royal Horticultural Society of London, was among the exhibitors, and he further honoured the Royal Botanical Society of Manchester by paying his first visit to the city and the gardens yesterday.

In accordance with yearly custom, the exhibits were divided between the grand avenue and the Palm-house. The general aspect of the grand avenue was one of brightness and variety of colour. Its brilliancy would have been even greater, but that the comparatively cold and sunless spring had kept back the bloom on a collection of Rhododendrons which Messrs. WATERER, of Bagshot, placed in the lower part of the avenue a couple of months ago. Some of these shrubs were in full flower, but the greater proportion were teeming with unopened buds. Groups of miscellaneous plants arranged for effect formed as usual one of the leading attractions of this part of the premises. In the open class for amateurs, with a space limit of 200 square feet the competitors were Miss LORD and Mrs. G. PEASE (gr., Mr. J. McIntyre). The former lady's exhibit was particularly light in its effects, a result attained by careful selection and distribution of white flowers and bright-foliaged plants, with a background of Cocos, Bamboos, and Phoenix of species. Among the more noticeable of the other component parts of the group were some Dendrobiums of rare culture, Amaryllis, Caladiums, and Alocasias. Mrs. PEASE's competitive display, which obtained for its owner the 1st prize, was of somewhat deeper tone, its ingredients admirably arranged, and its Crotons of special quality; among them was a plant of the fine twisted variety, Prince of Wales.

Miss LORD's gardener, Mr. Wilkes, had another good group in the department for amateurs within twenty miles of Manchester with a space limit of 100 feet. This was rewarded with the 1st prize, and was followed closely in merit by a group from Dobroyd Castle.

Nurserymen's competition in groups was confined to Messrs. R. P. KER & SONS, of Liverpool, and Mr. BRUCE, of Chorlton-cum-Hardy. Each of these collections contained a wealth of floral and horticultural gems. The exhibit of Messrs. KER was rich in Crotons, Begonias (chief among them a new variety, Princess Charles of Denmark), Hydrangeas, bearing huge trusses of white bloom, and other tea-teaceous and rare kinds of leaf and flower. Mr. BRUCE's group, which earned the 2nd prize, depended upon the use of similar materials for its charms. There was, however, a marked difference in his tasteful use of Azalea mollis in various shades of yellow flower. His specimens of pitcher and carnivorous plants were worthy of mention. Mr. JOHN BROWN, of Heaton Mersey, was the only exhibitor of Roses for competition. His contribution was very meritorious, and included a particularly well-flowered plant of Mrs. John Laing.

Among the trade exhibits not for competition, a prominent place was taken by Messrs. SUTTONS' (Reading) exhibit of herbaceous Calceolarias. All the plants were unusually dwarf, profusely flowered, and with healthy foliage, completely covering the pots they were grown in.

Messrs. DICKSON, of Chester, were represented by an interesting show of Japanese Acers, of forms made familiar to us through its use as a subject of decoration on the native fans and screens. Messrs. CLIBBAN & SON, of Altrincham, showed yellow Richardias and other plants in flower, and Messrs. R. SMITH & Co., of Worcester, Clematis.

The Palm-house was devoted to Orchids principally, which were well supported by hothouse plants in many varieties. The general appearance on entering the section was very pleasing. But it must be admitted on a closer view, that notwithstanding the beauty of the whole, there was almost an entire absence of specialties. The plants shown were well flowered, and fairly well cultivated. The prin-

pal species were Lælia, Cattleyas, Odontoglossums, Cypripediums, and Dendrobiums. Interest centred round the competition for the Society's Gold Medal. There were four plants in the running, but the Award clearly lay between two. These were the Lælio-Cattleya eudora var. Madame Albert Hye, of Messrs. VEITCH of Chelsea, and the Cypripedium Olenus (Burford variety) of Sir Trevor LAWRENCE, Bart., of Burford Lodge, Dorking. The two other specimens were an albino Miltonia var., one of the rarest plants in the country, owned by Mr. ELIJAH ASHWORTH, of Wilmslow, and a Cypripedium Cravenianum a smaller flower than that of Sir Trevor's, having a creamy ground-work with crimson spots. This plant is the property of Mr. G. W. LAW-SCHOFIELD, of Rawtenstall. The Cypripedium Olenus exhibited was the only plant in the country of the kind, and it will probably startle the lay mind to learn that it is valued at £1000.

The 1st prize for the best miscellaneous collection of Orchids in bloom, in the open competition, was taken by Mr. JAMES CYPHER, of Cheltenham, who exhibited a splendid group.

In the amateur section, Mr. ELIJAH ASHWORTH, of Wilmslow, took the corresponding honour with an excellently well arranged collection of plants. The same gentleman was also placed 1st for the best collection of ten plants. The group contained two very fine specimens, a Cattleya Skinneri alba, with splendid spikes, and the exceedingly rare Odontoglossum Vuylstekeanum. Mr. THOMAS STATTER, of Stand Hall, was awarded 1st for a meritorious collection of Cattleyas and Lælias. *Extract from Manchester Courier, May 28, 1898.*

EDINBURGH FIELD NATURALISTS AND MICROSCOPICAL.

MAY 28.—Last Saturday the members of this Society went to Lochleven to botanise the shore of the loch. With the exception of a few sedges, Nasturtium palustre and Centunculus minimus, nothing out of the common was found until on the eve of departure, one of the members got a few specimens of the creeping spearwort, Ranunculus reptans, a plant which is said to be found nowhere else in the Kingdom. Very little of the Water-thyme, Elodea canadensis, was observed, although it had been publicly stated a short time ago that its rank growth was spoiling the loch for angling purposes. University rowers on the Cam used to complain of it bitterly for stopping their progress, and they named it Babingtonia pestifera, because their Professor of Botany had got the blame of introducing it into the river in 1847. The plant is an interesting one to this Society, for the male flowers were first discovered in Britain by one of its members, in a pond on the Braid Hills, near Edinburgh, early in August, 1880, and about forty years after its introduction. It usually produces only female flowers, and propagates by division, without developing fresh seedlings, a process which tends to weaken the plant and restrict periodically its freedom of growth. The plant is interesting also to the physiologist, as it shows peculiarly well under the microscope the circulation of the protoplasm.

FORESTRY.

THINNING THE NUMBER OF SHADE-TREES.

THE summer season affords the best time to make notes of the degree of thinning, which the forester may require to put into practice in the felling season, hence the reference to the subject at this date. It is only when we come to regard the character of the usual shade-trees, such as the Beech and Spruce, that the evils of very early or of injudicious thinning are fully apparent. A tree of the common Spruce or a Beech, makes a pleasant picture if well furnished with branches, and would be preferred by most persons to a clean-belled specimen of either; but when such trees are felled, the disposal of the timber often becomes a troublesome matter. In ordinary plantations a certain amount of lateral growth arrests the development of the crown, and the really clean boles fit for sale, which may be termed ideal timber-trees, are oftener the result of accident than design in woods. Most foresters are more fearful of having an occasional attenuated stem than a rough and over-branched one, apparently oblivious that the cubic contents of a tree are determined by its length as well as its girth; that clean timber is worth half as much again as rough, knotty stuff; and that a given quantity of the former can be grown on a smaller area than the same quantity of the latter.

It is a rather curious fact that the timber of shade-bearing trees generally is lower in value than that of the majority of light demanders. Part of this lower appreciation is due to the nature of the woods themselves, quite apart from the method of growing them. Away from the chair-making and manufacturing districts, Beech has little more than firewood value, and large coarse butts hardly pay

for cutting and splitting up. The almost general use of coal as fuel has rendered firewood more and more difficult to dispose of, and for this reason, if no other, the economical working of woods is intimately connected with the amount of clean timber they contain. Except for forming avenues, and as ornamental trees in parks and demesnes, Beech is now rarely planted to any extent, for this reason; but in the chalk districts of southern England there are large areas of Beech-wood which naturally reproduce themselves, and it is beyond doubt that this tree is far and away above any other hard wood in its adaptability to the thinner soils and high-lying situations on the chalk formation. In such districts, therefore, Beech must still be regarded as an important timber-tree, and it is not too much to say that, not only its relative, but in many cases its actual value depends upon its treatment during the first fifty years of its growth. If planted or allowed to grow thickly, and left almost or quite alone for the first twenty years, the foundation of a good crop of timber will be formed, the subsequent development of which may be assured if only the thinning be confined to the removal of none but suppressed and badly-shaped trees. Even the latter, if doing good service by confining better and straighter stems, had best remain until they can be removed without leaving a gap in the leaf canopy, for nothing induces a one-sided and crooked growth so much as the admission of light to the lower parts of the stems. In fact, thinning should be omitted altogether unless it can be done in such a gradual and cautious manner that no stimulus may be given to the growth of side branches until the trees have almost reached their maximum height. At this latter stage moderate thinning is beneficial, and results in a considerable increase in the breadth of the wood-ring, and cases have been recorded where the bark has actually been ruptured by the sudden increase of growth when free thinning has followed a thickly-stocked condition of the wood. When Beech is grown in this way it will be found quite as profitable a crop as the majority of coniferous trees, which have little or no market value. Of course, few landowners plant woods entirely of Beech with an idea of profits being made; but where Beech woods are in existence their perpetual reproduction is simply a matter of management, and is not attended with the expense inevitable in reproducing most other species of timber trees. If Beech were regularly mixed with Larch on thin, chalky soils, the growth of the former would not only be benefited, but a crop of clean Beech would still remain on the ground after the Larch had matured and been removed. The shade of the Beech foliage is undoubtedly beneficial in keeping a soil moist and cool, and further assists in this work by the rich and heavy layer of dead leaves which each autumn lays upon the surface; and a cool, moist soil is probably one of the most important factors in the growth of healthy Larch in the south of England. *A. C. Forbes.*

VARIORUM.

AT MACKAY: A QUEENSLAND FOREST.—"My first walk in the wild tropical jungle next morning I cannot forget. I entered, sketch-book in hand, by a narrow little pathway, probably made by an alligator. I kicked, as I thought, a grey stick aside—it was a snake, and, quick as lightning, it darted off, while I grew hot and cold by turns. There was such a death-like silence about me that I felt an intruder there, and the thick and tangled mass of rank vegetation completely hid the sun from sight. A few steps farther on I came to an opening, and below me lay a miniature lake, its water covered with dark blue Lilies floating amid their leaves, on which the sun shone through a network of graceful Palms. Scarlet, yellow-eyed dragon-flies skimmed over its surface, while presently a great butterfly tremulously fluttered past, and the sunlight, catching the metallic lustre of its wings, changed them to every rainbow hue. The trees were clasped and linked together by delicate tendrils, and climbing Ferns and huge Caladiums covered the ground. It was a scene of wild, mysterious beauty, but in the distance there was the hum of a thousand gossamer-winged and hungry insects, and I hurried on with my sketch, for the mosquitoes had already found me out. Too much wrapped up in my work to turn round, I pushed twice aside from my cheek what I took to be a hanging tendril; but

surely it moved too quickly—one wild jump, and I was yards away! It was a long tree-snake that had fastened its tail to a branch, and, curious to find out what manner of being this might be that had disturbed its solitude, was gracefully swaying backwards and forwards. This was the climax, and with a good deal of slipping and scrambling, I left the scene without a regret." *A Flower Hunter in Queensland and New Zealand, by Mrs. Rowan.*

THE WEATHER.

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named; and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

The districts indicated by number in the first column are the following:—

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

THE PAST WEEK.

The following summary record of the weather throughout the British Islands for the week ending May 28, is furnished from the Meteorological Office:—

"The weather during this period was fairer and drier than in the weeks immediately preceding it, but a good deal of cloud prevailed in some districts, and showers were experienced in most places either at the beginning or towards the end of the week. Thunder and lightning occurred in some parts of England, mostly on the 22nd.

"The temperature was below the mean in 'Scotland, N. and E.,' 'England, N.E. and E.,' and the 'Midland Counties,' but rather above it in 'Scotland, W.,' and 'England, S., S.W., and N.W.,' and just equal to the normal in Ireland. The highest of the maxima were recorded on Monday over England, on Saturday in Scotland, and on irregular dates in Ireland; they ranged from 77° in 'England, E.,' and 76° in 'England, S.,' to 65° in 'Scotland, E.' and to 61° in 'Scotland, N.' The lowest of the minima, which were registered during the latter half of the week, ranged from 33° in 'Scotland, N.,' and 34° in 'England, E.' the 'Midland Counties,' and 'Scotland, W.,' to 39° in 'England, N.W.,' and to 50° in the 'Channel Islands.'

"The rainfall was less than the mean in all districts, excepting 'England, N.W.,' the fall over the eastern districts of Great Britain and in 'Scotland, W.' being very slight. Heavy local rain fell in some places; at Liverpool on Sunday, and at Culmpton on Tuesday, more than an inch was measured, the amount at the latter station falling in forty minutes, during a thunderstorm.

"The bright sunshine was deficient in nearly all districts, but equalled the normal amount in 'England, E.,' and exceeded it in 'Scotland, W.,' and 'England, N.W.' The percentage of the possible duration ranged from 49 and 59 in these two latter districts, and 48 in the 'Channel Islands,' to 32 in 'England, N.E.,' 27 in 'Scotland, N. and E.,' and 26 in the 'Midland Counties.'"

MARKETS.

COVENT GARDEN, JUNE 2.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand; and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

Horseradish, foreign per bundle	0 9-1 0		
Leeks, new, dozen bunches	2 0—		

REMARKS.—Apples and Cucumbers slightly advanced in price, the Cherries in pecks quoted above were very good bold fruit, of the Turkey-heart kind. Broccoli is now nearly gone, but please note Cauliflowers have commenced. English Peas above quoted were I believe from the West (Somerset); home-grown from Kent and other early spots are daily expected. Cabbage have been a low price all the season, and unless they have been of good colour they had better have been ploughed in, as there is no chance now of their becoming a leading vegetable. Among Apples the New York Pippin fetched top price.

FRUIT.—AVERAGE WHOLESALE PRICES.

s. d. s. d.	s. d. s. d.

POTATOS.

Supply of New Potatoes gradually increasing, with a corresponding drop in prices. Jersey New Potatoes, 12s. to 13s.; Cherbourg and St. Malo, 11s. to 12s.; Lisbon and Malta Rounds, 8s. to 10s.; Canary Kidneys, 12s. to 14s. per cwt.; Old Potatoes, Dunbar Maincrops, 150s. to 160s.; other Ware, 120s. to 145s. per ton. Foreign Ware, 4s. 6d. to 6s. 3d. per bag. John Bath, 32 and 34, Wellington Street, Covent Garden.

SEEDS.

LONDON: June 1. — Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., report to-day's seed market very thinly attended, with but little business passing. Clover seeds just now claim but little attention. For sowing Mustard and Rape seed there is a fair inquiry. Bird-seeds sell slowly. Tares still find occasional buyers. The new Florida Velvet Beans, of which there is a small quantity on the market, attract attention at 2s. per lb. There is rather more inquiry for Peas, Haricots, and Lentils, at unchanged rates. Other articles offer no subject for comment.

FRUIT AND VEGETABLES.

GLASGOW: June 1. — The following are the averages of the prices at this market during the past week: Apples, Canadian Spy, 24s. to 26s. per barrel; ditto, Russets, 24s. ditto; ditto, Western States (Winesops), 20s. to 22s. do.; ditto, Russets, 18s. ditto; Grapes, home, 3s. 6d. to 4s. per lb.; ditto, foreign, 6d. to 1s. ditto. Vegetables: Cabbage, spring, 7d. to 10d. per dozen; Cauliflowers, Dublin, 2s. 6d. do.; Herbs, assorted, 1d. to 2d. per bunch; Mint, green, 6d. to 9d. per 1 lb. bunch; Onions, Dutch, 8s. per cwt.; do., Portugal, 14s. to 15s. per case; Parsley, 1s. to 1s. 6d. per stone; Potatoes, best, 1s. per stone; Carrots, 8s. per cwt.; Artichokes, 1s. 3d. per stone; Peas, 4d. to 5d. per lb.; Cucumbers, 4d. to 6d. each; Strawberries, round, 6d. to 1s. per dozen; do., Cos, 4s. do.; Radishes, 9d. to 1s. 6d. per dozen bunches; Horseradish, 1s. 6d. to 3s. per bundle; do., French, 9d. per stone; Mushrooms, 1s. to 1s. 2d. per lb.; Beetroot, 6d. to 7d. per dozen; Spinach, 1s. 6d. to 2s. per stone; Rhubarb, 2s. 6d. per cwt.; Turnips, Swedes, 4s. per bag; do., white, 10d. per large bunch; Broccoli, 2s. 6d. to 3s. per dozen; Greens, 3s. per ten dozen; Asparagus, 1s. 3d. per bundle.

LIVERPOOL: June 1. — Average of the prices at undernoted markets: — St. John's: Potatoes, 1s. 2d. to 1s. 4d. per peck; do., new, 1½d. to 4d. per lb.; Peas, 6d. do.; Asparagus, 2s. 6d. to 3s. per 100; Cucumbers, 4d. to 6d. each; Strawberries, 8d. to 1s. per lb.; Gooseberries, 4d. do.; Cherries, 6d. do.; Apricots, 1s. 6d. per dozen; Grapes, home, 2s. 6d. to 3s. per lb.; do., foreign, 8d. to 1s. do.; Pines, home, 4s. to 6s. each; Mushrooms, 1s. 3d. per lb. Birkenhead: Potatoes, 1s. 4d. per peck; do., new, 1½d. to 2d. per lb.; Peas, 5d. do.; Asparagus, 2s. 6d. to 4s. per 100; Cucumbers, 2d. to 6d. each; Apricots, 1s. 6d. per dozen; Gooseberries, 4d. per lb.; Cherries, 8d. do.; Strawberries, 6d. to 1s. 6d. do.; Grapes, home, 2s. 6d. to 4s. 6d. per lb.; Pines, home, 6s. to 10s. each; do., foreign, 4s. to 6s. each; Mushrooms, 1s. to 1s. 6d. per lb. North Hay: Potatoes, per cwt., Jersey, 12s. 6d. to 13s.; Giants, 4s. 3d. to 4s. 9d. do.; Main Crop, 5s. 4d. to 6s.; Bruces, 5s. to 5s. 6d. do.; Onions, foreign, 6s. to 6s. 6d. do.; Parsley, 4d. to 6d. per dozen bunches; Lettuce, 6d. to 8d. per dozen; Cucumbers, 2s. to 3s. per dozen; Cauliflowers, 1s. 6d. to 3s. do.; Cabbages, 4d. to 7d. do.

CORN.

AVERAGE PRICES OF BRITISH CORN (per imperial qr.), for the week ending May 28, and for the corresponding period of 1897, together with the difference in the quotations. These figures are based on the Official Weekly Return: —

GARDENING APPOINTMENTS.

MR. W. HASKINGS, for the past two years Gardener at The Limes, Lower Edmonton, as Gardener to J. A. KNIGHT, Esq., Holme Chase, Bletchley, Buckinghamshire.

Mr. C. A. BAYFORD, gardener for the past two-and-a-half years at Glewstone Court, Ross, as gardener to the EARL OF LICHFIELD, Shugborough Hall, Stafford.

Mr. GEORGE BAKER, late Foreman at Lambton Castle Gardens, Fence Houses, under Mr. HUNTER, as Gardener to W. T. DOXFORD, Esq., M.P., Grindon Hall, Sunderland.

NOTICES TO CORRESPONDENTS.

BOOKS: T. C. M., Belfast. You would find MM. Vilmorin & Andrieux's *The Vegetable Garden*, published by John Murray, Albemarle Street, Piccadilly, a much superior work to the one you mention, although it treats in matters of culture of French methods. Abundantly illustrated. Price about 15s. A book of moderate price is *The Culture of Vegetables, and Flowers from Seeds and Roots*, by Sutton & Sons, Reading, seventh edition; it is descriptive of English methods chiefly. — *Nurseryman. The Nursery Book*, by L. H. Bailey, and published by the Rural Publishing Co., New York; *The Fruit Manual*, by R. Hogg, published at offices of *Journal of Horticulture*, No. 12, Mitre Court Chambers, E.C.; *The Dictionary of Gardening*, by G. Nicholson, and others, published by Upcott Gill, 170, Strand, W.C.; *Orchid Growers' Manual*, by B. S. Williams, and sold at the Victoria and Paradise Nurseries, Upper Holloway, N. *The Book of the Rose*, by W. Paul, Waltham Cross, Herts, and sold by him; *Book-keeping*, by Pitman; *A Manual of the Coniferae*, by J. Veitch & Sons, obtainable at the Royal Exotic Nursery, King's Road, Chelsea, London, S.W. These are only a very few indispensable books out of a great number which every horticulturist, commercial, or other, ought to possess. All the gardening papers contain text as well as advertisements.

GOOSEBERRY WITH FUNGUS ON THE LEAVES: J. B. The fungus *Aecidium grossulariae*, figured and described in our issue for June 20, 1891. The usual remedies against fungus may be used, viz., sulphur, the Bordeaux Mixture, sulphide of potassium—this last at the rate of ½ oz. in one gallon of water.

GRAFTING: B. M. D. The inner layers of stock and scion should be brought into contact; and in the case of budding, the two layers that meet should be identical.

GRAPES: T. Evans. — The Grapes are attacked by the Vine Mildew (*Oidium Tuckeri*), described and figured in this paper by Rev. Mr. Berkeley in 1847, p. 779, and frequently referred to since. Use some of the sulphur remedies given in these pages last August.

MUSHROOMS: Jules Gachelin. We may suppose that the Mushrooms would grow larger than two inches across if you would let them remain on the bed. Perhaps, as you suggest, they grow too thickly in parts, and a thinning-out of the "buttons" would certainly tend to increase in size in those that are left.

NAMES OF PLANTS: Correspondents not answered in this issue are requested to be so good as to consult the following number. — C. B., Chester. *Jasminum simplicifolium*, more commonly known in gardens as *J. gracile*. — W. T. Choisy. *ternata*. Hardy in most places. — Bucks. The flowering shrub outdoors, *Prunus Padus*. The Fern, *Adiantum Waltoni diffusum*. The box was completely smashed, and others may have fallen out. — H. D. The *Coreopsis* seems to be a slight improvement on the ordinary good type of *C. grandiflora*. — H. G., R. K., S. R. *Prunus Padus*. — B. H. J. Probably, *Geum coccineum*.

PEACH LEAVES HOLED: J. D. & H. G. See answer to W. T. (p. 336) of our last issue.

PEACH-TREES IN ILL-HEALTH: G. T. If you are sure that the rotten wood is breeding fungus detrimental to the living roots of the Peach-trees, and this is very likely to be the case, nothing you can do short of lifting the tree in early autumn will be of any avail. At that operation every bit of wood found in the soil should be gathered up and burnt, and a considerable proportion of fresh loamy soil incorporated therewith.

RED SPIDER ON VINES: M. T. If the acarus has become numerous on the foliage, and there are Grapes on the Vines, you might remove the former with soapsuds and a piece of sponge, or you may vaporise the Vines with the XL All liquid. Syringing the leaves from below tends to keep red spider in check, but it is seldom sufficient in itself to keep all of the foliage clean, and unless it be carefully

performed the Grapes suffer from it in appearance. The use of sulphur in the evaporating troughs, and smeared, in union with whitewash on the hot-water pipes and walls, tends to make the air in theinery distasteful to red spider, but it will not drive them out if once they effect a lodgment on the Vines. The best means to employ, therefore, are vaporising, sponging, and moderate applications of clean rain-water, with an elbowed nozzle on the syringe.

RIPENING OFF BULBS OF LILIES: J. G. When the flowering is past stand the bulbs, if in pots, in a warm sheltered place out of doors, affording water as usual till the first signs of yellowing in the leaves is observed; then afford it in gradually increased intervals of time, and when general decay sets in withhold water entirely; cut the stems down to within six inches of the soil, and turn the pots on their sides, and treat in exactly the same manner as Cape and fancy Pelargoniums or Callas. The bulbs should remain in the soil till a beginning is made with repotting in September. In the case of *L. longiflorum* and its variety *Harrisii*, the bulbs may, in order to lengthen the season of flowering, be repotted at intervals from that date till the end of the winter; and till even a much later season if you have the convenience of a cool chamber, such as that in which dead meat from America is imported, only the bulbs must not be frozen. You can only obtain one crop of flowers from the bulbs in twelve months. The flowers cannot be hastened by forcing the bulbs, but the temperature of an intermediate house—say 50°-55° by day and 45° by night, may be afforded these and other Lilies after the flower buds have formed. Mice and rats are apt to eat the bulbs in winter if other food be scarce, and if there are signs of this, tiles or slates should be placed over the repotted and the undisturbed bulbs. Mice and rats are particularly partial to those of *L. auratum*, but they are usually impartial in their tastes. In the case of very early flowered bulbs, the ripening-off must be carried out under glass, but the potsful of bulbs should be turned on their sides against a sunny wall like the others in April.

SEEDLING CARNATIONS: H. E. No. 1 is a very large flower, and of a pretty tint of salmon-pink, but it is a calyx-splitter, and would be unpopular from this cause. It has very little or no scent either. The other two varieties are pretty, and should be valuable for cultivation in the border.

SITUATION IN BOTANIC GARDEN: E. A. C. In each case you should address the Director, affording copies of certificates and other information in regard to age, gardening experience, &c.

SQUIRRELS' (HARES') FOOT FERN: H. J. G. This name is usually applied to *Davallia canariensis*.

VINES: Runnymede. Your Vines are attacked by the Downy Mildew (*Peronospora viticola*). Remove diseased leaves as far as safe and destroy them. Though it is rather late to save the crop, a dilute Bordeaux Mixture, prepared as described in this paper last August, might be sprayed on the Vines every two or three weeks till the Grapes are three-fourths grown. After the fruit is off use the Bordeaux Mixture freely. Next season another spraying should be given just after the first leaves have fully expanded, and again after the flowers have set. If the mildew appears again, resume the spraying at once. A little more air and a slightly drier house might also help you this year. The *Gloxinias* on arrival here bore the same fungus; try a similar treatment with them. If the mixture used should stain the foliage, use it more dilute. W. G. Smith, Leeds.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper, MORE THAN DOUBLED, and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, and ALL CLASSES of GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN and COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

THE

Gardeners' Chronicle.

SATURDAY, JUNE 11, 1898.

THE CHRONICLE OF A LITTLE CORNISH GARDEN.

MAY.—The most significant flowers in my garden are the Laburnums "rich in streaming gold," and the pointed blossoms of the Lilacs "rising delicate, with the perfume strong I love." I am afraid that most people are still unfamiliar with Whitman's great poem "When Lilacs last in the door-yard bloom'd"; but to those who have read it, and reading, understood, the appearance of the sweet Lilac flowers must ever recall its rhythm and profound motive:—

"Lilac and star and bird twined with the chant of my soul,
There in the fragrant Pines and the Cedars dusk and dim."

Nowhere else is the advent of death welcomed by so virile a voice:—

"Prais'd be the fathomless universe,
For life and joy, and for objects and knowledge curious,
And for love, sweet love—but praise! praise! praise!
For the sure-enwinding arms of cool enfolded death."

Dark mother always gliding near with soft feet,
Have none chanted for thee a chant of fullest welcome?

Then I chant it for thee, I glorify thee above all,
I bring thee a song that when thou must indeed come, come unflatteringly.

* * * * *
The night in silence under many a star,
The ocean shore and the husky whispering wave whose voice I know,
And the soul turning to thee, O vast and well-veiled death,
And the body gratefully nestling close to thee."

The interests afforded by association are half the value of a garden. In her very interesting *Pot Pourri from a Surrey Garden*, Mrs. Earle quotes an Irish peasant, whose cabin had just been transformed into "the graceful neatness of an English cottage," as saying "it is all very kind, but the good lady does not know how dear to a poor man is everything that reminds him of the time when he played instead of working." Taken in its widest sense this is most true. Every Laburnum-tree in bloom takes me back at once to my old home, where a Laburnum over-arched an entrance, and the memory of it is full of associations of my life as a boy. I find, indeed, that I have unconsciously planted in my garden almost every flower which was grown at my old home.

The weather has been remarkable. Cold cutting winds have spoilt many of the flowers

of April and May, to which I had looked forward with pleasant anticipation. For about a week my late Tulips were glorious, but then one morning I came down to see them bruised and stained and broken. Still, things might have been worse, and I was able to see the picture at its best, even though for a short time only. Gesner's Tulip came fully up to my expectation, the brilliant red flowers showing up well against the foliage of tufted Pansies with which they were carpeted. The other self-coloured Tulips were most successful, some yellow Darwin Tulips being particularly effective. Another Tulip which has done well with me is the rosy-white T. Clusiana, the colour of which is very beautiful and delicate. As I have said, the wind and pelting rain quite spoilt all the Tulips, but I fancy they are flowers which one would not wish to see constantly for many weeks.

The Anemones were scarcely damaged owing to the more flexible character of their stems. The season, like every season, is not at all what it should be according to our preconceived notions. The common idea of the character of the months is all superstition and error. The really great poets and prose writers, who have given us our most valuable and permanent descriptions of country life and affairs, have generally been cockney-trippers like Walton; or, at any rate, natives of London, like Chaucer, Spenser, Milton, and Herrick. The countryman, born and bred, is usually unable to feel the poetry of his surroundings—he cannot see the wood for the trees—and hence he is usually unable to produce great literature dealing with the facts of which he knows most. Therefore, it is that our ideas of "spring," "the month of May," and the rest are not in accordance with the facts.

Looked at from a little distance, the greatest show in my garden at present is given by the yellow Wallflowers, of which I have a number of great bushes. Yellow is a very effective colour when seen even from a considerable distance. Mrs. Earle's advice is good where she says that the smaller the garden the more essential it is to get a succession of colour.

The mass of double Narcissi of which I spoke last month is now beautiful, and pleads strongly for the artistic recognition of double flowers. Nevertheless, charming as are these flowers in a mass of seventy or eighty blooms, with their delicious scent wafted hither and thither by the breezes, I still hold the opinion that as individual flowers they cannot for a moment bear comparison with the single Poet's Narcissus.

A very common flower which is now in bloom does not receive the homage which is its due. I refer to the little evergreen *Saxifraga umbrosa*, London Pride, None-so-pretty, or Queen Anne's Needlework, as it was once called. I have only one great spreading clump, developed from a single plant in the course of the last two or three years; but this clump is at present one of the most interesting and beautiful objects in the border. From the pretty green rosettes spring numerous tall quaint hairy flower-stalks, branching in Japanesque fashion, bearing panicles of the most exquisite little jewels of flowers. Each of the five small white petals is dotted about its centre with red, and towards the centre of the flower with yellow; whilst the erect white stamens are terminated by anthers coloured terra-cotta. The frequency of the plant's occurrence, and the fact that the flowers require close inspection to be properly appreciated, probably accounts for London

Pride being commonly considered a sort of weed. Near the clump of London Pride is a "blue cataract" of *Veronica prostrata*, hanging over some stones. This is the first to bloom of several *Veronicas* which I recently planted, and it already appears well established.

The golden and sulphur *Eschscholtzias* are beginning to produce a distinct effect. The flowers are larger than last year, and again than the year before. They are with me, and in the situation I have chosen, strictly perennial, although usually described as annual. Each autumn, after they have finished flowering, I simply cut them down with shears, and they are now quite large bushes, of the freest and most luxuriant growth. The *Eschscholtzias*, like many other cup-shaped flowers—*Anemones*, *Poppies*, *Rock-Roses*, &c.—produce no honey, but are visited by insects for pollen only; hence their simple shape, having no nectaries to protect from marauders by various quaint devices and modifications of form.

Many of the tufted and other Pansies are sheets of beautiful flowers. Of the *Violas* I have, I like best the lavender *Duchess of Sutherland*, the sweet-scented, cream-coloured *Sylvia*, and the appropriately named *White Duchess*; but when all are very beautiful, it seems invidious to select a few.

Pæonies I have not yet planted to any extent, but propose getting a few more next autumn. The single European varieties have been in flower for some little time, and have all done well, the best I have being a satiny-white one known as *Emodi*, which I believe—to be strictly Irish—is really a Himalayan species.

Many weeks ago I had flowers of the pink *Rosa alpina*, and blooms on my *Gloire Dijon*, and there are now several *Roses* fully open, including the beautiful buff *Safrano* a very vigorous Tea, the unique Austrian Copper Briar, with dull-red golden petals, resembling no other flower, and also several of the summer *Roses*; but, of course, the *Roses* will not be at their best till later.

The *Silene pendula* which carpets the Rose-border is an expanse of pink, but the rich soil has made it grow rather too luxuriantly for a carpeting plant, and next autumn I propose to use *Primroses* for the border instead. These will commence to flower much earlier, and will be of lower growth. A couple of plants of *Geum chilense* which I sowed under the name of *G. coccineum* are just beginning to flower. They are most satisfactory plants, about 18 in. high, bearing panicles of brilliant scarlet flowers.

The dwarf *Phloxes* are sheets of pink and white flowers, the leaves being quite hidden by the masses of bloom. These, again, have quickly established themselves, and I shall get any other species or varieties I can. That is, without doubt, the wisest course to follow in amateur gardening. Try by experiment what plants really flourish under your conditions of soil, climate, and the rest, and then grow the best of the allies and varieties of those plants. Still, there is an irresistible impulse in every gardener's breast to try to grow any flowers he has hitherto failed with; but, if he be wise, he will conduct his essaying on a reasonably small scale rather than waste money in large consignments of plants doomed to serve as manure for his borders.

Oxalis floribunda is a mass of rose in the sunshine, but for some twenty-three hours a day the flowers are closed; still, as it blooms all through the summer, I suppose it will sleep a little less when we have more sunshine.

It is surprising how few people with large gardens make any considerable use of their opportunities. In looking round the capacious grounds of acquaintances, I am constantly struck by the small number of flowers grown in proportion to the situations offered. My little plot then seems to be quite cultivated. At the same time, there is no getting over the fact that no amount of good gardening will compensate for the advantages which space, trees, grass, and situation give.

The curious and beautiful varieties of *Mimulus* are now flowering in every shade of red, brown, and yellow. The *Mimulus* is much like an Orchid in its elaborate arrangements for placing its pollen on insect visitors, and so promoting cross-fertilisation. The hairy petals, especially the lower one, keep out unwelcome insect-robbers.

The Forget-me-Nots help to brighten the garden, and assist the general spring aspect. The early Forget-me-Not (*Myosotis dissitiflora*), and the wood species (*M. sylvatica*), are the two which I have raised, and both are very bright and free-growing. I mean next season to try *M. lithospermifolia*, said to bear the largest flowers of any Forget-me-Not, and the dwarf alpine species (*M. alpestris*). The interesting habit of Forget-me-Nots of moving aside the old flower-stems, and even the individual flowers when fertilised, helps to keep the plant continuously bright with flowers in their prime. The plant's object in so doing is, of course, to present new flowers to insect visitors, and not to please useless human eyes.

The Pinks are beginning to open, and are developing their delicious scent. I am especially looking forward to the single ones. Some autumn-sown Sweet Peas are making good progress; many Irises are beginning to show colour, and a number of summer flowers are sending up flower-stems ready to unfold in a few weeks. The *Deutzias* and *Mays* have not yet expanded their blossoms, but a few days will probably make a difference.

The leaves of the dwarf fruit-trees now help very materially to furnish the garden, and to afford a background for the tall herbaceous plants of the borders. Such a mixed system of gardening appeals to me as the ideal for ordinary mortals. It is of a kind with the idea of art applied to the utilities of every day, rather than with the art which we may call *dilettante*. It resembles rather a tastefully-furnished living-room than an ornate and vulgar drawing-room, bearing no relation to ordinary life. *Harry Roberts.*

NEW OR NOTEWORTHY PLANTS.

DORSTENIA ARABICA, *Hems.*

This is one of the most curious species of a remarkable genus, and was introduced to the Cambridge Botanic Gardens by the kindness of Mrs. Lort-Phillips. It forms a stout fleshy stem of several inches in height, bearing a few leaves only, of oval outline, dark green in colour, with a tendency to a greyish tint, and with sometimes a shade of purple. The receptacles are curious on account of the barren spoke-like extensions, almost evenly rayed from the centre. *Dorstenia arabica* was not a published name up to the year 1885, but a scrap in the Kew Herbarium is so designated by Mr. Hemsley, and certainly the plant here figured is identical with that. It was sent from Somali-land. The accompanying illustration [not reproduced] was kindly drawn for me by my friend Mr. F. W. Burbidge, M.A., V.M.H.

HUERNIA SOMALICA, *N. E. Br.*

The plant here represented is so like a *Stapelia*, both in its vegetative and floral parts, that for garden purposes few would be disposed to quarrel with its position if placed in that genus. *Huernia* differs, however, in having a broadly campanulate corolla, while that of *Stapelia* is either rotate or reflexed. The corolla, too, of the former has a toothed sinus, while that of the latter is naked, and these differences, together with further unlikeness in the corona, require a distinction to be made. The plant is decidedly attractive among its congeners, having a large brown flower with polished surface, and stout greyish-green stems. It was introduced to the Cambridge Botanic Gardens by Mrs. Lort-Phillips. The above name was kindly given at Kew. *R. Irwin Lynch.*

SENECIO HANBURIANUS, *nov. sp.**

The subjoined description of a new species of *Senecio* has been sent us by Mr. Dinter, who must be a bold man to add to the many hundreds of species of this genus.

THE GERMINATION OF SEEDS.

In the article signed "W. W.," in your issue of March 26, 1898, reference is made to loss of Rubber-seeds in transport, to keeping seeds in canvas-bags, and to the keeping of seeds in hermetically-sealed tins; but no information is given as to why seeds keep best in canvas-bags, what caused the loss of the Rubber-seeds, and why it is "fatal" to put seeds into hermetically-sealed tins. Further, the writer says that old, weak seeds of doubtful vitality are more likely to germinate under the stimulating influence of a high temperature than if given an ordinary temperature.

Now I have not the slightest doubt that in these statements the writer records the results of his own experience, and would probably be quite ready to admit that his article did not deal fully with all points of the question, for, *per contra*, I am able to state that Rubber-seeds have been sent from the tropics to England for distribution, without loss, on numerous occasions; that seeds in canvas-bags will not keep, and that hermetically-sealed tins are an excellent means for the preservation of seeds. Your correspondent therefore should not be satisfied until he has discovered the reason for the loss he records, the reason why his seeds keep best in canvas-bags, and the reason why hermetically-sealed packages are sometimes fatal; for when it can be truly asserted that the contrary is frequently the case, this proof is certainly incumbent on him.

It is a well-known fact that circumstances sometimes alter cases, and in my own particular field (a tropical garden) the experience I can record differs essentially from that put in print by your correspondent.

On several occasions I remember sending home, by request, consignments of Nutmeg-seeds early in the year. The report on these seeds showed that they had suffered in transport, and all had become rotten. Now the seeds were packed in the same way and in the same condition as others sent several months later, or during warmer weather, which latter consignment arrived safely, and grew well. The inference therefore is fairly clear that the seeds sent in cold weather were, in fact, chilled; and subsequent trials have proved the case more clearly, for it is found that if tender seeds are sent from the tropics to arrive in cold weather, there is great danger

* *Senecio Hanburianus*; suffruticosus; caulibus carnosis glabris ramosis, 5 poll. longis; foliis 8—13 poll. longis, chordiformibus leviter sulcatis mucronulatis glaucis; cymis elongatis laxis 4—8-cephallis; pedicellis elongatis squamulosis 1-cephalis, capitulis subcylindricis basi 8—10 patente bracteolatis discoideis homogamis circ. 45 floris, involucri striatis circ. 13—15 phyllis disco vix brevioribus, foliolis lineatis obtusiusculis, 3 nerviis marginibus late membranaceis; floribus pallide ochroleucis, corollae lobis lanceolatis recurvatis; staminibus exsertis, stylis ramis apice truncatis; achenio albo pubescente.

Species affinis *Senecione chordifolio* Hook., attamen distinctissima. Patria ignota, verisimiliter ex Africa capensi introducta, culta in horto Mortolensi. *Dinter.*

of their being spoiled; while if they are during the summer months, much more success attained.

To hang our seeds in a bag in a dry place in a medium uniform temperature is with us an utter impossibility. In the first place, we have no dry place, our air contains on the average for the year over 77 per cent. of moisture, and often at some seasons for long periods of the day stands at saturation point. In the next place, our temperature reads 87° (mean max.), and 70° 7' (mean min.), and a bag of seeds hung up in the most desirable place to be found would soon be perfectly useless, for in a few days the seeds will have lost their germinative power from the alternations of humidity and heat. A high temperature carries a larger amount of humidity than cool air, and I would ask "W. W." if he does not think it probable that this humidity is as great a factor in seed-life, as he must I think know it to be in plant life, and that germination depends more upon being subjected to its influence than to any particular range of temperature, and that temperature only materially affects seeds when aided by moisture. In the case of the Nutmegs referred to, the chill was undoubtedly caused by their being packed moist; but if they had been dry the result would have been the same, as it is well known here that once a Nutmeg becomes dry, or as dry as it will get, it has lost its germinating power, and the only possible way to preserve them is to keep them moist until germination occurs. If, however, the temperature is considerably lowered, decay at once sets in, for it acts as a check upon growth, and a check in this stage means destruction. In the tropics it is almost impossible—at any rate, during the rainy season—to keep seeds so as to maintain their germinating power; and this is often destroyed by other means than by temperature and moisture, for we have to contend with numerous insect enemies, such as ants, weevils, &c., which, as one would think, maliciously eat out the embryo.

During rainy weather there is sufficient humidity in the atmosphere itself to induce slow germination, which may, or may not be perceptible, and when this has once taken place, the dryness or alternation of humidity and dryness will kill the seeds, if they are not in a situation to maintain growth. Again, the hermetically-sealed tin may be at times, and under certain conditions, deadly for seeds, but there can at the same time be no possible question as to its usefulness for preservation purposes. Its success depends, of course, entirely upon the state of the atmosphere at the time the sealing is effected, and on the condition of the seeds when sealed. If tins are sealed when the air is saturated with moisture, rotten seeds may be expected when the tins are opened in the tropics; but if the seeds are sealed on a dry day, or in rooms where the air is quite dry, they will certainly keep good for a greater length of time than if put up in any other way. If growers could only persuade seedsmen to take a lesson from the biscuit-makers, it would be a great advance made. Ginger-nuts or other biscuits keep perfectly well in the patent tins easily opened with a thumb-piece, and so would seeds, if put up in a proper way in similar packages, and the package would cost little more than the ordinary envelope, and would certainly be accepted as a boon by growers in the tropics.

What "W. W." says of old seeds may be true, but if he could witness the result of sowing a row of aged Pea seeds, as occurs with us occasionally, I am sure he would hardly venture to urge a high temperature for germinating them. They start quicker, it is true, than in a temperate atmosphere, but so also do the thousand-and-one micro-organisms with which they are surrounded, which soon destroy their vitality; the latter, however, are possibly not present in such numbers under artificial conditions as they are in a tropical country.

The majority of tropical seeds have a vitality of an evanescent character, and to dry them is at once to destroy them; but to this there are notable exceptions. We have an illustration of this in the seeds of *Guilandina bonducella*, L. This seed is furnished with a testa impermeable to either water or air, which

probably preserves its vitality as long or longer than any other tropical seed, owing to the fact of its being "hermetically sealed" in a proper manner. *J. H. H., Trinidad, April, 1898.*

TAGETES LACERA.

(BRANDEGEE), LOWER CALIFORNIA.

A SUB-SHRUBBY, half-hardy perennial, introduced and raised from seeds by Col. John Ross, C.B. (John Ross of Blagenburgh), of Rostrevor House, Rostrevor, Warrenpoint, co. Down, Ireland. Col. Ross kindly sent a plant in 1897 to the Botanical Gardens of Trinity College, Dublin, which flowered in a greenhouse in February, March, April, and May, 1898. The flowers are small, with clear orange-chrome or yellow florets, and freely produced in lax terminal panicles, and if touched they have the characteristic odour of the French and African Marigolds; but the plant is of a much more graceful character (fig. 135). Our specimens came from Mr. Burbidge, who is anxious that all the credit of its introduction be given to Col. Ross, C.B., and he further informs us that the plant has passed through the mild winter of 1897-98 in the open in Col. Ross' Garden at Rostrevor, Co. Down, Ireland, and adds, "If one may judge from its neat and perennial habit, and its free-flowering character, it would appear to be a distinct addition to half hardy shrubby Composites, and it may be available for hybridising purposes with the annual species; or even cross-bred seedlings from itself may lead to some improvements in the size and colour of its flowers, as the plant evidently is a very free seed bearer."

METHODS OF PLANT PROPAGATION.

(Continued from p. 213.)

BULBOUS PLANTS.—In my last paper I confined my remarks to hardy or open-border plants, which, as noted, can almost be left to take care of themselves as regards perpetuation; but this cannot be said of many indispensable bulbous ornaments of our stoves and greenhouses. I will, therefore, venture to give a few simple methods of propagating them, which, to those who know, may be taken simply as reminders, while those who do not will doubtless thank me as they have done before.

Lilies.—The Lily genus may be taken first. All of these may be increased by their bulb-scales, as is proved by the good price often realised by the box or boxes of "pieces" which generally concludes an auction sale of these bulbs, especially if the varieties offered have been high-class and rare.

The scales should be bedded in sandy loam, watered in, and then placed in a moderately warm pit, when most of them will make one little bulbil, or perhaps more, at the base of the scale, which being allowed to grow for one year more, may be detached, and potted-up five or six together in a 48-pot; or in the case of the hardy kinds, be lined up in beds or borders, and merely protected in the winter by a thick layer of cocoa-refuse or leaf-mould, and left till they attain to flowering size. Lilies of the tigrinum section, especially the old-fashioned Tiger-Lily of our gardens, give us plenty of little bulbils on their flower-stems. These should be left attached till the resting-period of the parent-bulb arrives, when they may be detached, and potted or planted up for stock. *Lilium lancifolium* does not often make bulblets, but may be coaxed to do so by earthing-up the stem with some light soil, and then shortening it, so as to leave only enough foliage to keep the sap moving. Other Lilies, particularly *canadense*, *longiflorum*, and its useful variety from Bermuda, called *Harrisii*, as a rule, when doing well, make quantities of bulb-offsets, which may be removed, and potted-up in stores, or put aside in cocoa-fibre or sand, and planted up in the spring. The noble *Lilium auratum*, especially imported examples, has a habit of flowering, and then breaking up into a perfect nest of little bulbs; these should be carefully separated when the flower-stalk is ripe, and potted

FIG. 135.—TAGETES LACERA.

up or stored. *Lilium auratum* seeds very freely, especially if the grower will take the trouble to use the pollen from other flowers of the same species, and artificially fertilise the stigma. I raised many from seed when the bulbs cost 14s. each; it was then quite worth while. Allow the fruit to become so ripe that it bursts and shows its contents, then gather and lay singly in trays in the sun, when the seed will drop out easily from the seed-vessel, and may be collected and fanned to get rid of the light useless seeds, and the rest rubbed between the hands, to take off the thin part or wing, and the plump oval kernels sown in boxes or pans. If well-cared for, generally most of these will flower the third year, and not unfrequently a few choice varieties reward the raiser, the noble *auratum* *platyphyllum* and others being seed variations.

No one in England as yet, so far as I can ascertain, has tried to cook this Lily, though I read they are thus utilised in Japan. Will some one who knows divulge this, and so add to our vegetable menu?

So much for Lilies proper, though popularly most of the following subjects are called Lilies by the uninitiated. For instance, the "Scarborough Lily" (*Vallota purpurea*), so useful for its early autumn flowering, its trivial name being "purpurea," but why, I know not, unless it be from the colour of the leaf and flower-stalks, as they emerge from the crown of the bulb. This, properly treated, produces quantities of small bulbs at the base of the parent, which, at the time of repotting, may be broken off and potted-up, or nursed in pans.

A variety with large flowers, softer in colour, larger, and not so deeply crenate, as the type, with a conspicuous white centre, is known in my neighbourhood as Gilbert's variety, but was sent out as a novelty by Mr. W. Bull under the name of "eximium." This is far preferable to the old form, and makes a noble specimen, when well flowered, to associate with *Allamandas*, *Dipladenias*, *Eucharis*, &c., making a telling addition to a collection of stove and greenhouse plants in flower for autumn exhibition.

The hybrid *Amaryllis*, of which Veitch, Ker, Williams, and others have given us within the last few years so many grand examples, may all be increased in the same simple manner, and I have found that starving, both as regards manure and water, induces them to make offset bulbs, especially after they have flowered; while splitting the bulb from the base about half an inch up into four to six segments, according to its size, will also cause the production of small bulbs, but it should be done when the bulb is in full growth and vigour, without lifting it from the soil in which it is potted, the bulb being allowed to attain to its resting time before the offsets are removed.

*Crinum*s and *Pancratium*s, as a rule, make plenty of side-bulbs, and these should be allowed to grow beside their foster-parents till large enough to remove and repot. *P. fragrans* and *P. illyricum* are perhaps the most useful generally met with, but to flower these year by year attention must be given to their periods of growth and rest. With due deference to growers whom I know hold quite contrary views, the useful *Eucharis amazonica* gives better results if allowed to dry and rest, so that at least the greater part of the foliage dies down. Then is the time to take off all the small side-bulbs, and clean them to repot into some fresh hazel loam and fibrous peat, and after about three weeks or a month's rest, to put them into gentle bottom-heat, when, as soon as the pots are well filled with roots, they will generally flower.

A novel plan, culled from the new American gardening paper, *The Weekly Florists' Review*, is, I think, worth a trial on this side of the herring-pond. "After flowering (about June) the pots of bulbs are shaken out, and the single bulbs selected and planted in a warm and rich sheltered border, allowing enough space between the bulbs for cultivation and care. Early in the autumn the bulbs are taken up, and repotted firmly in fresh turfy loam. In a short time the flower-spikes will begin to push up, or this may be retarded by keeping the pots in a cool house." Allowing for difference of climate, why

should not this plan succeed in Britain, and would it not probably rid us of the mite?

Cliveia or *Imatophyllum*, of which there are now at least a score of fine varieties, introduced since *Cliveia nobilis* was sent us from the Cape in 1823, is one other bulb that increases regularly and surely if well cared for, and kept clean from mealy-bug and other pests. The side bulbs may be removed by a sharp knife as soon as the flowering period is over, and potted and kept quiet for a while, and then encouraged to grow by the aid of heat and stimulants. When they cease to produce more young leaves from the crown, withhold water for a while, and then the flower-spikes will soon appear emerging flattened from between the handsome curved leaves.

If assisted by fertilising the flowers by pollen taken from other individuals, *Imatophyllum miniatum* seeds freely, producing deep plum-coloured or red drupes. When these are quite ripe, open them and take out the solitary seed, and sow in deep pans at once. They will germinate the following spring, and the young plants will generally follow the third year. I raised a few good varieties in this way, which have passed into trade through various channels.

There are many more bulbous plants, as *Hæmanthus*, *Daubenyas*, *Cyclobothras*, or *Calochorti*, but these are so seldom seen outside botanical collections that it would be of little use to indicate their method of propagation, while the *Calochorti* are imported every year by some firms and sold by auction at the Mart; sad to say, my experience of them is that they flower, and then gradually disappear, a circumstance much to be regretted, as some are very beautiful, and well deserve their common name in California, "The Shell Lilies." If seeded, would the progeny raised from this be more robust in constitution, or are our winters too wet for them? *Experience*.

(To be continued.)

CULTURAL MEMORANDA.

SOWING SEEDS OF ANEMONE FULGENS, HORTENSIS, &c.

To sow in shallow boxes filled with light loamy soil, and to transplant, is perhaps better than to sow in a bed in the open. The seeds after being rubbed in sand to separate them, should be dibbled in at 1½ inches apart, and slightly covered with fine soil; the boxes may stand in a cold frame till the plants are large enough to be transferred to the nursery-beds. After the seedlings are established, water should be copiously applied in dry weather, and at intervals liquid manure may be afforded. A bed for these plants should be heavily dressed with decayed manure, and its position should be rather moist than dry, and the soil of a good depth. In cold and heavy soils, it is good practice to mix leaf-mould and sand with the staple, in the upper part at least.

Anemone fulgens may be advantageously flowered in pots, but it may not be subjected to a high temperature. Kept free from frost in cold frames during winter, the tubers flower very early, and are very useful for furnishing flowers for cutting and other purposes. *H. Markham*, Northdown, Margate.

LARIX LYALLI.

THE illustration on p. 357 represents a group of the alpine *Larix Lyalli* growing near the shores of Lake Agnes, in one of the wildest parts of the Rocky Mountains of Southern Alberta, at an elevation above the sea of nearly 7000 feet.

Larix Lyalli, which is distinguished from the nearly related *Larix occidentalis* by its tetragonal leaves and tomentose branchlets, was discovered in 1860 by David Lyall, the surgeon of the British Commission which marked the northern boundary of the United States west of the Rocky Mountains. It is a small tree, rarely seventy-five feet in height, with a trunk generally 18 or 20 inches, but occasionally 3 or 4 feet in diameter, and remote, palmately divided, exceedingly tough, persistent branches

thin, dark red-brown scaly bark, cones from 1½ to 2 inches in length, with conspicuous exerted purple bracts and scales, fringed on the margins with matted white hairs. *Larix Lyalli* grows only near the timber line, at elevations between 4,500 and 8,000 feet above the level of the sea, and is distributed from Southern Alberta and the interior of Southern British Columbia southward along the Cascade Mountains, and through northern Washington to Mount Stuart, one of their eastern spurs at the head of a fork of the Yukima River. In Alberta this alpine Larch grows on steep slopes and benches, usually facing the north, either singly or in groves of a few hundred trees, and alone or mixed with Engelmann's Spruce. In the region where the boundary between British Columbia and the United States crosses the Cascade Mountains, and where it was probably discovered by Lyall, *Larix Lyalli* is scattered at an elevation of about 6000 feet above the sea, over undulating grass-covered table-lands, where its associates are *Pinus albicaulis*, *Abies lasiocarpa*, and *Tsuga Pattoniana*. On Mount Stuart, where it finds its most southerly home, the trees form a straggling line along the upper margin of the forests, or occasionally small irregular groves up to 8000 feet above the sea. *C. S. Sargent*.

THE PRINCIPLES AND PRACTICE OF GRAFTING.

AMONG the methods which the gardener adopts for re-producing any given species or variety of plant, that of "grafting" holds a most important place. It is especially useful in the propagation of many trees and shrubs to which the application of other methods of propagation is found too tedious or difficult. Fruit-trees, Roses, *Rhododendrons*, *Hollies*, *Conifers*, various deciduous trees and shrubs, &c., may be multiplied in this way.

Take the concrete case of the Apple-tree. The numerous varieties of the Apple are commonly grafted, either upon the common wild Crab, or the Paradise-stock. The process, to take the simplest form of grafting, is the following: an oblique and perfectly smooth cut is made opposite a dormant bud or eye, severing thereby the upper part of the stock-plant; a similar oblique clean cut is made on the lower end of a twig of last summer's growth of the variety to be grafted, and in the same position; these two cut surfaces are then applied one to another, so that the two easily fit and coincide, leaving no portion of the cut surfaces exposed. They are then tied firmly together with bast, and finally, wax is smeared along the sides in order to prevent the entrance of either moisture or dry air. The operation should be performed either during the winter or the early spring. At these seasons of the year the plant is practically in a dormant state, that is to say, no growth is taking place, for no sap is as yet passing actively through the tissues, and the assimilation of food has ceased.

STRUCTURE OF THE WOOD.

It is here necessary to describe the structure of the stem of the Apple, in order to make clearer the following remarks. Starting from the outside, as seen in a transverse section of the stem, there is the bark, consisting of a small quantity of dead corky-tissue. Next within this is the cortex, consisting largely of living green cells called parenchyma, which have the same function as the green cells of the leaf, but the cortex, in the older condition of the stem, becomes entirely replaced by cork. The tissue succeeding this is the bast or phloëm, containing elongated narrow cells called "sieve-tubes," which are of great importance as the conductors of the elaborated sap coming from the leaves, and of very small and short "companion-cells," with dense protoplasmic contents intimately attached to the sieve-tubes laterally. Besides these are other larger parenchyma cells scattered amongst the sieve-tubes, and also the cells of the medullary rays, containing living contents and forming bands running in a radial direction from the pith to the cortex. But the tissue which occupies the greatest portion of the diameter of the stem is the wood, the most conspicuous and important elements of which are the vessels, for they are the chief agents in the conduction of the water through the stem.

With the exception of the youngest elements at the outer periphery of the wood, they are quite dead and lignified, being merely passive conductors of the sap; their walls, with the exception of the

innermost spiral vessels, are studded with numerous bordered pits. The other dead elements of the wood are the fibres, which are greatly elongated, thick-walled woody elements with small pits in their lateral walls, and very tapering ends. But there may also be present another kind of fibre, called the fibrous cell, possessing living contents, thicker walls, and fewer pits; these fibres, of whichever kind, are the principal strengthening elements of the wood. Numerous living, thin-walled parenchyma-cells, with protoplasmic contents, are found scattered in the wood, usually in immediate connection with the vessels, in

with conspicuous protoplasmic contents. The centre of the stem is occupied by the pith, consisting of short parenchyma-shaped cells with thin walls; many of these cells are living, and contain protoplasmic contents. Others may be dead, and may then be slightly woody in texture, and possibly take some part in the conduction of the sap.

Continuity of Protoplasm.—I may here mention an important fact in the minute structure of the stem; all the living cells, in whatever part of the stem they may occur, are in intimate communication

and as little difficulty as possible to the plant in bringing about the union of the two surfaces of stem. As soon as, under the genial warmth of the spring sun and moisture, the sap gently begins to stir both in the stock-plant and the graft, both of these will straightway begin the work of healing the fearful wound which has been made in their respective stems. The living parenchyma-cells of the cortex, bast, cambium, wood, and pith, on either side of the wound will begin to divide up, chiefly by transverse walls, so as to bring the two surfaces of mutilated cells into intimate contact with each other; the protoplasm will probably also exert its cellulose-forming power by bridging the gaps between the broken cell-walls of the opposite surfaces; parenchymatous-tissue, known as wound-callus, will be formed outside the two applied surfaces, at any point where contact of exposed tissues with the air occurs, the outermost cells of this tissue becoming corky.

When this complete union of the two surfaces of the stock and the graft respectively, by means of the direct continuity of their cell-walls, has been accomplished, is this the whole of what has to be said? What does this continuity of the walls imply? It implies also the continuity of the protoplasmic contents of the cells of the stock and the graft, by means of those minute protoplasmic threads traversing the cell-walls already described above. It is through the agency of these tiny protoplasmic channels that a real and vital union is effected between the living tissues of the stock and the graft, in just the same way as a real and vital union exists between all the living tissues of the stock or the graft, considered as separate units.

As regards the dead elements of the wood, the vessels and fibres, owing to the fact that they contain no protoplasmic contents, the union between the opposing surfaces will be a purely mechanical, and thus far less complete, one, but will no doubt suffice for the uninterrupted passage of the sap from the stock to the graft.

The protoplasm is the seat and origin of all the phenomena of plant life; it is there that the life-processes take place, of nourishment, respiration, and growth. In the protoplasm, as the centre of vitality, and the pivot on which all the complex incidents of life turn, reside the whole character and idiosyncrasies of the plant. From the fact that this vital fluid forms one continuous network through the living tissues of the plant, it follows that the plant is a single individual in the truest sense of the word; that all the tissues, and all the cells composing the tissues, have characters in common, and there is not a single cell which may be said to be discrete, and to possess an entirely independent character of its own. It is true that certain tissues are differentiated to form structures possessing functions very different from other tissues of the same plant. Yet these differences are in reality but superficial and apparent, an undercurrent of common character running through them all. The ovule may often develop as a leaf, the stamen as a petal, the petals and sepals as leaves, or the whole flower as a vegetative shoot, and in the early forms of vegetable life, stem, root, and leaf are one and the same organ. We have even several instances, familiar to every gardener, where a whole plant may develop from a leaf, as in *Begonia*, *Streptocarpus*, *Ferns*, &c. The secret of all this is that the protoplasm, which is the fundamental seat of the whole bundle of characters and peculiarities of the plant, passes freely and openly from cell to cell through the whole length of the plant from the tip of the root to the embryo enclosed in the seed.

Reciprocal Influence of Stock and Scion.—When a graft or "bud" has "taken," i.e., when it has become vitally connected to the stock, the result will be a mingling, in a greater or less degree, of the protoplasmic substance of the two, so that, on these grounds, we should expect to find an influence working, in one direction from the stock upon the graft, and in the other from the graft upon the stock. But this mutual influence, though it must exist, is, in the majority of cases, but little apparent, inasmuch as we see the grafted shoot as it unfolds its leaves, shoots, and flowers, showing characters peculiar to itself, and none of those peculiar to the stock. The influence of the stock upon the graft must therefore, in these cases, we conclude, be very slight and inappreciable. On the other hand, there are cases known where this influence is very much more pronounced, and where the characters of the stock appear very conspicuously intermingled, in different ways and in various intensities, among those of the graft; an example of this is seen in the familiar graft-hybrid, *Cytisus Adami*.

The conditioning factors, in all cases, of the in-

FIG. 136.—*LARIX LYALLI* IN THE ROCKY MOUNTAINS. (SEE P. 356.)

the conducting function of which they probably play a not insignificant part; these elements are usually quite short, and occur in vertical rows of four at the sides of the vessels. The cells of the numerous medullary rays, with their living protoplasmic contents running radially through the wood, must be of great importance in supplying the wood, parenchyma-cells, and the young developing peripheral wood, with nourishment received from the bast and cortex. Situated between the wood and the bast is the generative layer, the "cambium," which is the seat of the formation of the new layers of wood and bast formed by it to the inside and the outside respectively; it consists of slightly-elongated narrow cells,

with each other by means of their protoplasm, which, in the form of numerous extremely minute threads, passes freely through the cell-walls; in this way, throughout the plant, open channels for the passage, probably, both of food substances and of stimuli through all the living cells, exist—a recent histological discovery which must be considered as of real practical significance.

Now the reason why especial care is taken that the incisions made both on the stock and on the graft shall be perfectly smooth and even, the work of an adequately-sharpened knife, so that no sinuosities in the surfaces, and no mangling of the tissues shall occur, lies in the endeavour to cause as little strain

fluence of stock upon graft, and *vice versa*, are very occult. I will here throw out but one suggestion, viz., that in those cases, the majority, where no perceptible influence from the stock occurs in the grafted shoot, the cause may possibly be found in the fact that the protoplasmic substance of the grafted shoot is more vitalised, more active, and stronger than that of the stock, and this would naturally result from the fact that as soon as the graft begins to form its leaves and twigs, which would occur as soon as the sap began to flow, those of the stock are all carefully and cleanly stripped off; hence the food-supply for the protoplasmic substance in the stem of the latter is almost entirely cut off, which must inevitably devitalize it, and incapacitate it for any influence as the representative bearer of the characters peculiar to the stock. Its future sustenance must come chiefly from the activity of the grafted shoot. This, however, is a mere suggestion regarding a possible factor in the case. The most important causes may be more hidden and obscure.

As regards the influence of the graft on the stock, this has also, in those cases where it has had an opportunity of manifesting itself, been observed. But in most cases no such opportunity is afforded, for the stock, as soon as the graft commences growth, is denuded of its leaves and shoots.

Supposing the grafting to be performed in the later spring or summer, however, when the sap is actively and rapidly passing through the tissues of the plant in great quantity, what will happen? In the first place, the redundant sap, on reaching the cut surfaces, and finding its habitually smooth course partially interrupted (however tightly the two surfaces may appear to be mutually applied), will tend to accumulate there, and swamp both the woody and the living tissues with over-abundant moisture, which would doubtless interfere considerably with their ordinary functions, causing some injury, and even death, to the cells, and certainly prevent the requisite cell-division, and the formation of the lateral wound-callus, without which the graft could not "take." In the second place, even supposing there was a chance of the graft "taking," the sap would have a tendency to push the buds of the stock below the grafted portion, so that extra labour would be required to constantly keep nipping the young wild shoots as they grew out; otherwise, if allowed to sprout, they would prevent the proper passage of the sap to the graft, which would, in consequence, rapidly become exhausted. Again, even if these wild shoots were properly suppressed, and the sap effected a thorough passage into the graft, the buds of the latter would rapidly shoot forth, and tend to draw too large a quantity of sap across the wound before it had become thoroughly healed—a state of things which would considerably interfere with that process. This rapid shooting of the buds would also tend to exhaust too early the energies of the young grafted plant—a circumstance which would injuriously affect its later growth.

A point of great importance in grafting is the selection of the proper kind of grafts. These should always be taken from last year's shoots, and not from older ones of the previous year, for the younger the shoots the greater amount of actively-growing tissue do they contain, and consequently the greater their vigour; and the greater the number of living cells present, the more intimate and complete will be the union of the two surfaces of the graft and the stock respectively. But the part of the stock on which the graft is inserted need not necessarily be of the same age as the latter—it is often somewhat older; but if both stock and graft contain a sufficient amount of youthful vigour, this is all that is required. *W. C. Worsdell, F.L.S.*

(To be continued.)

FORESTRY.

TREATMENT OF PLANTATIONS WITHOUT REGULAR THINNING.

In 1895 I described the 20-feet cuts made in May, leaving 80 feet of unthinned trees between each two cuts. No large trees have died since, and none has been blown down. The Beech and Silver Firs planted in November, 1895, in the openings, have made a good start, and will soon cover the ground. My son, who has been in the Indian Forest Service for ten years, has taught for several years in the Imperial Forest School, Dehra Dum, India, and has kept up his knowledge of German forestry, spent four days with me at Tregonnett. We worked through two of the blocks into which the plantation is divided

by the roads and the 20-feet cuts, cutting down the slender trees that whipped the others from the strong north-west wind then prevailing, and removing any that were injured by squirrels, or showed signs of Larch canker, which could not certainly be diagnosed, as it was too early for the spores to appear. Where two or more trees stood 4 feet apart, one was cut down. The trees left afford as much leaf canopy as Larch will maintain, and the work improved the appearance of the plantation so much that I concluded to hire men, and give the thick parts their first thinning, except the vistas that were cut 12 feet wide in 1877, and those nearly at right angles to the above made in 1881-2-3, the last 16 feet wide. The conditions are so different in our mild and somewhat damp climate of Cornwall, without great heat in summer or cold in winter, from those prevailing in Germany that a different mode of treatment may produce better results in Cornwall than would result from German methods. Seven acres is a very small area to work on. If I had a larger area of plantation, I should treat it on what I understand to be the late Mr. Enys's principles.

With regard to the German idea of keeping a plantation close throughout with unbroken leaf canopy, so as not to allow the carbonic acid gas to accumulate near the surface of the ground, I do not perceive how the roots or trunks of the trees are to absorb it. It seems to me that the constant circulation of air by day and night, whether there is any or no wind, caused by the difference of temperature in the open spaces from that in the thick parts, is better calculated to enable the leaves of the trees to absorb carbon from the atmosphere as the air passes, and so promote the deposit of carbon under the bark, and encourage the growth of timber.

We have cut a great many railing-poles this year, the forty-first since it was planted, and they have done their work so well in killing the branches on the trees now standing that one rarely finds a branch on the Larch an inch in diameter, and they are beautiful straight poles, so the time has come to encourage them to increase in bulk and grow fast. Silver Fir and Beech seedlings are springing up freely in places since the 20 feet cuts were made.

It is intended to underplant with Beech next autumn. When that has been done it will be perfect. *H. R., Plymouth.*

THE WEEK'S WORK.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

Peach and Nectarine-trees.—The first thing to be done after the last fruit is gathered is to remove the wood which has borne fruit this season, and that which is not required for next year, and to nip the points of all side shoots back to two leaves. Endeavours should be made by means of a bit of lath, &c. and a bast tie to keep all the young shoots straight, and in their proper places. After these matters are attended to, afford the foliage with a syringe or engine, a washing, using considerable force in doing this, but not so as to tear the leaves. During the summer let red-spider be kept in check with an occasional use of the syringe applied in the afternoon; afford a thorough application of water to the roots as often as the soil shows signs of dryness, and do not omit full ventilation night and day, excepting during thunderstorms. Brown scale sometimes infests the wood and leaves of the Peach, and a good remedy against it is to syringe the trees occasionally with soap-suds made with soft-soap at the rate of 2 ozs. to one gallon of water. Peach and Nectarine-trees in pots, after the fruits are cleared off, require much the same kind of treatment as the foregoing, and water is required at the root much more frequently. If red-spider, aphids, &c., attack the trees, it is an easy matter to lay them on their sides and wash them clean with a syringe and soap-suds, taking care to wet more especially the under-sides of the leaves.

Cherry-trees, after fruiting, need similar attention to the Peach, and being apt to infestation with black aphids, fumigation or vaporisation should be resorted to. The fruit keeps in good condition on the trees for some time after it is ripe if the Cherry-house be kept dry, and it is freely ventilated. It will be necessary in country gardens to put nets over the ventilators, in order to prevent the ingress of blackbirds.

Plums.—When stoning is completed, if it be thought desirable to ripen the fruits early, the temperature of the Plum-house may rise to 90° late in

the afternoon; and an hour or two later the top ventilators may be opened a small space, and remain so all night. During the night the warmth may not exceed 65° nor go below 60°, and on dull days 70° by means of fire-heat is high enough; and with sun-heat 80° to 85°, increasing the amount of air when 70°, 75°, and 80° are indicated. Syringe the plants well when shutting-up the house if the day has been fine; and in dull weather it will suffice to merely damp the floor and the borders. After stoning, the Plum requires more water at the root than at other times, but at no time during growth should the soil lack water. Bearing-trees for late supplies should have their fruits thinned for the last time; completing the work before stoning commences. As often as may be required pinch the points of the lateral shoots, this having the effect of forming fruit-spikes out of what are merely wood growths; and endeavour to secure uniformity in the heads, filling bare spaces, &c. Make but little use of artificial heat, only warming the hot-water pipes on wet days and cool nights, so as to be enabled to maintain buoyant air in the house, and a somewhat free admission of fresh air by night and by day, more or less in accordance with the state of the weather. Syringe the trees in the afternoon if the day has been warm and fine.

HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Tomatos should be planted as soon as they are hardened off in a proper manner, that is, not hurriedly, and this is more particularly necessary with plants which may have been grown in shady houses. I do not recommend the use of manures when setting out Tomato plants, as it induces a strong growth in a showery summer, and is seldom productive of good results. After a crop of fruits has set, manure may be advantageously applied in some concentrated form, and it will materially increase the weight of the crop. On Tomato plants grown out-of-doors, lateral shoots should be suppressed, and the main-stem only allowed to develop, keeping it fastened to the wall or other support as it grows. In warm summers the Tomato does well trained to 5-foot stakes in the open quarters, but only when the plants are strong when put out, and the position is a warm one. Certain varieties found in the seed-lists are better adapted to this mode of culture than others, and it is advisable to select such varieties rather than plant indiscriminately. The small-fruited varieties are extremely prolific when planted outside, and they ripen very well provided the season is moderately warm.

The Apricot.—The fruits should now be finally thinned, the larger varieties such as the Peach and Moor Park being left at an average distance of 9 inches apart, and the smaller at 6 inches. If the fruits are not disposed equally over the tree, they may be left more thickly where they are most abundant, but not closer together than 3 inches for the smaller fruited varieties, and 6 inches for the larger ones. The fruit when approaching ripeness are easily injured, and if they are crowded against each other decay is soon set up. If an Apricot-tree be over-cropped in one year, it generally fails to bear much fruit the next year; the gardener should therefore endeavour to avoid this misfortune by a timely thinning of the fruits. Woodlice sometimes commit much havoc on the fruit when it begins to change colour, and every precaution should be taken to avoid this by trapping them in bits of Bean-stalk and Bamboo—in fact, little tubes of any kind of material stuck about behind the branches; and the old familiar flower-pot trap, stuffed with damp hay, should be laid in numbers under the trees. Whatever is set as a trap should be examined every day, and the creatures caught destroyed. This season the growth of the Apricot has been slow, and summer-pruning will have to be deferred until the wood is in a more advanced stage. Trees which are heavily cropped may be assisted with weak liquid-manure afforded occasionally, and a mulching of farmyard manure over the roots if dry weather should set in.

Grafted Fruit-trees.—The clay round the grafts should be examined, and all cracks closed with a thickish mixture of clay and water, applying it with a stiff brush, it being a matter of importance to keep air and moisture from the point of union till the latter is perfected, the apex of the clay mass being very carefully closed round the scion. Last year's grafts and buds will in most cases need fastening to the snag that was left on the stocks in the latter case, and to a stick thrust-down close to the stock in the former.

Unless a stock is very weak, all of the emitted shoots may be rubbed off; if weak, then retain a few, which should be allowed to grow 2 inches, and then be pinched at the point, rubbing off all others. The shoots coming from the scion should have their points nipped out early, excepting those which are to be the main branches, which must be allowed to go away unrestricted.

Pears.—Many fruits are dropping at Belvoir, owing to the trees having been infested at the flowering time with a small fly, *Diplosus pirivora*, whose eggs are deposited in the blossoms, and such early varieties as White Doyenné and Windsor are suffering badly. The fly does not, however, confine its attentions to any particular variety. Maggots about one-eighth of an inch long soon hatch out, and begin at once to feed on the inside of the young fruit, causing decay, and the fruit soon drops. These dropped fruits should be very carefully collected without delay, and burnt forthwith. It is very likely that doing this every year would in course of time greatly diminish the numbers of the pest.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

Dendrobiums.—*D. Bensoniæ* and its variety *xanthinum*, now passing out of flower, should be given fresh compost, if needful, as soon as the young breaks are a few inches high and they are emitting roots. The same may be said also of *D. Parishii*, *D. P. polyphlebium*, *D. P. Emerici*, and *D. P. albens*. These species require but a very thin layer of compost and sphagnum-moss alone, or peat and moss may be used. Suspend the plants during growth close up to the roof-glass in the hottest house, and keep them well supplied with moisture. *D. Bensoniæ* is reputed to "deteriorate" after a few seasons, but at Burford we have a strong plant which has been here for some years, and it makes larger pseudo-bulbs and blooms freely each year. Afford the plant a hot and moist atmosphere during growth, and when this is finished expose to full sunshine and withhold water. Our plant has not received a drop of water at the root since last September, and the bulbs are still plump and fresh. It now bears about three dozen flowers of pearly whiteness, on the last made pseudo-bulb. Instead of resting the base of the plant upon the surface of the compost when repotting it, keep the soil on a level with the rim of the pot or basket, and raise the leading pseudo-bulbs considerably above it. The base of the young growth upon our plant is quite $1\frac{1}{2}$ inch above the compost. Keep the potting material rather dry until the new roots have obtained a firm hold, then water may be afforded in small quantities and gradually increased. During the resting period the temperature of the house may fluctuate between 60° and 70°, but now that growth has commenced it should be given the same temperature as that advised for *D. Phalenopsis* in a previous calendar. *Dendrobium Falconeri giganteum* is a species similar in some respects to the preceding, its young breaks commencing to push up as the flowers expand. Repot it in the same manner as *D. Bensoniæ*, but do not grow it in a very hot house, a warm and moist position in the Cattleya-house suiting it better. *D. infundibulum* and *D. Jamesianum* may also be repotted as soon as growth recommences. Place the plants at the warm end of the Odontoglossum-house, and afford abundance of water throughout the growing season.

Odontoglossum citrosimum.—Re-basket plants of this species as they pass out of bloom, and suspend them from the roof; and as the plant makes but few roots, use only a small receptacle. Pot very firmly with peat and sphagnum-moss; as by making the compost firm, the pseudo-bulbs retain their plumpness longer during rest. Suspend the plant close to the roof of the Cattleya or Mexican-house, and if it can be placed near to a top ventilator, all the better. For a week or two after repotting, keep the compost merely moist, but after that time gradually increase the supply, and when in full growth afford water copiously.

Various Species.—*Renanthera (Vanda) Lowii*, now growing freely, may be placed with such species as *Angraecum sesquipedale*, *Vanda Sanderiana*, &c. The rare *R. Insechootiana* appears to thrive best when grown in small pans, potted only in crocks, with a thin surfacing of sphagnum-moss; and a place near to the roof on the lightest side of the Cattleya-house is the best position for it. A similar position is suitable for such plants as *Chysis bracteosa*, *C. aurea*, *C. Limninghei*, *C. Sedeni*, and *C. Chelsoni*; these

plants, being now in full growth, should be afforded copious applications of water. Towards the autumn they should be removed to the sunny side of the East Indian-house, to complete and mature their growth and pseudo-bulbs. The following plants—*Oncidium Marshallianum*, *O. concolor*, *O. olivaceum*, *Lawrenceanum*, *O. superbiens*, *O. dichromum*, *O. undulatum*, *Epidendrum vitellinum majus*, *Miltonia vexillaria*, and the numerous varieties of *Odontoglossum* which are now in bloom, should be relieved of their flower-spikes as soon as possible; over-flowering being frequently the cause of the deterioration of so many of these beautiful species.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Dahlias.—Put out the plants at once, there being little danger now of frost occurring. The Dahlia requires a deeply-dug and richly-manured soil, but this should have been prepared previously. Place a stout stake to each plant at the time of planting, and secure the plant loosely to this by tying. As slugs and earwigs are very destructive to Dahlias, it is well to place a ring of soot or lime at a little distance from the stem of each plant. This precaution should be renewed every few days, or oftener in case of rain. The best and simplest method of entrapping earwigs is to place a small pot in an inverted position with a little hay in the bottom of it, on the top of each stake. Examine these every morning, and destroy as many earwigs as may be found. If the soil is dry at the time of planting, a good watering will be necessary when the work is done, and the roots of all the plants should be moderately moist before being put in. If the plants are to be cultivated for furnishing exhibition blooms only, all the weaker shoots should be removed, and the number of flower-buds reduced. Frequent application of liquid-manure will be helpful as the season advances. Plants intended for garden decoration should be placed 3 feet apart each way, and the removal of fewer shoots will be necessary. For cut-flower purposes, the Cactus and Pompon varieties are best; the single-flowered varieties have lost favour during late years.

Sub-tropical Plants.—*Eucalyptuses*, *Ricinus*, *Nicotianas*, and other similar habited species, should be planted in a sheltered site, or the damage wrought by rough winds will be great.

General Work.—*Begonias*, whether tuberous or fibrous rooted, should be planted at once. If strong sunshine is prevalent at time of planting, it will be advisable to shade the plants for a few days with branches. A covering of Coconut-fibre over the soil is an advantage, as in preventing the flowers and foliage becoming splashed during showery weather. Bedding of every description should be completed without delay.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Crotons.—Small plants, whilst they are now making growth, should be repotted before they become pot-bound. Let the plants be grown fully exposed to the sun, not placing them close together, but allowing ample space to each, so as to enable its foliage to develop fully, and use the syringe freely every day, twice, or oftener; and close the house early in the afternoon, the Croton delighting in high warmth, and much moisture in the air. The heads of such of the plants as have grown too tall may be bound round with moss, as previously advised, into which they will soon put forth roots, and may then be cut off and potted. The well-coloured side-shoots may also be taken off, inserted in thumb-pots, and plunged in a close, moist propagating-frame, and shaded from the sun. Plants which are growing freely may be afforded manure-water and clear soot-water occasionally.

Acalyphas.—Few kinds of stove plants are more usefully decorative than these, for they may be kept in a living room for a considerable time without injury if ordinary care be afforded. To ensure strong, brightly-coloured plants, it is essential to grow them in brisk heat. In the early stages they are susceptible of injury by scorching, if fully exposed to the sun; it is, therefore, necessary to gradually expose them to full sunlight. Any plants that become leggy may have the tops cut off, inserted in small pots of light soil, placing these in a strong moist heat. If the old plants are out-back and kept somewhat drier at the roots for a time, growth will be renewed, and they will in time make presentable plants.

Caladiums.—Advanced plants should be carefully hardened off before placing them in the cool conservatory, which they will help to make gay for some weeks. Those plants which are not very forward should be kept in a close, warm, moist house, and when growing freely weak manures may be afforded them.

Allamandas.—Large plants growing in pots will now be showing flower, and to have these of fine size plenty of readily available plant-food is necessary. It is good practice to place a thick layer of manure on the surface of the soil, and to afford weak liquid-manure every time when water at the root is needed. Repot young *Allamanda* plants which may be allowed to increase in size, and let them grow with their foliage fully exposed to the sun; and afford them a compost consisting of good fibrous loam six-sevenths, decayed manure one-seventh, and plenty of sharp sand. Shade will only be needed for a few hours during the hottest part of the day, after a large number of the flowers are expanded. Plants that have been trained round four or five stakes, and are sufficiently hardened off, may be removed to the cool conservatory, standing the plants where cold draughts will not reach them. With careful treatment, such plants will continue to produce flowers for a long time.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

Cabbage and Coleworts.—At about this date according to the lateness or forwardness of the locality, more seeds of Cabbage and Coleworts may be sown for the purpose of affording plants for setting out on land which will have been cleared of Potatoes and Turnips, &c. Advantage should be taken of showery weather to plant Cabbages, being careful to make the soil firm about them, and to mould up growing plants. Let the Dutch-hoe be freely used among the plants set out during April and May, and remove the remains of the crops of spring Cabbages. I always pull up Cauliflowers and Cabbages, when taking the heads for consumption, both being exhausting crops; and to leave the roots in the soil is to make the loss of plant food the greater.

Asparagus.—It will now be a question with many when to stop the removal of shoots from the plants. The exact time will depend on the part of the country; in the south, the middle of the present month is late enough, and certainly no more cutting should be done if the roots are going to be forced, as the plants must have time to mature their growth. As a help to this end, first handweed the beds, then afford a dressing of agricultural salt and bone-meal during showery weather, and should a spell of hot and dry weather set in, apply water and well diluted farmyard liquid-manure frequently. It is advisable when the stems reach 4 feet in height, to afford them support against the wind; and should the plants be arranged in solitary rows, stout stakes should be driven into the ground 10 to 12 feet apart, and tarred twine stretched from end to end of the rows and secured to the stakes, and the Asparagus stems securely tied to the twine with common bast. Another method is to place Pea-sticks among the plants in the same manner as is practised with Peas.

Endive.—Endive is a good substitute for Lettuce when the latter becomes scarce in the autumn, and at this date seeds of the curled and Batavian varieties should be sown thinly in drills 1 inch deep and 9 inches apart, on well manured land. The plants should be thinned out according to variety, from 6 to 9 inches apart in the rows, the thinnings being transplanted into beds of rich soil. Endive is a plant which should receive plenty of water in dry weather, or it will soon bolt, more especially the early sowings.

Herbs.—All seedlings raised in heat, if properly hardened off, viz., pot Marjoram, Sweet Basil, Thyme, and Sage, should now be planted in the herb border. Keep Spear Mint and Tarragon, Chives and Sorrel, in a fit state for use by regularly cutting the longest shoots and oldest leaves, as the case may be, for kitchen use. The herbs which were sown in the open border will need to be thinned to 6 to 8 inches apart, and the border kept quite clean and free from weeds. Let the labels attached to each kind be renewed, and the names thereon made legible, in order to prevent mistakes when cutting herbs for drying or for daily use.

Salading.—Make sure of having a constant supply by sowing Radishes, and Mustard and Cress, at short intervals of time; seeds of Lettuce being sown during this month.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, JUNE 11	Royal Botanic Society, General Meeting.
TUESDAY, JUNE 14	Royal Horticultural Society's Committees. Eastbourne Horticultural Society, Meeting.
WEDNESDAY, JUNE 15	Yorkshire Horticultural Fête (three days).
THURSDAY, JUNE 16	Linnean Society, Meeting. Rose Shows at Colchester and Isle of Wight (Carisbrooke).
FRIDAY, JUNE 17	Royal Botanic Society (Lecture).

SALES.

TUESDAY, JUNE 14	Orchids, by order of Mr. William Bolton, at Protheroe & Morris' Rooms.
WEDNESDAY, JUNE 15	Orchids at 39, Northend, Croydon, by Protheroe & Morris.
FRIDAY, JUNE 17	Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three years, at Chiswick.—60°-7°.

ACTUAL TEMPERATURES:—

LONDON.—June 8 (6 P.M.): Max., 69°; Min., 56°.
PROVINCES.—June 8 (6 P.M.): Max., 63°, S. E. England; Min., 51°, Shetlands.
Dull, warm, close; some rain.

Damping-off of some Seedlings and Cuttings. THIS troublesome and often disastrous occurrence may be averted in great measure by affording the seed or cutting-pots and pans as much ventilation as is consistent with safety. In the case of cuttings liable to damp off, besides wiping the bell-glasses or hand-lights dry every day, if say, an 8-inch cutting-pan, or a small 32-flower-pot be employed, a large 60-pot be sunk in it, top downwards and resting on the crocks, and in the case of a 48-sized pot a small 60, or a long Tom of about the same diameter—that is, a pot one-a-half times as deep as it is broad, be placed in the middle, as in the former case, much loss will be averted. These sunken pots serve two purposes, they preserve a space free from plants and cuttings, thus aerating the centre of the mass where damping always begins and is greatest; and they tend also to the same end by accelerating the drainage of the contents of the pan or pot, just where the moisture is apt to be greatest; and lastly, in the case of cuttings, early rooting is favoured owing to the increased degree of warmth imparted to the soil, and the more suitable degree of moisture preserved in it where the basal part of each cutting rests. One more matter often overlooked now-a-days: a fine-spouted watering-can should be in more regular use among seedlings and cuttings, and especially in propagating-frames, resting on hot-beds of stable-manure and leaves, than the fine-rose watering-can. The spout should be slightly bent downwards, and have an orifice not larger than a crow-quill, with which it is possible to afford water to cuttings and seeds without wetting the leaves

or stems. Where a small pot is sunk in a pot or pan it is usually sufficient for all needs to pour water gently round the outside of this and the inner rim of the pot or pan.

In the case of very small seeds, and of seedlings that resent overhead watering, and where dipping in a vessel of water is apt to cause water-logging of the soil, the seed-pans should be placed in larger ones, and the space between the sides and bottom filled with fine sand. This sand, if maintained in a moist state, and the pan be covered with a sheet of glass, or what is better till germination has taken place, a flat roofing-tile (not a slate, as moisture condenses on this and drops on the soil sometimes detrimentally), replacing it with a piece of glass when the plants show, will render unnecessary the application of water after the first one till the seeds have germinated, and probably for a week or two later. It is an excellent procedure for Chinese Primulas, Cinerarias, Calceolarias, Begonias, Lobelias, Nicotianas, &c. Lisianthus Russellianus is a pretty blue-flowered Gentianad, but seldom seen now, has extremely minute seeds which, if sown in sandy-peat and leaf-mould, and kept moist and cool, germinate inside of four weeks. It is a subject which, when it comes above ground, should be often wetted with a fine rose-can. The seed-pan may, however, be placed inside a larger one, for the reasons stated, and because affording water to the soil is very apt to carry the seeds over the edge of the pan, or at the least to displace them. It is a plant that germinates with more certainty if a mild bottom-heat be applied; and mild top-heat suits it in the early stages of growth.

The Crystal Palace Fruit Show

The autumn fruit show at the Crystal Palace under the auspices of the Royal Horticultural Society, is always so fine an exhibition of British-grown fruits, more particularly of hardy varieties, and its influence so appreciable in the direction of establishing a high standard of quality in Apples and Pears, that we cordially welcome the schedule for the current year, now to hand.

In accordance with previous announcements, the coming show will be opened on September 29, and will continue during the two following days. We do not observe any reference in the schedule to a conference in connection with the show; it would appear, therefore, that this interesting and important feature of previous exhibitions is to be omitted from the programme. The question of hardy fruit cultivation in this country, it may be urged, has been repeatedly discussed in its relation to site, soil, methods of cultivation, selection of varieties—in all its aspects, indeed, that there may be little new to say upon the matter. Market salesmen have also spoken in great detail of their experience in fruit distribution, with a view to persuading growers for market to so gather, grade, and pack their produce that it may realise the best possible prices, and successfully compete with imported fruits which are placed before consumers in the most tempting fashion. Still, we suppose that until all this precept has been reduced to practice, it remains for those desirous of furthering the interests of fruit-culture to keep pegging away, hammering truths, that most of us already well know, into the minds of the men actually engaged in fruit-cultivation, but whose ears are unwilling to hear advice that may call for the abandonment of methods inherited from their grand-

fathers. The preserving of fruits by evaporation has been recommended as an antidote to the ruinous prices fruit is sometimes sold for in time of a glut. The simple principles of the method are well understood, at any rate by a number of cultivators; but, except in a very limited degree, they remain unapplied. This very regrettable circumstance is attributed to the expensive character of the method, and it is said that before the necessary apparatuses that have been well and successfully tested at Chiswick can be obtained, co-operation is needed among the cultivators. A listlessness, combined with a distaste to co-operation, is thus permitted to stand in the way of an admitted help to the industry. Some day, perhaps, we may see these evaporators in the hands of cultivators and owners, who will lease them to the fruit-farmers, similarly to the practice common in the case of threshing-machines. In any case, it is essential that the system be made part of the routine work upon fruit farms, and if this was done, the further planting of Plums and Pears could be conscientiously recommended. At present, in a season of plenty, the former fruit scarcely pays for the gathering.

In turning to the competitive classes in the schedule, we find that division 4, embracing ten classes, has been allotted to counties or groups of counties. Thus, the two competitions in the "Special District County" classes are for six dishes of Apples, distinct, four of cooking varieties, and two dessert; and for six dishes of distinct Pears. These exhibits are to be entered in one of the ten classes, according to the counties from whence the fruit will come. In one of the classes Scots growers will compete amongst themselves; in another, cultivators in the Emerald Isle may exhibit. The six northern counties are grouped with the Isle of Man; Worcestershire and Hereford are placed with the more favourable Welsh counties, such as Glamorgan, Carmarthen, and Pembroke; whilst another class provides for growers in the rest of the Welsh counties. Class 70 is open to growers in Lincoln, Northampton, Warwick, Leicester, Notts, Derby, Staffs, Shropshire, and Cheshire. The fruit growers in the counties of Essex, Suffolk, Norfolk, Cambridge, Hunts, and Rutland, will compete with each other, as will also those in Wilts, Gloucester, Oxford, Bucks, Berks, Beds, Herts, and Middlesex. The importance of Kent as a fruit producing county is expressed by the wording of the class 66, "Open only to Kent growers;" and in the next class are grouped together some adjoining counties, including Surrey, Sussex, Hants, Dorset, Somerset, Devon, and Cornwall. The reason for this grouping of counties is obvious. The opportunities for northern fruit growers, or even cultivators much further south, to win prizes in competition with growers from more favoured localities are next to none.

What chance, for instance, is there of a Staffordshire, Shropshire, or Yorkshire cultivator winning a 1st prize from growers who live in the vicinity of Maidstone? These latter exhibitors themselves are so fully aware of the great advantages they possess over others in less favoured parts, that we are sure they will be amongst the first to admit the justice of the new arrangement. It is important of course to encourage exhibits of fruit from every county, and to this end, it is obvious that growers in each must be given the opportunity to compete for the prizes under something like equal conditions.

The importance of packing in the case of fruits sent to market, is acknowledged by the provision of additional classes for market-growers, there being now twenty devoted to the illustration of the best methods of packing various kinds of fruits.

There has been conspicuous disinclination among nurserymen, as a whole, to enter the competitive classes open solely to them. This would be natural if a firm might show a collection of fruits in the hope of an award equal to

be awarded a prize of greater value than a Silver Medal, however large or meritorious the fruits may be. Gold, or even Silver-gilt Medals, may only be won by boldly entering the ranks of those who compete. But, in this case again, it would seem more fair if the nurserymen were also to be grouped together in district competitions.

Altogether there is evidence that very considerable time and care have been bestowed upon the compilation of this schedule, and we

always white from the three lower segments down the tube, and purple from the two upper segments, the throat covered with small spots, and the white segments edged with violet. The flowers are very numerous, and thus make a very attractive display, though only about seven-eighths of an inch long. The leaves are round, slightly heart-shaped, and of dark green colour, with purplish veins, reminding one of *Nægelia zebrina* in miniature; they are borne on very slender stems, which proceed from a tiny tuber. Flowers are produced over a long season, but are most numerous and effective in spring. It is a native of Brazil, and was introduced by Messrs. JAS. VEITCH & SONS about thirty-seven years ago. Though very charming in any stove, it is scarcely now a commercial plant, but finds refuge at Kew and Cambridge, the accompanying illustration having been prepared in the latter garden. Its culture is not difficult, but requires some care. If treated much as a *Gloxinia* it is perfectly happy, but several should be grown in a pan. It is increased by separating and striking the shoots. R. I. Lynch, Cambridge Botanic Gardens.

SIR WILLIAM AND SIR JOSEPH HOOKER.—In acknowledging the presentation by the Linnean Society of a special medal as previously reported by us, Sir JOSEPH HOOKER thus gracefully alluded to the part that his father had taken in launching him in his career and supporting him in it:—"It remains, Sir, to thank you cordially for coupling my father's name with my own in this award; but for which, indeed, I could not have accepted it without a protest. I inherited from him my love of knowledge for its own sake, but this would have availed me little were it not for the guiding hand of one who had himself attained scientific eminence; who, by example, precept and encouragement, kept me to the paths which I should follow; launched me in the fields of exploration and research, liberally aided me during his lifetime, and paved for me the way to the position he so long held at Kew with so great credit to himself, and benefit especially to our Indian and Colonial possessions."

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Fruit and Floral Committee will be held on Tuesday next, June 14, in the Drill Hall, James Street, Westminster. Tuesday's meeting will be the first at which the Sherwood Silver Cup, value £10 10s., will be competed for. This award is for the encouragement of effective arrangements of annual and biennial flowering plants. A conspicuous exhibit in connection with the meeting will be a large group of Malmaison Carnations from Dover House gardens. These will probably occupy 400 square feet. A lecture on "Hybrid Orchids" will be given by Mr. JAMES O'BRIEN, V.M.H., at 3 o'clock.

THE LOSS OF PLANTS AT THE TEMPLE SHOW.—To our great humiliation and regret, we are unable to report any intelligence concerning the missing plants. We trust the Society will take some public means of expressing the sympathy that is universally felt for Mr. JULES HYE, and that it will take steps to prevent any such disaster in future. A letter from a correspondent in another column shows one way in which such disasters may be obviated.

THE NATIONAL HORTICULTURAL SOCIETY OF FRANCE arranged a ball which took place on the 21st ult., and which is described as a great success. The profits are to be devoted to the fund for the relief of necessitous gardeners. The "assistance" worked hard, for we are told they did not separate till 5 in the morning.

LINNEAN SOCIETY.—On the occasion of the evening meeting to be held on Thursday, June 16, at 8 P.M., the following papers will be read:—I. "Observations on the Seasonal Variations of Elevation in a Branch of Horse-Chestnut Tree," by Mr. MILLER CHRISTY, F.L.S.; II. "On Pantopoda, Collected by Mr. W. S. BRUCE in the Neighbourhood of Franz-Josef-Land," by Mr. G. H. CARPENTER, B.Sc.; III. "Morphological Relationships of the Actiniaria and Madreporaria," by Mr. J. E. DUERDEN, A.R.C., Sc.; IV. "On Some Fossil Lepidoptera," by Dr. C. J. FORSYTH MAJOR, C.M.Z.S.

FIG. 137.—*SINNINGIA CONCINNA*.

the 1st prize in the competitive classes without incurring the risk of being placed 2nd to any other firm. Two years ago when commenting upon the exhibition which had just been held, we said that the unwillingness of nurserymen to enter the competitive classes might involve, at a future time, the making of arrangements that would offer to the trade greater inducements to do so.

The Council continue to try to make their trade competitive classes more popular by withholding the highest prizes from non-competitive exhibits. These latter will not

trust that fruit-growers from every county in England, from Wales, Scotland and Ireland, will strive to make the forthcoming show the most representative yet held at the Palace.

SINNINGIA CONCINNA (*STENOCASTRA CONCINNA*).—The accompanying illustration (fig. 137), from the pencil of Mr. F. W. BURBIDGE, M.A., V.M.H., represents one of the most charming of Gesnerads. It is an immediate relative of the garden *Gloxinia*, but contrasts strongly with it in being many times smaller, and also in its much quieter coloration. In this it does not vary, being

A WINTER HORTICULTURAL EXHIBITION IN BERLIN IN 1900.—As we learn from German journals, it is the intention of the Prussian Horticultural Society to hold a winter horticultural exhibition early in 1900; and the general secretary of the society has already approached the Minister of Education on the project. It is likely to meet with the heartiest support in Berlin.

ROSE SHOW FIXTURES IN 1898.—Mr. ED. MAWLEY, Rosebank, Berkhamsted, obliges us with the following fixtures, since the last list published in these columns on May 14:—June 29 (Wednesday), Brookham; July 5 (Tuesday), Diss; July 13 (Wednesday), Bedford; July 14 (Thursday), Reading.

MALFORMED CATTLEYA.—Messrs. HUGH LOW & Co., of Bush Hill Nursery, Enfield, send us flowers of *Cattleya Mendeli*, in which the perianth is reduced to two sepals and two petals without a lip. The occurrence is not rare in Orchids; but what is unusual is, that the column retains its curved direction. Commonly in such flowers it is straight.

RELATIVE MERIT OF BULBS.—The following is the result of the *plébiscite* lately instituted by the Dutch Bulb Society. Coloured plates of the premiated varieties will be given in the *Florilegium Haarlemense*.

WORK AT THE ESSEX TECHNICAL LABORATORIES.—The *Journal of the Essex Technical Laboratories* for August-December, 1897, contains:—Notes and Reports on Experiments, 1896-7; Study for Horticultural Students (illustrated), a tuberous-rooted Begonia; Report of the Horticultural Students'

Society; Report and Experiments in connection with the Salt-water Flood, November, 1897; Dairy Bacteriology, Result of Examinations of the County School of Horticulture and Study of Fungi. From the general notes we glean a very good idea of the type of work undertaken at the laboratories. The subjects dealt with include agriculture in various branches, and considerable attention also is devoted to the scientific side of gardening. Thus, there is an autumn school of horticulture which “met during the month of November. It was mainly attended by young gardeners who held horticultural scholarships granted by the East Suffolk Technical Instruction Committee. Considerable attention was devoted to propagation of plants and to fruit culture.” The Horticultural Students' Society (in connection with the Essex County School of Horticulture), is an association “to promote home-study, and to encourage out-of-door observations of matters and things bearing upon horticulture. Each member undertakes to prepare, once a year, an original paper upon some gardening subject, such paper to be the result of actual study and experience on the part of the writer. These essays are circulated amongst the members, and notes and criticisms invited.” A sample paper printed in this journal is on “The culture of the tuberous Begonia for bedding purposes,” by Mr. FRANK ISTD, who stood first in the (Essex) list of candidates at the Royal Horticultural Society examination in 1896. The advantages of the Students' Society are, of course, the incentive to continue work begun in the schools, and the keeping up of intercourse between present and past students all over the country. It is interesting to note in what special branches of horticulture instruction is most sought. “A number of lecture courses on horticultural subjects has been given during the session, and good attendances have in most cases been secured. A pleasing feature of the work is the interest found in old centres when revisited. Fruit-culture is still the principal subject in demand throughout the county, and pruning invariably proves an acceptable part of the instruction. The subject that perhaps stands second in popularity is the propagation of plants, and considering its importance, it is no wonder that it claims the attention of so many lovers of plants and owners of gardens.”

FLORA OF TIBET.—Various collections have been received at Kew, according to the *Kew Bulletin*, the largest made by H. E. HOBSON, Esq., stationed on the eastern frontier of Sikkim, and botanically in the humid Himalayan district. It may be expected that numerous novelties will be found in this collection.

COFFEA STENOPHYLLA.—The *Kew Bulletin* prints a letter from Mr. HART, of Trinidad, in which the merits of this species, a native of Sierra Leone are pointed out. The berries are dark purple, not red, and the flavour of the prepared seed is excellent. Steps have been taken to introduce it into other West Indian islands.

DUTCH HORTICULTURAL AND BOTANICAL SOCIETY.—On the occasion of the meetings of March 9, April 20, and May 11, 1898, of the Floral Committee of this Society, First-class Certificates were awarded to Messrs. V. Schertzer & Sons of Haarlem, for *Primula acaulis coerulea* (March 9); to the Botanical Garden of Utrecht for *Cineraria Lynchi* (May 11); to Mr. Baron van Boetzelaer of Maartensdijk, for *Eulophiella Elisabethæ* (May 11); and to Mr. A. D. den Older of Leiden, for *Plantago lanceolata* fol. varieg. (May 11). A Certificate of Merit was granted to Mr. Baron van Boetzelaer for *Stanropsis (Vanda) gigantea* (April 20).

CARDIFF AND COUNTY HORTICULTURAL.—The annual exhibition of this Society will be held in the Sophia Gardens, Cardiff, on July 20 and 21, being a date nearly three weeks earlier than usual. A Veitch Memorial Medal will accompany the 1st prize in the gardeners' class for miscellaneous plants. In a similar class in the open division, encouraging prizes are offered, and for stove and greenhouse specimen plants, Roses, &c.

WHAT IS EXPECTED OF A GARDENER.—The duties of a “single-handed” gardener are of multifarious enough, but the following list of expected requirements lately received by one of our correspondents in reply to his advertisement for situation says much for the hopeful disposition the would-be employer. First of all the candidate for the desirable (?) situation must—

“Please give following Particulars:

1. Name and address of references.
2. Length of character.
3. Cause of leaving last two situations.
4. Did you or your employer give notice?
5. When disengaged.
6. How long out of situation?
7. What wages have you been receiving?
8. What position have you held in last two situations?
9. Age, height, married or single, and what family?
10. Have you any knowledge of bee-keeping?
11. Are you strong, healthy, and an abstainer?
12. Have you been accustomed to use a scythe?
13. Can you have a good character for qualifications and good temper?
14. Please give an outline of your career, and the work you have been accustomed to do since (sic) the last twelve years.”

Next follow the advertiser's requirements, and mention of the work and its remuneration:—

“I require a strong, healthy, active, quick, willing and obliging man, who thoroughly understands the routine of a gentleman's small place; methodical, systematic, and orderly in his habits, punctual, and an abstainer.

Must thoroughly understand the cultivation of fruit, vegetables, and flowers. The duties I should require outside garden-work are—carrying coals, cleaning boots (no knives), cleaning windows outside, and making himself useful when necessity requires.”

My place is small, about $\frac{1}{2}$ to 1 acre in all, small conservatory and greenhouse, and a few frames.

We are three in family. You would have no assistance. We take an interest in our garden, and work it ourselves sometimes.

The wages I give to a thoroughly experienced single-handed gardener, who comes with a good character, are from £55 to £65 a year (payable monthly, calendar month, not four weekly) with a calendar month's notice on either side from any date, and at the end of the first year's service a rise of £3. There is no cottage, and you would have to live off the premises, finding your own lodgings. Your working hours would be:

From March 15 to Nov. 1 from 6 A.M. to 6 P.M.
 „ Nov. 1 „ Feb. 15 „ 7 A.M. „ 5.30 P.M.
 „ Feb. 15 „ March 15 „ 7 A.M. „ 6 P.M.

with one hour for dinner, half-an-hour for breakfast, and a quarter-of-an-hour for tea, which the gardener brought with him. On Sundays your work would be the usual necessities only: boots, coals, watering, &c., and if on week-days it is necessary to water the garden after 6 o'clock on account of the heat, I would require you to do so; and in winter you would have to return at 8 or 8.30 P.M. to attend to the conservatory and greenhouse fires.

Cottages can be obtained here for about £10 a year, and furnished rooms from 2s. 6d. to 4s.”

Put briefly, we see that the advertiser, in spite of his or her indifferent grammar, expects to obtain the services, for twelve or more hours a day, with extra work in summer and on winter evenings, of a man of good character, experienced in various branches of gardening, and in certain indoor occupations. The munificent wage offered is £5 8s. 4d. twelve times a year, with no extra privileges, and the necessity of providing board and lodging for himself and possible family.

OPEN SPACES IN LONDON.—Our readers will be interested to learn that the Metropolitan Public Garden Association have completed the laying out of the recreation grounds at East Street, S.E., and in Charles Square, N.; and these are now open to the public. The grounds in York Street and Kipling Street, S.E., are approaching completion, and will be soon be ready for the public. The West Ham Corporation have agreed to undertake the maintenance of a disused churchyard at Plaistow, E., which this Association had offered to turn into a public garden. The Association hope to be able soon to lay out the Paragon, S.E., and a neglected square in Dalston.

FLOWERS IN SEASON.—Mr. C. G. VAN TUBERGHEM, of Haarlem, sends us flowers of *Tulipa Sprengeri*, a late-flowering species, with glabrous peduncles, bright orange-red self-coloured flowers, without any central blotch; outer perianth-segments broadly lanceolate, narrower than the ovate-acuminate petals.

The filaments are red and glabrous, the anthers erect, yellow, stigmas sessile. It is not in the Kew list dated 1895. *Ranunculus myssamis* (?) is also sent by Mr. VAN TUBERGHEM. The name is not in the New hand-list of perennials, nor in the *Index Kewensis*, hence probably it is of recent introduction. It attains a height of 2 feet, with stems covered with coarse, appressed hairs, deeply, palmately-lobed leaves, and pale yellow flowers in loose terminal cymes. Each flower is about 3 cent. across, with reflexed, hairy sepals, often semi-double, and a cylindric receptacle. With these came a collection of Irises of great beauty and variety, but as the tickets became detached, it is best not to specify them.

THE SILVA OF NORTH AMERICA.—The eleventh volume of Professor SARGENT'S monumental work has just been published. It is devoted wholly to the genus *Pinus*, and is therefore of unusual interest. We shall refer to it at an early opportunity.

PROTECTION OF COMMONS, ETC.—The recently-issued report of the Kent and Surrey Committee of the Commons Protection Society is of much interest to all who are in any way concerned with the breezy uplands and Broom-gemmed commons, of footpaths and general right-of-way in country districts. Much has already been done in the years that have passed since this valuable society was called into being, and much still remains to be done by all lovers of rural beauty and right doing. How this is to be accomplished in the easiest, cheapest, and most thorough manner may be learnt from those pages. Rural "Councils" have much in their power, but in the multitude of "councillors" there is not always wisdom. The reason why is shown in this report, which we have only room here to recommend to the reader.

METROPOLITAN CONGESTED SPACES.—Complaint has been made in the public press in relation to the shutting out of the children from the enjoyment of the fresh greensward in some of the smaller open spaces under the control of the County Council, the youngsters having very literally to take a back seat in order that their elders may have their innings at lawn-tennis, croquet, &c. Of course, those who pay have a right to play; but so have the little folks, for whose benefit, principally, the grass has been laid down in so many nooks and corners, in disused burial-grounds, &c. There is little doubt of the ability of the County Council to cope with the difficulty once their attention is drawn to the subject. One more cause of what we have termed congestion is the over-planting of limited areas with hardy shrubs and laying-out of flower-beds, not always in keeping with the space at command. As we have said, it is not so much a garden as a place for recreation that is lacking amid densely crowded populations. *Verb sap.*

SIGNOR ROVELLI.—The *Revue Horticole* announces the death of M. ACHILLE ROVELLI of Pallanza at the age of 53. In his youth he was with ANDRÉ LEROY at Angers, then in Paris, after which he travelled in America, China, Japan, India, &c. The nursery at Pallanza is noted for the rare and interesting trees it contains, as well as for Camellias, which take the place of our Rhododendron.

STOCK-TAKING FOR MAY.—Whosoever would read aright the Board of Trade Returns for the month of May, must previously have studied the "Corn Averages" week by week. This will have prepared him for the fact that the increase in the value of articles of food, duty free, imported during the past month amounts to £2,188,676—the price, not of increased quantity, but of increased value, due almost entirely to the operation of a "ring" in Chicago, engineered, as it is termed, by a person who has netted as his share of the profits some five millions of dollars, and which has been made up, not from the pockets of the well-to-do, but from the thin purses of the masses, who, we are informed are week by week paying as the enhanced value of bread what is equivalent to a week's rent—where there is a family to feed. The only other increases of moment are for metals,

£103,856, and £246,323 in raw materials for textile manufactures. The total value of the imports for May is £37,706,378, as against £36,346,348—an increase of £1,360,030—the "value" of which we have just shown. Our usual excerpt from the "summary" table is as follows:—

IMPORTS.	1897.	1898.	Difference.
Total value ...	£ 36,346,348	£ 37,706,378	+ 1,360,030
(A.) Articles of food and drink—duty free ...	12,231,457	14,420,183	+2,188,676
(B.) Articles of food and drink—dutiable	1,997,958	1,987,342	—10,616
Raw materials for textile manufactures ...	5,160,092	5,406,415	+246,323
Raw materials for sundry industries and manufactures	4,143,172	3,609,859	—533,313
(A.) Miscellaneous articles ...	1,072,164	1,008,643	—63,521
(B.) Parcel Post ..	71,511	110,127	+38,616

We believe that, as a set-off to this somewhat sombre aspect of affairs, the home-trade is in a satisfactory condition, not bounded by realised dividends, a number of new companies set on foot, but by the returns from the Labour Bureau of the Board of Trade. The imports for the five months of the present year are valued at £196,987,003, as against £189,031,470 in 1897—an increase in value of £7,955,533. The record of decrease in these months is represented by £31,155 for Tobacco; chemicals, &c., £557,318; and £1,429,700 in raw materials for textile manufactures. The sum of £8,196,300 stands as the increase in the value of articles of food and drink, duty free! As to the fruit, roots, and vegetables imported during the month of May, the following figures are very suggestive:—

IMPORTS.	1897.	1898.	Difference.
Fruits, raw:—			
Apples ... bush.	123,928	97,400	—26,528
Cherries ... "	56,278	10,385	—45,893
Plums ... "	3,500	91	—3,409
Pears ... "	502	496	—6
Grapes ... "	3,843	3,228	—615
Unenumerated ... "	89,463	88,573	—890
Onions ... "	463,939	352,399	—111,540
Potatos ... cwt.	385,640	1,055,256	+669,616
Vegetables, raw, unenumerated ... value	£158,244	£130,513	—£27,731

From this it will be seen that the only plus value is found under Potatos. Possibly, our farming friends may be finding their profit in other than cereal crops. Turning now to—

EXPORTS

we find a gloomy picture—only machinery and mill-work showing an increase (£142,841). The value for May is £17,891,354, as against £19,322,146 in May last year; or a decrease of £1,430,792. The largest decrease is to be found in yarns and textile fabrics which have fallen off by £907,984; raw materials fell off by £224,784; metals, and articles manufactured therefrom (except machinery), declined by £221,648; chemicals, &c., went down by £75,548; next above the parcel post item is the falling off by £19,235 in articles of food and drink. The five months' exports amount to £93,094,483, against £98,320,455 for the same period in 1897—a decrease of £5,225,972. Of course, "wars and rumours of wars" have much to do with all this; there is no set-off against the large bill we have to settle with the United States for food-stuffs.

PUBLICATIONS RECEIVED.—*The Californian Vegetables in Garden and Field*, by E. J. Wickson, A.M. (Gay & Bird, 22, Bedford Street, Strand).—*Handbook of Practical Botany*, by E. Strassburger, edited from the German by W. Hillhouse, M.A. (Swan, Sonnenschein & Co.).—*Catalogue of the African Plants collected by Dr. Friedrich Welwitsch*, by W. P. Hiern, M.A. (Trustees of British Museum),

containing the orders from Combretaceæ to Rubiaceæ, with numerous valuable annotations.—*Dictionnaire Iconographique des Orchidées*, Cogniaux, Avenue de Spa, 51, Verviers.—*The Spread of Plant Diseases*, by Dr. Erwin Smith.—*Greenhouse Management, &c.*, by L. R. Taft (Kegan, Paul & Co.).—*Elementary Botany*, by Percy Groom, M.A. (George Bell & Sons).—*Lessons with Plants*, by L. H. Bailey (Macmillan & Co.).—*A Text-Book of Botany*, by Drs. Strasburger, F. Noll, H. Schenck, and A. F. W. Schimper, translated from the German by H. Potter, Ph.D. (Macmillan).—*Weather Lore*, by R. Inwards (Elliot Stock).

COURTLANDS, NEAR EXMOUTH.

THE seat of W. Lethbridge, Esq., is most pleasantly situated on the east bank of the estuary of the River Exe, and being on rising ground from the water's-edge, commands most beautiful and interesting views of the sea as it widens out into the English Channel, with its shipping and fishing craft, for which the parish folk of Lymptone, and adjoining districts of Topsham have long been famous.

From the mansion and grounds, the lovely estate of Powderham, the seat of the Earl of Devon, can be seen also; fine views of the Haldon Hills, and the scenery up on the south-coast, embracing Starcross, Dawlish, and Teignmouth, and the lovely lands immediately adjoining.

Some hundreds of Begonias have been planted in the flower-beds, already many measure 18 inches to 2 feet across, and have stout stems and leaves. I have found Begonias to succeed best in this district in a shady and moist situation, and a light leafy soil. If the plants be exposed too much, or the soil is heavy, the strong sunshine causes the soil to crack, and this is very prejudicial to the plants.

Passing into the houses, on a shelf, in an intermediate-house, was a wonderful lot of Gloxinias, with stout foliage lying over the sides of the pots, and flowers rising in plenty, many of them being already open. These are grown in several batches, but the smallest have equal vigour to those first started. Of Carnations there is a fine collection of good varieties, and much cutting has thinned the blooms. Double Petunias are very showy; and zonal and show Pelargoniums make a good display. *Celsia cretica*, with its spikes of yellow blossoms, was gay and attractive; and a house full of Azaleas were just passing out of flower. In the orchard-house, which has a lean-to roof, I noticed on the back-wall some capital Moor Park Apricots, which had set sufficient fruits for a good crop; Pear-trees on single rods also looked well. Mr. Foster, who has charge of these gardens, invariably succeeds in obtaining crops from this house. Plums in pots cover the space between the Pears, and carry an abundance of fruit. Among the varieties I noticed Coe's Golden Drop, Belgian Purple, Kirkes, Jeffersons, and the Greengage.

The vineries are in capital condition. One has a span-roof, the rods being planted outside, and trained up one side and partly down the other. This house contained for the greater part Black Hamburgh and Madresfield Court, and the appearance of the wood, foliage, and fruit was in all respects satisfactory. Melons were in excellent condition, and the same may be said of the Cucumbers.

In one of the plant-houses I noticed some splendid plants full of flower of *Oncidium flexuosum*, so useful a plant for house decoration that it is a pity it is not

more freely grown. *Oncidium altissimum* was also gay with its lengthened spikes, but in beauty not at all to be compared with the one just mentioned. *Cattleyas*, *Laelias*, *Dendrobiums*, and *Cypripediums* of the showier species are grown in some quantity, though by no means can this be considered an Orchid place. Among the *Cypripedium*, *C. barbatum* b. *florum* or *Crossii*: the broad dorsal sepal of this old variety stands up boldly, and slightly recurves at the sides; whilst the green lines on the lower portion of the sepal gradually change into deep purple. If at any time *C. barbatum* has been naturally crossed with *C. virens* this form may be the product; it is very worthy of culture, and useful for supplying flowers for cutting. *Clerodendron Balfourianum* is grown as small bushes in 7 and 8-inch pots, and a number of plants were recently gay with their white and crimson flowers. The plants after passing out of flower are rested awhile, and in late summer again encouraged, by which means a second crop of flowers is obtained in the autumn.

I noticed a fine lot of Fig-trees in pots, and a larger tree in the border. Figs again, outside protected by glass covers, were looking well.

In the kitchen garden, the three sorts of Peas now most promising are Veitch's First and Early, Exonian, and Goldfinder. These, Mr. Foster informed me, he can always depend on. *W. Swan, Exmouth.*

FOREIGN CORRESPONDENCE.

THE FISH RIVER.

(Concluded from p. 316.)

NEXT day I made an excursion to a mountain in the opposite direction, and I was much surprised to find a number of the same (?) *Stapeliaceae*, which I had found in the perfectly different climate of Lüderitzbucht. Two to five branches arising from a very short common stem, branches club-shaped and 4 to 5 inches long, at the top 1 to 1½ inch thick, very spongy and elastic, grey, without any spines or rudimentary leaves, covered with rows of flat papillæ. For the first time I found here, in dry watercourses, a most beautiful *Papilionaceous* shrub, 2 to 3 feet high, with ternate leaves, flowers in colour very similar to those of *Polygala myrtifolia*, but larger; pods terete, 3 to 4 inches long.

The day of departure had come with the arrival of the mail, just the evening before I had heard of the Geitsi! gubib, a mountain not far from Bersaba. As I had time, and my collecting portfolios were still rather empty, I hired two new men well acquainted with the path between Keetmanshoop and Bersaba, and started next morning for that place, which is only 60 English miles from Keetmanshoop in a northern direction. Not far off there was, in the sandy plain, a chaos of dark brown boulders (of a granitic mineral), the holes between them wonderfully filled out with hundreds of red-flowering *Aloes*, such as I never had seen before. There was also a charming *Hebenstreitia*, with extremely long, white flowers; and the common *Tribulus*, with its golden-yellow flowers 2 inches in diameter, crept over the naked stones. Later on the plain was covered with bushes of an *Asclepiad*, with very slender stems, narrow linear leaves, and small greenish-yellow flowers. The Hottentots use it for thatching their huts. The pit of Chelab, where I found half-a-dozen Hottentot huts, was full to its margin with a perfectly dark clay-coloured, thick water, which I could drink only with closed eyes. Oh! if I had always on my excursions such water! but often it is mixed with impurities of all kinds, and has, especially when heated by the burning sun, a not very agreeable taste of ammonia. It was well that I did not follow the advice of my men, who recommended me not to fill the water-bags here, as we should find water in the bed of the Uibes, where we intended to sleep. As we arrived there late, we found two pits in the middle of it, but not a drop of water in either.

The next morning, descending the Uibes, we arrived on a Vley. A Vley is a very hard smooth plain of yellow clay, on which one may find sometimes weeks after rain stagnant water in the deeper pools. Generally it is quite deficient of any vegetation. Almost always I found a creeping *Malvaceae* with large leaves and thick clusters of deep blood-red flowers on it. A rather large quantity of seeds of this plant was sent to Haage & Schmidt, Erfurt. I do not know why it has received the name *Hakjesdoornvley*, as I saw not a single *Acacia detinens*

(*Hakjesdoorn*, Wait a bit), but surrounding the stagnant water only: *Acacia* sp., *Salsola*, *Celastrus*, *Zisiphus*, an *Andropogon*, a *Lycium*, a *Convolvulus* with minute flowers, a *Sida*, *Aitonia capensis*, an *Atriplex* of the section *Halimus*, a leafless *Capparid*, with *Genista*-like dark green branches, orange-coloured flowers, and bean-like fruits, which, when they open, show coral-red seeds; and a *Gomphocarpus*, common everywhere in the whole country. There was also a colony of nests of a yellow weaver bird, the nests hanging with a thin thread of grass from the end of the spiny branches of *Zisiphus* above the water. For the first time I heard the roaring of a bull-frog, which has so striking a resemblance to the lowing of cattle that I used to look around for them until I saw my men laughing, which explained to me the origin of the noise.

BERSABA.

At 10 o'clock we crossed a hill, from the top of which I saw the white mission-houses of Bersaba, to the left of the Geitsi! gubib. At noon we had to cross the Fish River, at this spot 75 yards broad, and knee-deep. On its banks I found an *Ocimum*, a yellow-flowering *Nasturtium*, a very pretty tree-climbing *Momordica* with creamy flowers and orange-red fruit, containing about ten seeds enveloped in blood-red pulp, and great quantities of *Argemone mexicana*. On the way from the Fish River to Bersaba I noticed numerous Arrow-trees, whose wood is very much valued by waggon-builders. The species belong to the *Leguminosæ*, and it is a very stately tree, with thornless thick branches, and five to six pinnate leaves. At last, at half-past nine in the evening, we arrived in Bersaba, where I presented myself to the missionary, Mr. Hegener, by whom I was received with the greatest kindness. I was shown to the schoolhouse, where he had improvised a guest's room. The next day, a Sunday, I attended the service in the church. Mr. Hegener spoke in Cape-Dutch, which a Hottentot interpreter, standing below the pulpit, translated sentence by sentence into the Nama language. This language is a very peculiar one, as it contains four sounds, difficult to be pronounced even by many Hottentots. I was told that people who are not able to pronounce them, imitate them with the fingers. It is not at all a language suitable for preaching, as the interpreter is compelled to make ludicrous motions with his head to enable him to pronounce the sounds. Mr. Hegener showed me his garden, founded forty-eight years ago by the first missionary of Bersaba, Sam. Hahn. There were a splendid Vine, Fig-trees, *Punicas*, Pumpkins, Watermelons, Melons, and a great thicket of *Arundo Donax*. This giant Grass, grown so much in Italy, is used here to make the ceilings of the rooms. Besides, it is, when young, an excellent fodder-grass for oxen, but I have never seen it planted on a large scale for this purpose. I made the acquaintance of the Captain, and found him a very clever young man, who understands German and Dutch, and who was, before his election, the schoolmaster at Bersaba. He and some others have gardens, in which they grow Fig-trees, Pumpkins, &c. Water is supplied in fair quantity by several wells, and could be augmented by boring new ones. I advised the Captain to grow Kaffir corn, as this most precious plant will bear a rather salt soil, and does not require much manuring and water, though it is very grateful if it gets both copiously. The people find themselves obliged to begin with horticulture and agriculture, as the rinderpest has showed them that cattle-farming alone cannot protect them from hunger in such difficult times.

Monday morning I started with my two men, another armed man as guide, and a blushing young buck, which I had paid for with a pound of tobacco, for the Geitsi! gubib. This is a wonderful mountain rising 700 metres above the Bersaba plain (1064 m.). It looks near, but we had to march for three hours until we reached the first stony hills, which lie around its base. On the way I found several very nice things, as a cactiform *Euphorbia*, a *Mesembryanthemum* (of the same section to which *M. nuciforme* belongs), as white as the masses of limestone between which it grows; a magnificent *Stapelia*, crossed with stripes of brown and bright green, with clusters of brown flowers, segments fringed; an *Ophioglossum*, which, if I saw it in a herbarium, I should take for our European *O. vulgatum*; four species of *Liliaceæ*, one of them apparently a *Drymis* with leaves most like the beautifully brown spotted leaves of *Phalænopsis Schilleriana*; an *Anacampseros*, and a tuber-bearing plant with flowers much resembling those of a *Lysimachia*, whose large tubers are eaten by the natives. On the abovesaid hill grew a shrubby *Acacia* with whitish cylindrical flower-spikes (like *Albizia*).

From here I recognised the true nature of the mountain. It is a perfectly circular mountain, only towards the south is there an outlet about 60 yards broad, which forms a cascade 50 yards deep. The watercourse is accompanied on both sides by very abrupt chains, nearly as high as the mountain itself, which conduct the rain-water into the plain.

Descending into the valley I found a nice Fern, probably a *Cheilanthes*. Climbing upwards in the torrent-bed we found, after ten minutes, a great natural obstacle in our way, a cascade 6 yards deep, descending to a little pond. It was not possible to get over the obstruction without some precaution. It had although an almost perpendicular, very smooth rock, a few short horizontal clefts about an inch broad. However, we had to wait for sunset, as the sun had heated the rock so that we could not touch it with the hands, still less with the naked feet. With boots it would have been impossible. Without accident we arrived before the already-mentioned grand cascade, where there was also a little lake at its foot. As it was absolutely impossible to climb it, we succeeded, by taking a roundabout way, in reaching the interior of the mountain. It is like being in the crater of a volcano, or in an enormous arena, which is 1½ kilom. long, and 1 kilom. broad, surrounded by a chain of steep mountains 300 to 500 m. high. Our first care was to find a good camping-place, and it was found in a little watercourse close by the outlet. Charcoal and quantities of oxen-bones were lying about, and the Bersaba-man told me that cattle-thieves camped here a few weeks ago.

The flora offered me, quite against my anticipation, very few novelties. There were about a thousand *Aloe dichotoma*, which covered the whole crater-plain, some of them ascending even almost as high as the ridge; *Grewia flava*, and a *Grewia* with white flowers, bordered together with the "Brack-bush"—*Stinkbush*; *Acacia detinens*, several *Acanthaceæ*, and a *Verbena*. In stony places grew a very fine *Apocynaceous* shrub, with large and long-tubed white flowers; and two shrubs of which I could not state the relationship. All the other plants were such as are common everywhere in the lower country.

Although I could not, after such experience, expect much from an ascent of the Ring-mountain ridge, I decided to execute it the next morning with two of my men. In less than one hour we were on the highest point, where Messrs. Rehbock and Watermeyer had erected an obelisk of pieces of rock. The view from here was a very extended one over an enormous plain, sprinkled with low table mountains. The Fish River and some of its branches were now full to their margin, and the former could be distinguished at a distance of more than 100 miles of its length by its green tree borders. As the borders of the Fish River are indeed as low, as they seemed to be from this height, I am convinced that they will be converted in future times into fine and profitable *Eucalyptus* forests and gardens, which might well suffice to sustain ten times the number of settlers and natives who now form the population of the whole Namaland. My botanical booty consisted of two *Cucurbitaceæ*, an *Allosorus*, and a single specimen of a *Stapelia* new to me. In the late afternoon we returned on the same track to Bersaba, with the satisfaction of having ascended a mountain which only four white men had previously ascended. Now (January 24) I am sitting still in Bersaba without seeing the possibility of getting back to Keetmanshoop, as the Fish River is, in consequence of several heavy rains, so swollen that we cannot cross it. *K. Dinter.*

EASY ROOTING OF POPLAR CUTTINGS.

When arriving from the interior at Lüderitzbucht, a post-parcel from Messrs. Haage & Schmidt, Erfurt, containing cuttings of the common pyramidal Poplar was handed over to me by the customs officials. How astonished I was to find that all the 500 cuttings were rooted along their entire length, and most of them had made even five to six shoots. Both ends of the cuttings were overgrown by a very strong callus, and as the cuttings had all the same length, several of them were grown together at both ends. The cuttings were wrapped in moist moss, and they came to hand four and a half months after being despatched from Erfurt. *K. Dinter, Salem, Damaraland.*

THE CHORIZEMAS.

THESE beautiful New Holland plants, blooming as they do throughout the winter and spring months, are certainly worthy of culture for both greenhouse and conservatory decoration. Chozizemas are well

FIG. 138.—*ACERAS BOLLEANA*: COLOUR OF FLOWERS ROSY-RED AND GREEN.

adapted for training up pillars or over a balloon-shaped trellis, and if well grown few plants are more attractive. The stock may be easily increased by seeds or cuttings, but those raised from seeds usually furnish the best results, having a tendency to grow and flower more vigorously. Seeds should be sown as soon as they have ripened in summer, in pots containing light sandy soil. If cuttings be used, select half-ripened shoots during July or August, and insert them in sand under a bell-glass. The greatest care is absolutely necessary in the preparation of the pot before the cuttings are inserted. Half fill them with carefully placed crocks, and cover these with rough fibre obtainable from peat. Over this place a layer of finely-sifted peat and sand in equal parts, and finish with well washed silver-sand. When the cuttings have been carefully dibbled in, water through a fine rose, and plunge the pots in a half spent hot-bed. Shade the cuttings from sun until they have rooted, and then pot them off into thumbs, and place them on a shelf on the north side of the greenhouse, close to the roof-glass. The compost best suited for the plants when they become large enough [for shifting into 3 and 5-inch pots, and subsequently, is one composed of two parts peat, one of leaf-soil, and one of turfy-loam, with sufficient silver-sand and crushed charcoal to keep the whole light and porous. Pass the whole through a $\frac{3}{4}$ -inch sieve before it is used.

In potting ram the soil firmly and evenly round the sides of the pot. The best place for larger plants after potting, is in a close frame or pit where they may be syringed twice a day for a time. Ventilate cautiously until the roots are pushing freely into the new soil. The stronger shoots may then be pinched, to induce a compact stocky growth.

Manure-water, if well diluted, may be given with advantage about once or twice a week. Red-spider and thrips are sometimes troublesome, but these can be exterminated by repeated syringings with a solution of soft-soap and sulphur.

There are several varieties in cultivation, of which the following are amongst the best, *C. Henchmanni*, *C. angustifolium*, *C. cordatum*, *C. spectabile*, and *C. Earle*. The last-named is a compact-growing species, and blooms most profusely from April to June. *H. T. M., Stoneleigh.*

ACERAS BOLLEANA,

*Siehe, nov. sp.**

THIS fine terrestrial Orchid, which attains a height of about half a metre, Mr. Siehe found in the forests of *Juniperus excelsa* in the north of the Porta sibirica, 3100 m. above sea-level. Professor Haussknecht thought at first that it was *Aceras affinis*, but a comparative examination proved it quite distinct. The plant is very fragrant, the flowers green and rosy-red. No spots occur on the labellum. There exists also a very rare variety with quite green flowers; the leaves resemble those of *A. hircina*. There exists also a very rare variety, the flowers of which are quite green. It grows near Gullek, about 1100 m. above sea-level, in a loamy soil. The illustration (fig. 138) shows a flower-spike of half the natural size. *Dr. Dammer, Gross Lichterfelde, Berlin.*

HOME CORRESPONDENCE.

THE EFFECTS OF GRAFTING UPON THE GRAPE-VINE.—At different times I have been much interested in this question, of the effects of the stock on the graft, and *vice versa*; and probably one of my latest references to the subject in these pages was that of a case which came under the notice of the late Peter Grieve, of Culford, and myself. This case resulted in something remarkably like the Duke of Buccleuch Grape, through the grafting of the Golden Hamburgh on to the common Hamburgh. The Duke shoot in this case sprung from a point below that of

* *Aceras Bolleana*, n. sp., Siehe and Hausskn. [Half natural size. Height about 27½ inches. Flowers rose-coloured and green; rarely entirely green. A variety is forthcoming. Leaves as in *A. hircina*. From Gullek (?), at an elevation of 3009 feet, in loamy soil.]

the union, and was different from that of any other Grape in the vine. Years before I had visited the late Mr. Fleming at Trentham, and noted various modifications of colour, size, and quality that seemed the direct result of the crossings, or, in other words, of the effects of the scions of the stocks. Through the mistake of a generous friend, who supplied me with my first Vines for planting several houses, this matter was early forced on my attention. Hardly one of the Vines proved true to name, so nearly the whole of them had to be grafted, budded, or inarched. So soon as the first two bunches determined their character, the whites proved to be White Tokay, Tulliano, Calabrian, Raisin, and the Muscat of Alexandria—the latter in considerable numbers. The blacks were Black Prince, Gros Guillaume, Gros Colman, and West St. Peters. This Muscat proved the best stock, for Buckland Sweetwater, Foster's Seedling, Cannon Hall Muscat producing enormous berries without cracking, and also very fine finished Black Alicante, Black Hamburg of several varieties, and Buckland Sweetwater did well on Black Prince, Gros Colman, and Gros Guillaume. But while there was no change of colour resulting from the free crossing of the Vines, there were striking modifications of size, quality, and finish in most of the Grapes. The effects on growth, too, on such strong-growing Vines as Gros Guillaume, when furnished with a few fruiting Hamburg leads, was most striking; though, on the other hand, no attempt was made by the Hamburg bunches to imitate those of the stock in size or length. But these and other or greater changes have long been familiar to cultivators. This short cut to the hastening of fertility to-day lies in the direction of the right selection of scion and stock for this purpose. For several years we have found fertile stocks for old scions without number; in other words, we have been practising this doctrine of the dominating effects of fibrous and surfacing rooting stocks on the scion. It may be well at times to consider the reverse side of this question, viz., the effects this soon exercises on the stock. No fruit-grower denies either, as proofs are continually cropping up in regard to the mutual influence of stock on scion, and *vice versa*, but the causes still remain obscure. Hence your lucid explanation in your closing sentence, on p. 348, will be cordially welcomed, that "the changes are much more intelligible now that it is known that protoplasm passes from cell to cell instead of each cell being a closed sac." This may be accepted as the true reason of the dominating effects of fibrous and surface-rooting stocks in hastening and increasing the fertility of a plant, results which are more or less permanent. But so far as our present knowledge shows, the effects which the scion exerts on the stocks are erratic and uncertain, whereas if we accept in all its fulness this theory of sacless cells, and the free intermixture, without restraint of protoplasm, the effect of the scion on the stock should surely be far more constant and potential than anything we have yet seen, and might prove quite subversive of that general unity and uniformity of form, expression, and quality found in Vines and other fruits of mixed blood. The actual results of the changes noted through grafting and budding so far, seem to point to some sacs or atoms retaining a certain individuality, which reveals itself irregularly, while, in the main, working in harmony with the centre mass of protoplasm, which is building up the plant and its fruits. But Mr. Elliott's letter suggests another, and perhaps a yet more important point, viz., how far scions may weaken health and introduce disease. The shoots forwarded to you are not only shortened but malformed. Every grower knows that the mere fact of working a shoot of Madresfield Court on a Foster's Seedling, or either on a Hamburg, should neither weaken growth nor cause malformation. The fact points to something else being amiss with the stock than its wrong name. It would be interesting to know whether the Vine inarched was suffering from the Vine-mildew, that often leads to malformation and to disease. In either case, it would not be safe to work the infected Hamburg Vine at present, but to cut it down to the roots, and graft or inarch with Madresfield Court, or any other variety later on. By such means Mr. Elliott would probably get beyond the infected germs or protoplasm. But should he find any disease in the malformed shoots, it will be better to root up and burn the Vine, and fill its place with a cane from an adjoining Vine; or the soil might be removed from the border, put on the garden or farm, and rich, turfy loam put in its place, and a strong Vine planted as soon as practicable. I may add, that I have

never seen a case of malformed Vine-growth from budding or grafting, unless where fasciated shoots have been used for scions or leads. *D. T. Fish, Pettes Row, Edinburgh.*

THE LOSS OF M. JULES HYE'S ORCHIDS from the Temple Show, as reported in this week's *Gardeners' Chronicle*, came like a thunder-clap on the horticultural world, and every Orchid-grower in the country will sincerely sympathise with him in his loss, especially those who have so recently had the pleasure of seeing his collection in Belgium. The question at once arises, who is to blame? undoubtedly, the owner, or whoever was in charge, is to blame for leaving them in the tent till that time of night. For myself, I only had a few to pack, and I was out soon after 8 o'clock; and on returning half-an-hour later found the employés of Messrs. Sander, Cypher, and others in the trade still at it by the light of lamps and candles. It struck me at the time that there was every opportunity for plants to be lost, and this brings me to the point where I think the Society is to some extent to blame. Why not close the show in reasonable time, so that the exhibitors may both pack and get their plants loaded by daylight; at this time of year, say, close the tents at 4 P.M. Those who pay for entrance after that time include some who avail themselves of the opportunity of laying their hands on anything in the shape of flowers or plants. What more likely than one of that fraternity, seeing those plants stand by themselves in the darkness, without knowing anything of their value, took them up. I have another plaint to make. The show is closed at 6 P.M. (on paper), when the tents are to be cleared of all but exhibitors, but no clearance was attempted beyond one policeman calling out "Clear out, please." All the time packing was going on, the public were crowding and pestering for Ferns and flowers round every exhibit. This is not as it should be. But in justice to the Royal Horticultural Society, it must be said that it is not the only society which does exactly the same thing. I maintain when a society has more than a one-day show they ought to close early enough on the last day to allow exhibitors to pack up by daylight. If that had been adopted in the present instance, it would have been nearly impossible for those plants to have been taken away unseen by someone. I hope the lesson thus taught will not be thrown away, and that the Royal Horticultural Society will set the example of closing at more reasonable hours, to the benefit of every exhibitor in the kingdom. *S. S.*

MICROBES IN WATER, AND THE DAMPING OFF OF CAULIFLOWERS AND STOCKS.—Your correspondent, "A. D.," in his remarks on this subject, p. 317, in this journal of the 21st ult., says "Amateur gardeners are often in trouble from this cause, and as often asking advice." Now, I know from experience professional gardeners are likewise troubled with the same affliction. I remember the question, "What causes stocks to damp off?" being asked at a horticultural mutual improvement society's meeting, held in the North of England, where most of the members were professional gardeners. The question was discussed at great length, various opinions being given. I said then, and still say, that too much water is the main cause. It is quite a common practice with many gardeners to dip all boxes or pans containing Cauliflowers and Stocks, both before and after being pricked out, believing that the mere fact of their being dipped will prevent all danger from damping. Now, I maintain that as much, or even more, harm may be done by dipping than otherwise. How often do we see a box or pan held in the tank until the water shows up through the surface of the soil. Where this happens, it were just as well to water overhead at once, as by allowing the water to reach the surface from the bottom, the soil absorbs more water than it would do had the watering been done through a rose. Allow the water to reach the neck of the plant, and you may rest assured damping will follow. Not for a moment would I recommend watering either Cauliflowers or Stocks overhead, but just mention this to show how much harm may be done by over-dipping, and if microbes are present in the water, the more water absorbed by the soil the more microbes will the plants have to contend with. Dipping in water much colder than the temperature of the soil in the boxes is another help to damping. Here we learn another lesson. The colder the water the more microbes. The following plan I tried this spring, and found very effectual with both Cauliflowers and Stocks indoors; i.e., to surface each box with about a quarter of an inch of pure sand, sowing

the seed on this, and covering lightly with more sand, the boxes being watered a few hours before with warm water from the boiler. When pricking-out, I again surfaced the boxes with sand a little deeper, and was careful, when watering, never to immerse the boxes more than half their depth in the water, the temperature of which had been raised a degree or two higher than that of the house—ainery ranging from 55° to 60°—by adding warm water from the boiler. To this mainly I ascribe my success, having had very few losses from damping, although the plants, during the seedling stage, were kept in the moist atmosphere of a newly-started vinery. *W. J. Pife.*

FORCED PEAS FOR MARKET SALE.—The remarkable samples of early marrow Peas shown by Messrs. Sutton & Sons at the Temple, very naturally set me wondering how far it might be possible to produce such fine samples in sufficient quantity and at comparatively moderate cost for market sale, to render such practice profitable. To judge of the very best varieties for this purpose it would be needful to see them growing under glass in precisely similar conditions, and even then it is needful to go further and ascertain the weight of pods a number of rows of a given length would relatively produce. Prior to the recent show, the examples of forced Peas hitherto seen have been usually produced on plants grown in pots and boxes. The Temple samples were from sowings made in long rows under glass, and furnished with sticks as in ordinary outdoor culture. The houses in which they were grown are long broad spans very light and airy, and whilst the dwarf varieties are sown nearest the sides the taller ones come more into the centre. It was good policy on the part of the firm to exhibit only four varieties, and these were all of the same average height, i.e., from 3 to 4 feet. But then in the four baskets of each variety shown, there were fully two bushels, thus making eight bushels in all, really in the respect of bulk a wonderful quantity for house production. The finest sample was Early Giant, bearing a grand pod, something like to that of Duke of Albany. The Peas were of capital cooking size, the pods containing nine and ten green Peas, thus showing that the shelled product would be excellent. *A. D.* [Messrs. Sutton & Sons, in a communication received from them since the Great Show, inform us that on a previous occasion by the command of the Queen some of their marrowfat Peas were sent to Windsor for her Majesty's inspection and served at the royal table. This year two baskets of Early Giant were taken from the Show to Marlborough House by command of the Prince of Wales for use at the Derby dinner given by his Royal Highness. *Ed.*]

THE HARDINESS OF RESTIO SUBVERTICILLATUS.—In the *Gardeners' Chronicle* of July 6, 1895, in a note on the propagation of this plant by cuttings from the older stems, I pointed out the greenhouse as the most suitable place for its cultivation. In several gardens where it is to be found, it is grown in a temperate-house, or, indeed, in the stove. That this kind of treatment is not required, may be demonstrated, and it only tends to weaken the plume-like stems, and the plant gradually becomes smaller. From a batch of cuttings struck in the manner described in the above-mentioned note, one was placed in the cool end of the succulent-house, where it made good progress, and threw up stems about 3 feet in length. During the summer of last year this plant, at the suggestion of Professor Balfour, was placed outside in a wide recess between the houses, where it was sheltered from all sides except the south by the houses running at right angles from the corridor. Here it has stood the winter well, with only the protection afforded by its own dense plume-like growths (which, indeed, must be admitted is considerable), and a thin sheet of tiffany-shading thrown over it during frosty nights. The winter of 1897 was, of course, an exceptionally mild one, and the test of its hardiness was not a very severe one, only about 18° being registered here on the grass as lowest fall in temperature. During January two stout Asparagus-like growths made their appearance, but did not thrive. Just now there are about thirty young shoots to be seen, all when compared with the larger older specimen in a greenhouse of a very sturdy nature, and bid fair to develop in stems of extra strength. This may perhaps be accounted for, to a certain extent, by the vigour possessed by a young plant. In the warmer parts of the south and west of England, Ireland, and Scotland, where such plants as Tree-Ferns and Cordylines succeed, this plant might be expected to thrive; if, indeed, it does

not prove perfectly hardy anywhere in these islands. R. L. Harrow, Royal Botanic Garden, Edinburgh.

GRISELINIA LITTORALIS.—I do not think the flowering of this New Zealand shrub is common, although it does so here every year. I enclose a sprig cut from a bush 15 feet high, and 16 feet through. It would cover more ground, but we have to prune one side of it, owing to a specimen Holly which we have under the name of *Ilex Cunninghamii*. This *Ilex* is a pretty plant, over 14 feet high by 16 feet through, but I am doubtful if the name is correct, so enclose a small sprig of it also. I may say the *Griselinia* is quite hardy here, although it likes a sheltered place, and is an excellent shrub for the seaside. D. S. Melville, Pottalock Gardens, N.B. [The *Ilex* sent is *I. dipyrrena*, of which the name *I. Cunninghamii* is a synonym. Ed.]

GARDENERS' SELF-HELP.—Your correspondent signing himself "Subscriber," in his reply, p. 298, to "C. C." advises the latter to join the "Oddfellows, or some other benefit society," and, curiously enough, for one who writes as having a knowledge of gardeners and their doings, omits any allusion to our own particular benefit society, viz. the United Horticultural Benefit and Provident Society. May I suggest that this is the Society *par excellence* for gardeners, as in many ways it stands ahead of all other such societies; and it should be considered a privilege by all gardeners to be eligible for membership. I will only mention one of its great advantages, which is, that there is no fixed sum payable at death, or when the member has reached a certain age; but all the subscriptions he has paid, less the very reasonable sums required for management and sick-pay, stand in his name for withdrawal when he reaches 70 years of age, or, in the event of death, by the person whom he may have nominated to receive it, and it bears interest in the meanwhile. These moneys frequently amount to a considerable sum, sufficient to greatly alleviate the distress to which most gardeners' families are liable at such times, instead of the small fixed sum paid by other societies at death. J. C. Tallack.

THINNING KITCHEN GARDEN AND OTHER CROPS.—Few operations connected with the management of a garden are of more importance than the timely and judicious thinning of all crops; and not only is this necessary on the score of appearance, but for full success. Vegetable crops are not the only ones that suffer by the non-performance of this operation at the proper time, but hardy fruits on wall-trees and bushes, whose products will grow finer than if left to crowd each other. The work of thinning is more expeditiously performed when it is begun in good time. Small seeds of vegetables are frequently sown very thickly, hence the need of early thinning—that is, as soon as the plants are large enough to be handled. Turnips, Carrots, Parsnips, and Parsley suffer greatly if not promptly thinned, and in the moist weather prevailing in the spring the plants are easily pulled up. Generally speaking, Onions for the main crop should be left somewhat thickly in the lines, being further thinned when pulling for every-day use. I am an advocate for leaving Onions fairly thick in the lines, the bulbs in ordinary seasons growing quite large enough for all ordinary kitchen purposes. If larger bulbs are wanted, let them be grown on a piece of ground prepared, and set apart a few lines. The seeds of Beans and Peas are generally sown no thicker than they are expected to grow and bring to perfection, hence it is not necessary to thin in this case. When Lettuces of sorts are grown in lines where the seed is sown, and this is admittedly the better way with midsummer crops, it is necessary to see to the early thinning of the plants, as once drawn up and weak, are always drawn. The same holds good of Endive, Celery, Celeriac, Asparagus, and of the Brassicas, more especially when the seeds are sown in drills instead of broadcasted. The crop that is soonest spoiled by lack of thinning is Radishes. In fact, it is the best policy to use only new seed, and sow thinly, as any drawing of the plants results in failure to form good bulbs, or, at least shapely, tender-eating ones; and the production of much leafage. It is a well-known fact, but one not always acted upon, that Parsley well thinned—say to 10 inches or more, will endure the rigours of winter with fewer losses of leafage or of plants than crowded, weakly plants. Plants standing at this distance apart form good masses of leaves that curl outwards and downwards, rendering it an easy matter to tuck some Oak or Chestnut-leaves

closely around each plant for winter protection, and further render the plants proof against frost and wind, the latter doing more harm sometimes than the former, by twisting and breaking the leaf-stalks. H. T. M.

THE SEASON IN N.-E. ABERDEENSHIRE.—This has been a very trying spring. All vegetable crops have made little progress, owing to the cold wet weather. Since the end of April we have had very little sunshine, and a deal of rain. There have also been frequent showers of hail, and cold biting winds from the N. and N.-E. There is no heat in the ground to encourage young and tender crops to grow. The fruit crop may prove to be an average one. John Brown, Delgatty Castle Gardens, Turfiff, Aberdeenshire.

THE TENTS AT THE TEMPLE SHOW.—Is the efficient ventilation of a marquee-tent impossible, or even very difficult? If not, it is to be hoped that those who are responsible for the arrangements of the Temple Flower Show will do their best to remedy what was a great drawback to the show this year—the stifling atmosphere of the tents. No doubt many of the visitors were strong enough in nerve and stomach to continue in the tents without inconvenience or distress; but the many exceptions, especially ladies, whose nervous system and circulation are not vigorous, felt much discomfort, and after being pushed through one tent, without a chance of escape, were very glad to take refuge in the open air till they left the show. This complaint, it is true, is common when flower-shows are crowded. The tents at Shrewsbury last August were equally stifling, but the weather was much hotter. The most comfortable large flower-shows I have ever seen were at the Crystal Palace and the Westminster Aquarium. [?] C. Wolley Dod, Edge Hall, Malpas.

MARKET GARDENING.

MARKET GARDENERS', NURSERYMEN'S, AND FARMERS' ASSOCIATION.

A THIRD list of subscribers to the fund for defraying the expenses of an appeal to the House of Lords on the question of Rating of glass-houses, has reached us. The Association has determined to proceed with the appeal, although the response to the application for funds has not been so general as the importance of the matter demands. Assistance is solicited from the numerous growers who have not yet contributed. George Monro, Hon. Treasurer, 32, King Street, Covent Garden, London, W.C.

SOCIETIES.

ISLE OF WIGHT.

JUNE 4.—The monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Newport on Saturday last. Dr. J. Groves, B.A., J.P., presided over a good attendance.

Mr. S. HEATON (Hon. Sec.) read a paper on "Bees," and Mr. F. MIDLANE exhibited and explained various bee-keeping appliances. These appliances received recognition in the form of a Certificate, as did a patent watering-can staged by Mr. J. E. WATTS, Sunbury Gardens, Middlesex.

Votes of thanks were accorded to Messrs. T. COLLISTER (Bembridge), and J. WILLIAMS (Gatcombe), for collections of *Aquilegias* (Veitch's New Hybrids).

THE SCOTTISH HORTICULTURAL.

JUNE 7.—The usual monthly meeting of members was held last night, Mr. M. TODD, the president, in the chair. Mr. ALEXANDER JOHNSTONE then read a paper on the Fuchsia and its cultivation, which was followed by considerable discussion.

Among the exhibits shown at this meeting was a beautiful white corollaed Fuchsia named Annie Laing, said to be a most valuable one for market purposes. A fine spike of *Saxifraga pyramidalis*, measured 2½ feet long and over a foot wide across the base. This is one of many grown in Edinburgh by Mr. BRVSON. A fine bunch of a new yellow Pansy was shown by Mr. COMFORT. It is of a soft deep lemon colour with a velvety chestnut-brown centre. Three dozen bunches of excellent Asparagus were shown by Mr. SMALE of Blackford Park, Edinburgh. The grass measured

8 inches in length, each head being green and edible all the way from base to summit; this bunch of three dozen heads was 4½ inches in diameter, and weighed 1½ pounds. Thus every 108 medium-sized heads of Asparagus of this length would yield 472 pounds of nutritious food. This exhibit was the more interesting as Mr. SMALE had been reading the recent statements in the *Gardeners' Chronicle* respecting the merits of foreign and home-grown Asparagus, and staged his bunch as a fair sample of that grown in Edinburgh.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

JUNE 8.—We have again to record the anniversary dinner of this gardeners' charity, which took place in the Whitehall Rooms at the Hôtel Métropole, London, on Wednesday evening last, under the presidency of Sir OSWALD MOSLEY, Bart., in the unavoidable absence of His Grace the Duke of Portland.

Preparations were made for an attendance of 150 guests, but the number attending fell somewhat short of the estimate. Among those present were the Very Rev. the Dean of Rochester, and Messrs. W. E. Gumbleton, J. B. Bennet-Poë, H. Veitch, J. P. Veitch, A. W. Sutton, O. Thomas, N. N. Sherwood, Dickson of Chester, H. B. May, P. Crowley, W. Goldring, M. Sutton, G. Norman, H. Williams, G. Monro, Assbee, and others. A greater number of gardeners were present than it has been our good fortune to remark on previous occasions.

The customary loyal toasts having been proposed by the chairman, and heartily responded to, he proposed the toast of the evening, "Continued success to the Gardeners' Royal Benevolent Institution," first requesting the secretary to read a letter from the Duke of Portland, in which it was stated that his doctor had forbidden him all exertions for the present, and he was glad his place was to be filled by so able a gentleman as Sir Oswald Mosley, and that he would be most happy to come forward on some future occasion. The chairman said he was no gardener, but still he had made an early acquaintance with one vegetable production, the Birch. Moreover, his grandfather was fond of botanical pursuits, and President, he believed, of the Horticultural Society of London. He thought every one should endeavour to instil in the minds of gardeners the benefits of self-help, and the necessity of rallying to the support of gardeners' charities.

Mr. H. Veitch, in responding to the toast, alluded to the regret felt by the Gardeners' Royal Benevolent Institution at the unavoidable absence of the Duke of Portland, but he was sure that Sir Oswald Mosley had the sympathies of the meeting. The institution was making good progress. Mr. Veitch further alluded to the additions made to the number of pensioners since the occasion of the last anniversary dinner, and to those who had passed away, the last of these in point of time being a gardener's widow, who, together with her husband, had received in money a sum of £408 in return for a small annual subscription. The pensions were increasing at the rate of £100 a year, and at the present time amounted to £3000 a year.

He thought that the success of the Institution was due in part to its benefits becoming better known generally. He spoke of the Victorian Era Fund of £5000, £4000 of which had been obtained and invested, the interest of which was intended to afford assistance to unsuccessful candidates, the recipients receiving 15s. for each year they had subscribed. The treasurer read several letters of thanks from those who had been afforded donations. The Victorian Era Fund would still be kept open, a sum of £800 being required to complete the amount. The affiliated societies were most encouragingly alluded to, especially those of Reading, Wolverhampton, and Worcester.

The very Reverend the Dean of Rochester made an excellent speech on the toast "Gardening," carrying with him the feelings of those present, enlivening it by humorous anecdotes, allusions to the varied charms of old-fashioned gardens, with their surprises and characteristic features; to old-fashioned flowers, and of course to the Rose, the Dean's especial favourite. He thinks that our gardens are too few, possess too little beauty, and are too much alike.

The list of subscriptions included the following sums:—Duke of Portland, £52 10s.; Sir Oswald Mosley, Bart., £52 10s., and £10 annual subscription; Jeremiah Colman, £52 10s.; J. Veitch & Sons, £20; Messrs. Rothschild, £105; Hurst & Son, £20; N. Sherwood and Miss Sherwood, £5 5s. each; the Dean of Rochester, £5; Dickson & Robinson, £35; per G. Monro, £131, and an annual subscription of £18 18s.; A. Sutton, £50; M. Sutton, £25; Baron Schroder, £20; A. Wilson, £20; Lord Wantage, £10 10s.; W. H. Lees, £21; Mrs. Courage, £25; F. W. Bond, £14 14s.; per G. Norman, £15 5s.; L. Salomon, £10 10s.; W. Thompson, £21; per G. Maycock, £10; W. J. Nutting, £8 8s.; G. J. Brackenridge, £7 7s.; per G. A. Dickson, £50-£100; the Worcester Auxiliary sent £70; W. Crump, £20; W. Jinks, £18 10s.; W. J. Baker for the Thames Bank Iron Co., £18 13s.; Fisher, Son & Sibray, £10 10s.; C. Turner, £5 5s.; G. H. Richards, £10 10s.; and W. Corry, £5 5s. The total subscriptions amounted to £2,300. The Victorian Era fund received additions from N. Sherwood, £50; A. W. Sutton, £50; H. J. Veitch, £10; and L. Sutton, £50.

Obituary.

JOHN GIBSON.—Floriculture has lost one of its devotees in the person of Mr. John Gibson, Erleigh Road, Reading, who died very suddenly on the 7th inst. In a small garden at the back of his residence he cultivated Auriculas, having select collections of the best named show and alpine varieties; and he was also a raiser of seedling Auriculas, making careful and systematic crosses, and keeping an accurate record of the same. He was more fortunate in the raising of good new selfs than of edged varieties. He was especially successful with Seedling Alpines, and when looking over his collection in April last, I noticed he had a few among the white-centred section of decided promise. He was a great admirer of Daffodils, and cultivated a select collection of these. He also grew Tea Roses, and his small garden, which occupied a gentle slope towards the south, during the summer was rich in fragrant blossoms.

A florist of the old school, he always deplored what he regarded as the lowering of the standard of quality in Auriculas, contending that size rather than refinement was admired in the present day. Few men enjoyed greater pleasure among their favourite flowers than did John Gibson. Occupying a position of trust in the railway clearing-house, he was constantly travelling about the country, and always joyfully turned to his garden when at liberty to be in it. He was a member of the National Auricula, Carnation, and Chrysanthemum Societies, and was constant in his attendance at the meetings of the Royal Horticultural Society in the Drill Hall. *R. D.*

ENQUIRY.

"He that questioneth much shall learn much."—BACON.

CARBOLIC ACID IN SEWAGE.—I have, writes "G. H.," a well close to the garden, into which run the drainings from a laundry and stables; and the drains are washed down regularly with carbolic acid. Would this, if applied to fruit trees in general do any harm? I fear the acid would injure the plants, although hundreds of gallons of water go down the drains daily. Would any of our correspondents having experience kindly inform "G. H." if any harm to the trees is likely to occur.

BOOKS: *Libra.* Botany for Beginners, though out of print, may be picked up at the second-hand book-stalls; and Darwin's *Elements of Botany*, published by the Cambridge University Press in 1895, will afford you good elementary information on systematic and structural botany.

GARDEN LABOUR: *W. J. P.* So far as we can tell without seeing the garden, eight men and a boy would be the required number; that is, reckoning two men in the pleasure-grounds and flower-garden, three men in the kitchen-garden, one man on the walks for weeding, &c., and two men and the boy in the glass-houses; the master-gardener superintending the whole garden without a foreman under him. The men should be active, and capable of doing a fair day's work.

GRAPES: *W. Button.* The berries are affected with the minute fungus, *Gloeosporium laticolor*. There is no known cure. You had better cut out all spotted berries, and burn them forthwith. Your methods of culture seem good, and they are not the occasion of the appearance of the fungus; neither would a totally different course of treatment bring it on the Grapes. *Gloeosporium laticolor* affects other plants as well as Vines, and the spores are carried about by the wind. Syringing with water, in which sulphate of potassium at the rate of ½-oz. to 1 gallon of the former is dissolved, might do good in so far as it would destroy any spores alighting on the berries. After a certain time the risk of infestation would disappear for the year, as in the case of other fungus visitations of a like

nature.—*J. A. N.* A bad case of scalding, due to lack of ventilation at the right time.

MILDEW [?] ON TOMATO: *C. E. W.* Apply the Bordeaux Mixture or sulphate of potassium at the rate of ½-oz. to one gallon of water. If it really be mildew, perhaps flowers-of-sulphur would arrest its spreading over the plants, but it is likely to be some other species of fungus.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*A. D. W.* *Cratogeomys coccinea* var. *indentata*, so far as can be judged from the specimen sent. It should have scarlet fruit in corymbs.—*T. R., Germany.* The *Cattleya* is an ordinary form of the *Cattleya Mossiae aurea* class.—*K. S. L.* *Valeriana officinalis*.—*H. Musto.* *Euryclis sylvestris*.—*A. V. P.* *Dendrobium moschatum*.—*C. A. B.* 1, *Veronica gentianoides*; 2, *Spiraea filipendula*; 3, *Pteris aquilina*; 4, *Polystichum angulare proliferum*; 5, *Stapelia* species, send flower; 6, *Pachyphyton bracteatum*; 7, *Mesembryanthemum* species. The white on the portion of Apple-tree sent is American blight. Dress next winter with paraffin emulsion.—*J. E. P.* *Amelanchier vulgaris*.—*J. Claydon.* *Tacsonia exoniensis* ×. Seeds of this plant might be obtained of Messrs. R. Veitch & Son, 54, High Street, Exeter, the introducers; or of M. E. Benary, Erfurt, or MM. Vilmorin, Andrieux & Cie., Quai de la Mégisserie, Paris, but we greatly doubt if the plant reproduces itself true from seed, it being a cross.—*J. W. R.* *Ceanothus thyrsiflorus*.—*Cerasus.* *Prunus Padus*.

NARCISSUS GOING BLIND: *J. C. L.* The cause of the blooms never opening or "going blind," is still to be discovered. Some say it is due to moisture within the envelope, and may be averted by slitting the latter; others ascribe it to improper culture, the need of often replanting, &c. In our own case we have grown the Poet's Narcissus in the same soil for many years with the result that the flowers were always blind; this year, however, the same plants bloomed beautifully.

PEACHES DROPPING: *H. G.* The cause of the fruit dropping is luxuriant growth and insufficient ripening of the same. A dressing of lime would only make matters worse in this instance, as it renders a more abundant supply of nitrogen available for the trees. As soon as the fruits are the size of Walnuts, afford half a pound per square yard of border of the following mixture:—Three-sixths superphosphate, one-sixth steamed bone-flour, two-sixths muriate of potash, applying this mixture just before affording water to the border, and lightly fork it in. Do not make use of any other manure this year. Afford abundance of air during the day, and a small amount at night. At the end of the month of October let the soil be carefully removed from the roots, and lift the trees; see that the border has a good firm bottom at 2½ feet below the surface, and sloping to the front lights. Lay drain-pipes 8 feet apart across the border connecting with a main-drain outside, around and over these place a layer of stones or brickbats 6 inches deep, and over these lay thin sods, grassy side downwards, and then replant the trees. If the old soil is sweet and in good condition, some of it may be used again, with the addition of one-sixth of the whole of turfy loam, and one-sixth charred earth. Keep the roots spread out evenly, and do not let them dip towards the bottom. *W. H. Divers.*

PHENIX-LEAVES DISEASED: *Newton.* The fungus on Phoenix-leaves sent is *Graphiola phoenixis*, an ally of the grain-smuts. The disease attacks Palms of this and allied genera; it has been observed outdoors on the Mediterranean coast, and indoors in this and other countries. The spots bear the reproductive organs of the fungus, and from them spores are rapidly given off. The plant sent is probably too far gone for remedy, and will only be a source of danger to other Palms in your house. We should get rid of it. If the fungus were recognised in the earlier stages, a good strong mildew spray, such as Bordeaux Mixture (see the *Gardeners' Chronicle*, August 21, 1897) might be used. The fungus probably came with the plant, or was introduced with other Palms. For a figure of *Pestalozzia phoenixis* attacking Palms in a similar way, and *P. macrocarpa* found on Ferns and Palms in South Europe, see *Gardeners' Chronicle*, vol. xxii., 1884, p. 429.

SPOTTED LEAVES OF ODONTOGLOSSUMS AND CATTLEYAS: *J. D., Tooting*; and *T. P., York.* These

spots on Orchid leaves are, unfortunately, too common. We have examined several cases, but do not care to ascribe them to the action of a fungus, nor to recommend any remedy used against these enemies. The spotting might well be the result of some error in treatment, especially in watering.

TOMATO-HOUSE: *F. Y., Bradford.* The larger house would be better if sunk 2½ to 3 feet in the ground. It would accommodate a greater number of plants, and be more economical in maintaining the necessary degree of warmth, and the fluctuations of temperature would be less than in a house having smaller cubical contents.

TOMATOS: *J. Claydon.* The plants are attacked by *Peronospora infestans*. Apply the Bordeaux Mixture, or sulphate of potassium, ½-oz. to a gallon of water.—*Constant Reader.* The plant is attacked by the so-called "Sleepy Disease," the result of infestation by a fungus, the *Diplocladium* and *Fusarium* stages of which were figured in the *Gardeners' Chronicle* at p. 709, vol. xvii., 1895. Root out and destroy by burning.

VINES: *F.* Your Vines are, we should suppose, in good order at the root, for the leaves sent are of much substance, and of good size for Muscat of Alexandria; but you have maintained too much humidity in the house, and not paid sufficient attention to the ventilation at the right moment, hence their yellow appearance. There was no fungus, and no insects were found on the leaves. We cannot, as a rule, reply to questions through the post; it would be too onerous.

VINE-LEAVES BROWNED: *Amateur.* Although you have certainly afforded an excessive quantity of water to the soil of the border, the true cause of the disfigurement is lack of air when the sun is shining strongly on the house early in the morning. You should begin at this season to afford air at 6 to 7 A.M., and increase it by degrees as the temperature rises, endeavouring to keep it about 80° till the sun-heat declines, when the ventilation should be reduced in like manner till closing time, say 3 P.M., when a good damping down should be given.

VINES WITHOUT ARTIFICIAL HEAT: *F. Y., Bradford.* By erecting large lean-to vineries, facing due south, and having fixed roofs glazed with large panes, and substantial walls at the back, with shading on the north side to maintain warmth in the wall, such Grapes as Buckland Sweetwater, the best of the Chasselas, Foster's Seedling, and Black Hamburg, would finish off satisfactorily; but it would be prudent not to hurry the starting greatly, for fear of a check from low temperature in May and early June, although such a risk would be eliminated by having a bed of fermenting tree-leaves and manure in each vinery until June was out.

WHITE BLOTCHES ON PLUM LEAVES: *W. J. C.* These blotches are caused by the case-making larvæ of a very small moth, of the genus *Coleophora*, probably *C. fuscadinella*. Spraying with petroleum emulsion would be likely to stop the damage. We do not think any serious harm to the trees is likely to result beyond the unsightliness, and the larvæ are now nearly full-grown. *R. McL.*

DIED.—Many readers will learn with regret of the death of Mr. STEPHEN SPOONER, of the Hounslow Nurseries, which took place at his residence at Hounslow on the 3rd inst., at the age of seventy-five.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED, and that it continues to increase weekly.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, and ALL CLASSES OF GARDENERS AND GARDEN-LOVERS at home, that it has a specially large FOREIGN AND COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Markets and Weather, see p. viii.)

THE

Gardeners' Chronicle.

SATURDAY, JUNE 18, 1898.

ROSE EXHIBITIONS.

AS the season for these approaches, we find the old topics are pretty sure to come to the front: the unsatisfactory way in which the Roses are placed on the exhibition-table, the formal character of the boxes containing the blooms, the want of any artistic arrangement, are points upon which we are sure to hear a good deal, and we have been asked during the last two or three years—"Why cannot you show your Roses as Mr. George Mount of Canterbury does, with stems 18 inches or 2 feet long, so that they can be seen in all their beauty without the formality and monotony that surround them when they are exhibited in the ordinary method?" It may be as well to refer to this before proceeding further: the carrying out of such an idea for general exhibition is simply impossible; the plants from which those magnificent blooms are cut are all grown under glass, consequently no weather-stain can ever reach them; there can be no outer petals damaged by rain, or scorched by excessive sunlight. But it may be said, "Do not they exhibit this way in America?" Possibly; but then their Roses are all grown under glass, subject to the same conditions, preserved from the same misadventures, and cultivated without any regard to expense, for prices are obtained there for blooms which would be likely to make the mouths of our purveyors in Covent Garden water at the idea. Moreover, it would be difficult to obtain in many of our varieties cultivated in the open such long clear stems as those to which I have alluded. But even supposing that this difficulty could be obviated, I think it may well be asked whether exhibiting in such a manner would serve the ends for which our Rose-shows exist; we want to see and examine what are our best flowers. We do not allow any extraneous aid to be given to the blooms except the wire for stiffening the stems; all the flowers are by the present method brought clearly within the eye of the spectator, while the judges, when so minded, can examine each bloom without any difficulty—and hence, notwithstanding the outcry, I do not think we could improve upon the present system. I have seen Maidenhair used extensively, but somehow or other one always felt there was an incongruity between the graceful and delicate fronds of the Maidenhair Fern and the solid blooms of the Rose. It must be remembered, too, that no arrangement of baskets which can supersede the old style of boxes has ever commended itself to those who are most deeply interested in it, namely, the exhibitors. By

some it has been suggested that the back rows might be shown with long stems, while the front ones should be shown in the old way. I do not think that this would be a success. I have noticed, for instance, at the Temple Show groups of magnificent plants shown in pots, with a row of boxes of blooms placed in front, and, to my mind, both have been spoiled. The group should be left to display their unique beauty, while the stands of blooms should be placed elsewhere.

There are some few things which young exhibitors will do well to remember; indeed, I have seen them neglected by those who are "old stagers." One of these is the want of taste which is sometimes shown in the arrangement of the flowers; thus, I have more than once seen in a stand some half-dozen of red Roses of various shades placed in a row, and several light-coloured Roses grouped together in the same stand, and I have often longed to say to the exhibitor, "Why don't you mix them?" Both colours would gain by the contrast, and the stand would look infinitely better. There are some people who seem to have no eye for such matters, while with others it is a matter of intuition. We may not altogether like the present system, but there is no reason why we should make it worse by such violations of good taste. There is another matter in which young exhibitors, and indeed some old ones, are apt to make a blunder, namely, staging flowers which are a little too advanced: they go into their gardens the evening before or on the morning of the show, and they see a magnificent bloom of, say, Horace Vernet or Louis van Houtte, and they think that will make a grand feature in my stand, and so it would if it could be judged then and there; but it has to be placed in a box, carried some distance, and then perhaps exposed in a tent for half-an-hour before the judges come round to it, and when the exhibitor comes up to his stand, he is disgusted to find its beauty gone. It is, of course, very tantalising to have to put upon one side a bloom of such excellence, but he who wishes to win must make up his mind to act with Spartan rigour. Again, young exhibitors must be careful to take with them a box of what are called "spares," that is of blooms which are not much more than forward buds, but which the journey in the circumstances surrounding them will develop, so that they will be just at the state for putting in the boxes. I have known a stand of twelve which had been carefully arranged when the exhibitor left home of which not one met the judges' eye; they all had to be changed—in fact, this is one of the great difficulties of Rose exhibiting. You may arrange your stand of Chrysanthemums, Dahlias, or Carnations, and have only to draw them out when you come to the place of exhibition, and they will require nothing further to be done to them; but no such pleasant ways are the portion of the Rose-exhibitor.

There are also some Roses which have an unpleasant way of showing the centre of the flower prematurely. These varieties are very doubtful ones to put in the stand, and when the Roses are what are called thin, that is, without a sufficient number of rows of petals, this is very often the case. Young exhibitors also make a mistake in imagining that the Roses must be cut on the morning of the exhibition; the fact is, that though they may look fresh and beautiful, the dew that has fallen on them during the night is rather injurious than beneficial. If the blooms are cut in the evening before sundown, and the stands are placed in

an out-building where the ground around them can be plentifully soaked with water, the flowers will be a great deal fresher. I recollect once a stand having been brought from Exeter to Norwich, and taking off the 1st prize, one great merit of the stand being the freshness of the blooms; but then the exhibitor, Mr. R. G. Baker, knew how to grow his Roses, as well as to exhibit them.

There is another point on which the rosarians are much interested when they attend our great exhibitions, namely, the noticing what new claimants to their favour may be brought forward. As usual, the French growers bring out a host of so-called new varieties, but so few of any real value have been added to our lists of late years, that it is very unlikely that we should receive much from them this year. There is indeed a Rose, White Maman Cochet, which, if it should be really white, will be a most valuable addition to our white Tea Roses; but the great bulk of the novelties for which we are looking come from home-growers. As usual, Messrs. Dickson & Sons, of Newtownards, head the list, and I have just received from them two coloured plates and descriptions of their forthcoming novelties: the premier place amongst these is, I think, to be assigned to Killarney, this is a Hybrid Tea, and promises to be a real acquisition, the colour is flesh, shaded white, suffused with pale pink, the buds are said to be pointed, and would evidently imply that it is partly of Tea origin; like the Teas, too, it is said to bloom profusely through the entire season. In Ard's Rover we have a Rose of a very different character, it is a dark climbing Hybrid Perpetual, the colour is deep crimson, shaded maroon; it is not likely to be an exhibition Rose, but it will be a most valuable one for garden decoration, as we have nothing like it in colour in the vigorous garden varieties—it is said to be most luxuriant in habit. In Beryl we have a Rose which is likely to be in great favour where decorative flowers are looked for, it is a Tea Rose of branching, robust habit; the colour is rich golden yellow, and showing the long pointed bud characteristic of the Tea Rose, and wherever flowers are required for decorative purposes this variety is likely to be much thought of. In Daisy we have a Rose which its raisers believe will be serviceable for exhibition purposes: it is of moderate habit, but the flowers are of good size and perfectly formed; the colour is rosy pink, suffused with silvery pink. Another Tea Rose, suitable either for garden decoration or exhibition purposes, is Meta: as described by its raisers, it is a very remarkable colour, for it is said to be the colour of crushed strawberry, suffused with saffron, the base of the petals coppery-yellow, different coloured flowers being produced on the same plant; from its colour and robust character it is likely to prove a most valuable flower for decorative purposes. Rosarians will also be likely to look for Ulster, which obtained a Gold Medal last year at the metropolitan exhibition of the National Rose Society, and promised to be a good successor of Mrs. Sharman Crawford and Helen Keller.

Paul & Son's Royal Scarlet is a Rose that those who are anxious for decorative flowers will do well to look for: it has already been exhibited and greatly admired, and will be a fitting companion to their Carmine Pillar, and Single White; it is a true H.P., is of bushy habit, and the flowers are the nearest approach to scarlet we have amongst Roses—it is admirably suited for bedding, and the flowers are produced in rapid succession. Cooling's Purity

is another Rose which will gladden the hearts of those who are on the look-out for garden-flowers: it is a pure white early-flowering double Rose; it is a Hybrid Bourbon of medium size, perfect in shape, semi-climbing habit, and very free-blooming. I saw it at the National Rose Society exhibition at Portsmouth, and was struck by its decorative character. Another Rose from the same firm, called after that genial Rose-grower, Mr. R. B. Cater, comes with a high character as an exhibition Rose, the raisers call it magenta-carminé; it is a large full flower with stiff petals, and growers will do well to look for it at the Bath show of the National Rose Society.

It will thus be seen that the forthcoming exhibitions promise not to be devoid of novelty, and it is clear that those who are on the look-out for garden Roses will not be disappointed; we know not what surprises may be in store for us, but according to all appearances the present season is likely to be a gratifying one to lovers of the Rose. *Wild Rose.*

ORCHID NOTES AND GLEANINGS.

PLEUROTHALLIS.

THE species of this genus are in general not very attractive to the cultivator, "who is apt in vulgar phrase to wish the botanist joy of the five hundred species. Very few indeed would gain an award of merit at the Orchid Committee, though many would deserve that which we take to be a higher commendation, at least when judiciously given, a Botanical Certificate. *P. muscoidea* has leaves less than 1 centimetre in length; *P. colossus* has a stem 1 m. 70 in height! *Pleurothallis Rozei*, just figured by M. Cogniaux in the *Dictionnaire Iconographique*, is a species that would find favour anywhere.

"DICTIONNAIRE ICONOGRAPHIQUE."

The following are the plants figured in the last number of the *Dictionnaire Iconographique* by M. Cogniaux:—

CATLEYA LABIATA, Treveran's variety. *Cattleya*, pl. 3 B.
CATLEYA O'BRIENIANA, × *Cattleya* *hyb.*, t. 8. A presumed hybrid between *C. dolosa* and *C. Loddigesii*.

CYPRIPEDIUM NIVEUM, *Rchb. f.*, in *Gardeners' Chronicle*, 1869, p. 1038. *Cypripedium*, pl. 10.

CYPRIPEDIUM HARRISIANUM VAR. *SUPERBUM*, *Rchb.*, *Gardeners' Chronicle*, 1869, p. 108. *Cyprip. hybrid.*, t. 11. The type was the first hybrid raised in the genus by Dominy, acting on the instruction of Dr. Harris. It is from *C. villosum* by *barbatum*.

CYPRIPEDIUM NIOBE, *Rolfe*, in *Gardeners' Chronicle*, 1890, viii, p. 9. Raised by Seden out of *Spicerianum*, by C. Fairieanum. *Cyprip. hybrid.*, t. 13.

DENDROBIUM HETEROCARPUM, *Wallich*. *Dendrobium*, t. 10.
EPIDENDRUM CILIARE, *Linn.* *Epidendrum*, t. 6.

MASDEVALLIA COURTAULDIANA ×, *Rchb. f.*, in *Gardeners' Chronicle*, 1889, p. 200. A cross obtained by Mr. Cookson between *M. rosea* and *M. caudata* var. *Shuttleworthii*. *Masdevallia* *hybr.*, t. 1.

MILTONIA BINOTI ×, *Cogniaux* in *Gardeners' Chronicle*, 1897, xxii, 393. Supposed to be a natural hybrid between *M. candida* and *M. Regnelli* *purpurea*. *Miltonia* *hybr.*, t. 4.

ODONTOGLOSSUM TRIUMPHANS VAR. *LATISEPALUM*, *Cogniaux*. M. de Barri Crawshaw's fine variety shown under the name of Lionel Crawshaw on April 26, and figured in the *Gardeners' Chronicle*, April 20, 1895, p. 489. *Odontoglossum*, t. 8A.

PLEUROTHALLIS ROZEI, *Rchb. f.* A purple-flowered species. *Pleurothallis*, t. 1.

SOPHRONITIS ROSSITERIANA, *Barb. Rodr.* A new species hitherto unrepresented in European gardens or herbaria. It has lately flowered with M. Peeters, of Brussels. The flowers are pale yellow, streaked with red. *Sophronitis*, t. 2.

WARSCIEWICZELLA WALESIANA, *Rchb. f.* Flowers stellate, with a large rounded lip, striped with blue. *Warszewiczella*, t. 2.

ORCHIDS AT SUNNINGDALE PARK.

In Major Joicey's beautiful and extensive gardens, the undulating surface affords at the present date a lovely picture in which the showy Rhododendrons, Azaleas, Cratæguses, and many other flowering-shrubs form a feature. Here is to be found an excellent example of a collection of well-cultivated Orchids, in which a great number of reputedly difficult subjects are grown to perfection by his gardener, Mr. F. J. Thorne. The secret, perhaps, is revealed in Mr. Thorne's reply to a remark of the writer on the

subject: "We grow our Orchids in the growing season, and are not content to let them merely live as some are."

The display in the house at the entrance to the first range entered is of no mean kind, the whole of the staging around the house being chiefly arranged with noble and clean specimens of *Miltonia vexillaria*. Each of the hundred or so of plants has been grown up from very small imported pieces, and at the present date they are literally covered with flowers. The finest plant to-day, bore, in 1895, when growing in an 8-inch pot, thirty-nine flower-spikes, averaging seven flowers each, or about 275 flowers in all. This was figured in the *Gardeners' Chronicle* for that year. In the centre of a group arranged on the middle

was noted, together with notable examples of *Oncidium ampliatum majus*, *Sobralia macrantha*, *Cattleya Warszewiczii*, and other *Cattleyas*. Here the many specimens of *C. Dowiana aurea* grow rapidly, and Mr. Thorne has found it best to keep this plant in growth for the greater part of the year. In the third house the *Bolleas* and *Pescatoreas* grow well, and the most unpromising and leafless plants quickly become leafy and floriferous. Two large plants of *Peristeria elata* with immense bulbs, and sending up very stout flower-spikes, were noticed apart in a corner; and on the centre stage were several plants of a beautiful form of *Dendrobium moschatum* covered with flower-spikes. This plant was sent home by Mr. James Joicey from India five years ago; as were

FIG. 139.—PTERIS CRETICA VAR. SUMMERSII: HORT. MAY. (SEE P. 372.)

stage is another fine example of cultural skill, a large specimen of the yellow-flowered *Anguloa Clowesii* with nineteen flowers, and with it are the white *A. eburnea* with several flowers to each growth; *A. Ruckeri*, whose yellow-coloured flowers has chocolate-coloured spots; and *A. R. sanguinea* with dark red markings. All of these plants are finely bloomed. Overhead hangs a grand plant of *Luddemannia Lehmanni*, with three heavy racemes of curiously-formed orange and copper-coloured flowers, which number 164.

Around it were remarked many fine specimens of *Odontoglossum citrosimum*, *Cattleya citrina*, *Dendrobiums*, &c. Among other well bloomed plants in the central group were *Oncidium longipes*, *O. Wentworthianum*, a *Cymbidium Lowianum* with nine flower-spikes, *Brassia brachiata*, *Lycaste candida*, and its rose-spotted variety *L. c. Lawrenceana*.

In the next house a fine show of *Cattleya Mossiae*

also the fine form of *Rhyncostylis retusa*, and several plants of major form of *Cypripedium exul*. The *Rhyncostylis* has white and rose-purple flowers densely arranged; and the best of the *Cypripediums* was certificated by the Royal Horticultural Society's Committee as Joicey's variety. Other good plants were likewise noticed in bloom.

In the same house we remarked a specimen of *Cypripedium caudatum* having tails 31 inches in length; besides plants of *Cirrhopetalum picturatum*, a noble *Cypripedium Curtisii*, some fine *C. Lawrenceanum*, vigorous plants of *Cypripedium niveum*, *C. bellatulum*, *C. Dayanum*, and several hybrids which were raised on the place.

Numbers of ornamental foliage plants are grown in most of the Orchid-houses, and in those where the greatest feats in Orchid culture have been achieved, the Orchids are suspended all over the roof, and the staging is covered with stove plants. In one

of these houses we saw specimens of the large, white-flowered *Epidendrum bicornutum* (Diacrium) which Mr. Thorne has grown for a number of years with increasing success. This season the plants have been covered with bloom; and a few of the spikes still remain on them. In the same house as these plants is a still more difficult plant to grow, viz., *Broughtonia sanguinea*, which is in perfection. It is a species that is scarcely ever without flowers.

Of the stove plants remarked *Acalypha Sanderiana* is the most remarkable; and among the remarkable crosses attempted with Orchids is *Cattleya Walkeriana* crossed with *Diacrium bicornutum*, the parent plant bearing a large seed-vessel. Another plant-stove contained some plants of *Dendrobium formosum giganteum*, very vigorous, and one of them now in bloom has been cultivated on the place for longer than seven years.

In the cool Orchid-houses we noticed that *Odontoglossum crispum* of a splendid type made a fine show; and there were *O. Halli*, *O. Pescatorei*, *O. polyanthum*, and other species, the prettiest of them

satisfactory to learn that some of the new varieties tested prove to be more or less resistant to the disease.

TRINIDAD BOTANIC GARDENS.

The *Bulletin* for April is now before us, and among the more important of its contents is the report of a lecture given by Mr. Hart on the subject of "Minor Industries." Minor industries may be defined as "side or subsidiary crops," in contrast with the important and essential ones, and undertaken perhaps from an experimental point of view to see if they would prove valuable in times of need or as efficient substitutes for established plantations. The lecturer pleads for different treatment in respect of these, and suggests that industries be no longer treated as "minor" when likely to assume a more important position, and that, since much is expected from the results of tentative cultural growths, these be regarded (by outsiders also) in the right spirit and with due allowance made for circumstances.

The colonial planter, in trying experiments, has to cope with prejudices and customs long established,

grafted from trees of the best kinds imported from India and from Martinique, and, owing to this statement, a gentleman residing a short distance from the Gardens sent to Martinique for a supply, totally ignorant that he could get an equally good quality within a quarter-mile of his home."

Other contents of the *Bulletin* are papers upon Fermentation, Parasitism in Scrophularinæ, notes on *Ustilago Maydis*, on Oranges, on Cacao, and on the Agricultural Exhibition lately and very successfully held.

METHODS OF PLANT PROPAGATION.

(Concluded from p. 356.)

CORMS AND TUBERS.—There are plants that form corms that are useful to ornament our stoves and greenhouses, so a few words about increasing stock of these may not be out of place. The Cyclamen, which, within the last decade, has advanced from an insignificant thin, strappy-petalled flower to a bold, substantial, and most attractive one; it has reached this by judicious selection from seed, and this method is undoubtedly the very best, as by sowing at the proper period, corms carrying at least a score of flowers may be had in less than twelve months—yet there are fortunate catches from seed, and when one has raised a very good thing, it is natural to wish to propagate it, as seed, however carefully saved, cannot be relied upon to reproduce a variety in its integrity. Division of the corm therefore is the only way open, and this is done thus: when the plant is in full vigour, while the corm is yet attached to the surface of the soil by its roots, divide it into segments, from the crown downward, taking care that every piece carries one or more leaves and some roots. Leave all to grow till the flowering period is over, and then lift the divided corm and complete the separation, potting up the pieces in sandy soil, just beneath the surface, and shading for a time. When the young stock looks established, give a gentle stimulant in the form of cow-manure or sheep-droppings in water, and a new corm will soon form at the base of the leaves above the segment of the old one. Keep these growing in a cool pit all through the summer, shading in the middle of the day, and looking out for slugs and wood-lice, and the young Cyclamens will reach the full flowering strength by the next season. The Gloxinia may be similarly handled, though as I have indicated in a former paper, it may be increased by leaf-cuttings. The Gesnera, and all its numerous allies, as Tydas, Eucodias, &c., may be increased by the division of the fleshy roots, when after a period of rest they again show signs of growing. Divide the corm into as many pieces as there are buds or eyes, and then cover them with dry sand to absorb the released sap, potting up in a day or two, but not watering till the young growth appears above the surface of the soil, and then only sparingly.

It may be here noted that the best results as regards winter bloom are secured by using young plants, and not trusting to old ones, as I fear is often done. I remember once seeing a young batch of *Gesnera cinnabarina* in flower about Christmas, with grand spikes of brilliant scarlet flowers, and foliage to the pot, these had been obtained as above directed.

Other Gesneraceous plants, as the *Plectopomas*, *Chirita*, and the lovely, but little known, *Agalmystaminea*, are easily increased by root-cuttings, taken when growth is first excited in the early spring; while the *Achimenes* proper, as a rule, give us myriads of their curious catkin-like corms, which may be turned out of their pots and potted up singly, or placed five to ten in a pot, or what is better, a shallow propagating-pan, and grown on, making handsome little specimens for conservatory decoration, or for exhibition.

I have often thought *Achimenes* might be bedded out with great advantage in spots where the tuberous *Begonia* thrives, the soil being lightened by the addition of peat and sand, and the young plants put out in July, and sheltered till they have taken hold of the soil. Experience.

FIG. 140.—*ASPLENIUM MAYI*: HORT, MAY. (SEE P. 372.)

being varieties of *O. hastilabium*, a species seldom observed in collections. Among other showy plants in bloom were *Cochlidia Noezliana*, *Masdevallias*, *Epidendrum Wallisii*, *E. radicans*, *Lælia grandis*, and *L. purpurata*.

The fruit-houses and the greenhouses were in first-rate condition, the trees in the first being heavily cropped; and the vineries told of heavy crops of good produce.

In the open garden hardy perennials were in great beauty, and especially noteworthy the numerous clumps of beautiful varieties of *Iris germanica*, great favourites here. Mr. Thorne lifts numbers of roots every year, placing these in the inside Vine-borders, where they afford a welcome supply of flowers at Christmastide.

COLONIAL NOTES.

ANTIGUA.

A VERY elaborate account of the results obtained in the experimental cultivation of the Sugar-cane, drawn up by Messrs. Francis Watts and P. R. Shepherd, has been forwarded to us. The trials made include various new varieties (new, that is, so far as Antigua is concerned), and the results of the application of different manures. The canes are suffering much from Rind-fungus (*Trichosphaeria*); it is, therefore,

and to put up with advice that would be excellent if more practical. Those who do know the possibilities of soil and climate are poorly seconded in their efforts to develop them, for instance: "The Island of Trinidad would grow enough Mahogany and Cedar to supply the markets of Great Britain, and if the whole island was simply a Mahogany and Cedar forest, it would be one of the richest lands under Queen Victoria's rule; but it would be idle to think of ever growing the Camphor-tree of the East, or 'Canaigre,' and other things. Yet! who plants Cedar? Who plants Mahogany? I am sorry to say no one does. Instead of planting, our pastures are barren and destitute of trees, destitute of trees to shelter the very cattle that an estate requires. The fact that these do not thrive in such pastures is an accepted one, and yet trees are not planted."

Outside criticism, again, often injurious, is founded on utter ignorance of the circumstances. We read how: "A gentleman lately went to London from Trinidad after a residence of some twenty years, and while there goes to a broker for advice as to whether Rubber would grow in Trinidad, when, if he had come to the Gardens we could have shown him Rubber-trees 40 feet in height, and would have shown him also the quality of Rubber they produce. . . . On one special occasion a statement was made that we had no grafted Mangos on hand, when at the very time there were over 200 plants in stock,

FOREIGN CORRESPONDENCE.

TREE VIOLETS.

A NOVELTY, which to the best of my knowledge was first introduced into Germany by Mr. L. Vieweg, of Quedlinburg, and which has of late years found great favour with the public here, is the culture of Violets as small standards, especially since the introduction of the large-flowering variety Princess of Wales. During its flowering period a prettier sight can hardly be imagined than a "Violet Treelet" (Baumchen), as they are called here, of this variety, with its vigorous foliage, and large, fragrant dark-blue flowers, borne on stout and strong stems.

Their culture is very simple. The way we manage them here, where we cannot spend too much time over them, generally to the neglect of other equally-important things, is to cut away in the autumn with as many roots as possible, the longest and stoutest runners from plants which were planted in the open during spring. These are potted in 2 to 3-inch pots, neatly tied up, and when established they are finally brought through the winter in cold frames. In March or April, according to weather, they are brought out on beds, the pots being let in up to the rim. During the summer they must be repotted several times, carefully watered, and at times afforded liquid manure. All blooms must be pinched out, and the shoots shortened, in order to obtain nice bushy plants. In order to well ripen the crowns, they are not given any shading, and this ensures a good display of flowers. In October, they are placed in cold frames until required, and in general they are treated like Violets for winter-flowering. There is a ready sale for the plants at remunerative prices. H. R. W., Stuttgart.

THE PRINCIPLES AND PRACTICE OF GRAFTING.

(Continued from p. 358.)

BUDDING.—The process of "budding," adopted principally in the propagation of fruit-trees and Roses, differs from that of grafting in the fact that only the more superficial tissues are concerned, the more deeply-seated woody tissues playing no part in the process of union between the stock and the scion as far, at least, as regards the more common method of "budding" employed. Hence it is that the path of the transpiration-current [the ascending sap so called] not being interfered with in the least degree, the operation of "budding" may be safely performed in the height of summer, and usually takes place in July or August.

In the axil of every leaf on the shoot of the year is a quiescent bud, destined, if undisturbed, to develop the following year into a branch. The leaves being removed, so as to leave but the base of the leaf-stalk remaining, a tangential shallow incision is made in the stem, so as to remove a short portion of the latter bearing the bud; as a portion of the wood will thereby be carried away, this must be carefully and neatly removed with the knife, without at the same time wrenching away the internal part of the bud. Successful budding can usually only be performed with quite dormant buds. If a bud has begun to grow, it is probable that the vascular cylinder containing the woody and bast tissues of the developing bud-branch, which is continuous with that of the stem, will be already partly formed; this being the case, in the attempt to remove the woody portion from the strip containing the bud, the internal tissues of the latter will almost certainly be torn out, for the vascular cylinder being intimately connected with that of the stem, and forming the chief framework of the bud, if disturbed, must inevitably carry away with it the surrounding tissues of the bud.

In the stem of the stock, whether in the older portion at the level of the ground or on a higher part of the stem, matters not, two incisions are made, a short transverse, and a longer vertical one running down from the centre of the latter, and of the same length as the prepared scion, both incisions being deep enough to reach the wood. The tissues on either side of the

vertical cut can then be easily raised so as to admit the scion, which must exactly fit into the pocket prepared for it, and will then have its inner surface in direct contact with the wood of the stock, its outer surface being somewhat overlapped by the outer tissues of the same. The whole is then tightly bound round with bast to prevent the entrance of sunheat or moisture, leaving the dormant bud and its subtending leaf-stalk alone exposed.

In the scion, when ready prepared for insertion on the stock, the tissues will probably be entirely cortical, and these living cortical tissues would thus become directly applied to the dead woody tissue of the stock. Now, while it is presumably possible that a partial union may be effected in this region by means of the cortical cells of the scion and some of the parenchyma-cells of the wood, or even of the still living newly-formed wood-cells themselves, the chief mode of union between stock and scion will be as follows:—After the cortical tissues of scion and stock had become united in the manner described above in the case of grafting, the rudiments of a vascular cylinder for the as yet dormant bud would be formed, whose cambial or generative layer would, by means of divisions in the cortical and bast-cells, become continuous all around with the same layer in the vascular cylinder of the stock, which cambial layer would proceed to form wood towards the inner side, and bast towards the outer side of both stock and bud, continuity being thus established not only between the cortical, but also between the conducting tissues of both scion and stock. The only region where a lack of vital connection between the two would exist would be the region immediately below the vertical axis of the bud, where the living cortical tissues of the scion rest immediately on the dead woody tissues of the stock. But this fact will not interfere with the further growth and development of the bud, for this unconnected region will rapidly become insignificant in area, and swallowed up by the subsequent growth in thickness of both stock and scion.

The above views on the rationale of grafting and budding, though naturally more or less hypothetical, are yet founded on a knowledge of the minute anatomy and the laws governing the activities of the vegetable tissues concerned, as well as on an acquaintance with the practical side of the subject; so that it is hoped they may be not unworthy the attention of the readers of this Journal. W. C. Worsdell, F.L.S.

NURSERY NOTES.

MR. H. B. MAY'S FERNS.

VISITORS to horticultural exhibitions in London, have probably remarked on many occasions some choice Ferns from Mr. H. B. May's Nurseries, Dyson's Road, Upper Edmonton. We had recently the pleasure to visit the houses from whence these are brought—the factory where these Ferns are manufactured and increased. Thousands of plants there were of saleable size, ready for the packers; a still larger number of lesser-sized plants, and myriads of tiny pricked-off seedlings. Then, in the spore-raising houses, were seedlings but just showing themselves, and the first pricking-off was being effected, the operator transferring a number of these "babies" each time he used his stick, for they were yet too small to be isolated. The purpose to which all effort is directed is obvious enough; namely, to place as many Ferns upon the market as is possible with the means at command. Hence there is a continual moving-up, and in the end the gaps are made good from the "spore" or seed-house.

It is a most interesting work, and to a Rip Van Winkle we hardly know which would be the subject of most surprise, the extraordinarily large demand that now exists for exotic Ferns, or the immense supplies obtainable from such farms under glass, as Mr. May's and others. Batches of Ferns of ordinary type as they filled or half-filled a house were thus interesting just as they are beautiful, whether new or old. But novelties have a special charm, and these engaged the major part of our time and attention. Three of these were figured in our issue for April 28, and one of them, that of Polypodium (Phlebodium)

aureum var. Mayi, is one of the most valuable Ferns Mr. May has been fortunate to raise. It was fully described in our report of the Temple Show, and nothing further need be said of it, except that it is a most distinct Fern, and there is at present but one plant of it. *Adiantum Hemslayanum* and *Davallia fijiensis effusa*, also figured in the same issue, are valuable Ferns, the appearance of the first-named being quite distinct among *Adiantums*, whilst the latter is a spreading, extra vigorous variety of the pretty Fiji *Davallia*.

Of the genus *Pteris* there are two exquisite varieties in *P. cretica* *Summersii* and *P. serrulata* *gracilis* *multiceps*. The former (see fig. 139) may be likened to a glorified *P. c. Wimsetti*, and received an Award of Merit from the Royal Horticultural Society in April last. The latter (see fig. 142) is a wonderfully crested form of the slender *P. s. gracilis*, and being bright in colour, is a very choice plant. But it is four years since, in 1894, the plant was awarded a First-class Certificate. The choicest of the gold-coloured *Gymnogrammas* is the variety *G. chrysophylla grandiceps superbum* (see fig. 141), awarded a Certificate at the Fern Conference some years since, and which in points of crestedness and abundance of powder is a considerable advance upon *G. c. grandiceps*.

At Mr. May's original nursery in Dyson's Road, where the offices are located, the Fern-growing houses branch right and left from a central corridor, and these houses are almost devoted to the plants, though occasionally one may notice some *Codiaeums* and *Cordylines*. Exotic and hardy Ferns (the former apparently predominating) in endless variety of the different species, some of them of appreciable distinctness, and others whose characteristics are not so evident, except to the specialist or the cultivator; it is a nursery where houses of elegant greenery form a contrast to the abundance of floral colour with which we are familiar elsewhere. And yet it is not all green, for how highly coloured are the young fronds of many of the *Adiantums*! There is also the variegation in the *Pterises* and other species. We can hardly praise the tinted Ferns too highly, but for the variegated ones there is not the same admiration. Perhaps it is that one does not want a variegated Fern at all."

Passing the collection of *Nephrolepis*, we single out *N. plumosus*. It is suspended in baskets, and for this purpose it is admirably suited. It is a variety of *N. davallioides furcans*, and its prettily crested fronds are narrow and recurved. Among the *Pteris* may be remarked *P. c. reginae* in the way of *P. Victoriae* and *P. tremula variegata*. It is very singular that the variegated form of *P. tremula* can only be obtained through seed from *P. Victoriae*; but Mr. May assures us such is the case. There was a fine batch, too, of *Pteris argyrea marmorata argentea* with large hard fronds of extraordinary substance. The handsome *Adiantum Farleyense* grows here easily enough, but the demand for the species prevents the retention of specimen plants.

Of *Aspleniums* we may mention *A. Mayi*, a pretty Fern with dark green, shining, hard fronds, making it a good, enduring decorative subject, either in the cut state or otherwise. (See fig. 140, p. 371.)

Of *Platycteriums*, *Polypodiums*, and many other groups, we must forbear to remark in detail; but in the large collection of *Gymnogrammas* there was a superb variety of the crested silver Fern, *G. Wettenthaliana*, and another of the gold Fern, *G. Alstoni*. In each case the variety shows more powder than the type, and the pinnae recurve, displaying the under-side.

Entering a house filled with *Codiaeums*, Mr. May remarked there was little new among the varieties, though the collection includes the best forms to date. The plants were certainly numerous and well cultivated, and a number of them showed capital colour, whilst others were in active growth. Crossing the road, there are numerous other houses, where again there are Ferns, also Palms, *Gloxinias*, seedling *Cyclamens*, thousands of *Carnations*, specially compact-habited white *Marguerites*, and *Lapagerias*, of which there are about one thousand layers taken each year.

There was a fine lot of the Cordylines, and some seedlings that are expected to show good decorative qualities. In answer to a question, Mr. May gave the following as being in his opinion the most popular half-dozen varieties:—Prince Manuk Bey, Lord Wolseley, Lord Roberts, Elegantissima, Madame F. Bergmann, and terminalis. We must not omit mention of the pretty Aralias, whose elegance of habit specially fits them for the ornamentation of the dinner-table.

THE FOUNTAIN.

This is one of Mr. May's branch nurseries, and the large market and trade business done is very obvious here. It is managed by Mr. May's son, and the most striking scene it presented was that of a large houseful of Coleus, in which thousands of brilliantly-coloured plants were upon one level, and could be seen at a glance. The scene was gorgeous, and our attention was directed to a wonderfully

just those that go to make a successful business man, he has succeeded to a remarkable degree.

MESSRS. DOBBIE & Co.'s NURSERY.

To those who have no previous knowledge, a visit to a great factory is merely a source of embarrassment; but when the visitor has beforehand a modicum of information, however small, his visit is likely to be instructive, and so a casual visitor strolling into such an establishment as that of Messrs. Dobbie & Co., of Orpington, would be bewildered at the quantities of things, many of them perhaps not in bloom, and wonder at the space and labour bestowed on such things. The florist, however, would be in a totally different position, and if he did not find much to interest and more to instruct him, we should say he was not worthy of the name. The nursery which with such enterprise Messrs. Dobbie, of Rothesay,

winter were, but then it must be remembered that the past winter was an abnormally mild one. Pansies abound, one would not off-hand say that this was a particularly good place for Pansies, rather the reverse; but here they are in as great variety as profusion, yellow, blue, purple and orange, whilst, in due time, we are promised a scarlet. It is worth noting, however, that the names of the colours attributed by florists to their productions had not always the same significance that they have in ordinary cases; the blue Primrose, for instance, to our thinking is plum-coloured rather than blue. China Asters are growing in great profusion, having been lately set out. They were in early June too undeveloped for us to be able to foretell their fate, but we believe in Kentish sun and air, and it has been proved that, like many other things, they need not be made in Germany. The Giant Comet is noted as much the best of its class.

Sweet Peas, Mignonettes, African Marigolds, Candytufts, Carnations, and Dahlias (or it would not be Dobbie's) here they are, and plenty of them, but, like many other things, they are things of the future. They will look very differently a little later on.

A turn, however, brings us to a brilliant display of hardy perennials, many in full bloom. Messrs. Dobbie's object is to secure a selection of the best and most satisfactory kinds; special attention is given to relative height—1, 2, or 3 feet and upwards. This is a comfort for the unwary and inexperienced amateur with small space at his disposal.

A patch of Pyrethrums was particularly brilliant at the time of our visit, including both single and double varieties. Both colour and form were remarkable, so that we imagine that the plants we saw are the result of much intelligent selection. Melton was noted as the best of all reds. Roses are likely to do well on this soil if afforded manure, and provision is being made for their culture on an extended scale. We left the nursery with a strong desire to see it again in the autumn, a desire which says much for the interest excited by our guide, by Mr. Fyfe, to whom we tender our thanks for the courtesy he showed us and the information he afforded.

TREES AND SHRUBS.

ARBUTUS MENZIESII (A. PROCERA).

AMONG the evergreen-trees found in the temperate parts of the globe, this *Arbutus* is one of the finest. In the forests of California and British Columbia, in moist and otherwise favourable situations, it attains to heights of over 100 feet, and as a trunk between 3 and 4 feet in diameter. In its native home it is known as the Madroño. Although in this country only comparatively small specimens exist, yet, where it succeeds, it is a very handsome evergreen, and as a flowering plant, perhaps the best of the *Arbutuses*. It has the reputation of being tender, but this applies to it more especially when young; at any rate, old specimens at Kew, about 15 feet high, have not suffered during even the hardest winters. It flowers with unfailing regularity every April and May, producing its blossoms on numerous racemes. They are small, white, and almost globular, the mouth of the corolla being very contracted. The leaves are thick and firm, oblong, and about 4 inches long; the upper surface is very dark green, whilst underneath they are slightly glaucous. It was discovered by Archibald Menzies during his voyage with Vancouver a little over a century ago, and afterwards by David Douglas.

PYRUS SALICIFOLIA

was this year the first to burst into bloom. Its flowers are white, and are produced in great abundance on the short corymbs characteristic of *Pyrus*. The young foliage when expanding is covered with down almost as white as the flowers themselves. When fully open, the upper side of the leaves becomes a silvery-grey colour, and they remain so until autumn. There is a small group of wild Pears with the same type of foliage (also early flowerers), and amongst them are *P. canescens* and *P. parviflora*, but *P. salicifolia* is the most ornamental. It grows

FIG. 141.—GYMNOGRAMMA CHRYSOPHYLLA VAR. GRANDICEPS SUPERBA: HORT. MAY.
(SEE P. 372.)

bright variety, the admixture of colours being very noteworthy. Myriads of Palms, Ferns, and other marketable plants, were noticed at this establishment. But a finer appearance is made by the nursery known as

MILL FIELD,

a mile or so distant, and the other side of Silver Street Station. These houses have been built by Mr. May, but in the case of The Fountain the place was acquired. The Mill Field establishment contains a number of large vineries for the cultivation of fruit for market. Ferns are again abundant in other houses here, and various species of plants that are destined for the market. We noticed a large number of profusely-bloomed plants of Turner's Crimson Rambler Rose, in 5-inch pots, surely as small as one can expect to flower Roses in successfully. There are Roses in the open also, which, during spring, are furnished with temporary covering, and afford early bloom.

Mr. May has been in business about twenty-eight years, and being a man whose general qualities are

have established in Kent, is a long narrow strip of ground between a lofty railway embankment on one side, and the slope of a hill facing south on the other. Similarly the ground rises from the entrance to the far end of the nursery.

The situation is open, the aspect bright and sunny, the soil a stony loam overlying chalk, but varying in quality in different parts of the ground. Seed-growing for trial and for trade purposes is carried on here on a large scale, comparatively little local trade being done. Great areas of bright colour may be seen from the railway-carriage windows as the traveller speeds by. One such blaze of colour at the time of our visit, in early June, was made by a quarter of Model White Turnip. Jealous of the reputation of this particular variety, no other variety is grown near it, indeed, we saw no other Crucifer of the kind within the nursery. On the other side of the path is a piece of Beet, which had been left out all the winter, side by side with a similar piece planted with roots which had been clamped.

It was curious to see how much more forward and productive the plants that had been out all the

20 feet or so high, and is of graceful, semi-pendulous habit. The leaves, as the name implies, are long, narrow, and acutely pointed. It is a native of the Levant, and is sometimes grown under the names of *P. orientalis* and *P. elegnifolia*.

CAMELLIAS OUT-OF-DOORS.

The *Gardeners' Chronicle* on many occasions has contained references to the value of the common Camellia as a hardy evergreen, yet it may be worth while to again draw attention to the success with which they may be cultivated in sheltered positions out-of-doors. In April one of the brightest and most charming shrubs in flower at Kew was a bush of the old variety *C. Donckelaari*. It is in the *Rhododendron* dell (where it has been planted, and has flowered for many years past), and was covered with its bright scarlet-red flowers—a colour as unusual out-of-doors as it is welcome in April. But even without them the dark glossy-green of the leaves would give the plant a foremost place among striking evergreens. There are many other varieties that succeed equally well, but this is especially valuable, owing to the bright colour of the flowers, and the absence from them of any of that stiffness which is common to many Camellias. Plants that have become too large for the greenhouse, or are unshapely, may well be tried in some position outside where there is shelter from north and east. *W. J. B.*

MAGNOLIA SALICIFOLIA AND *M. STELLATA*.

Amongst a number of other bold and showy species, these two forms have recently been flowering in the nurseries of Messrs. R. Veitch & Sons, Exeter, and have been much admired by those who have had the opportunity of inspecting them. The first-named is an evergreen species, and succeeds well with ordinary greenhouse treatment. The shiny, dark-green leaves remind one at a first glance of a small-growing Camellia, and if foliage only were taken into consideration, would be passed by without any special word of appreciation. The flowers are produced on short stalks, and are fleshy, and as is so usual with the greater part of this genera they do not expand very fully, but appear somewhat egg-shaped, only partly open. The colour of the blooms is of a rich creamy-white, with rosy-purple edgings to the petals, and a slight mottling of the same colour on the inside; but the foliage and the form of flowers are not the chief recommendations, as I consider that this species should be grown for the fragrance alone. As soon as the buds burst, one of the most delicious of scents pervades the house it is possible to conceive. Some little discussion took place recently as to the exact designation we should give to the aroma, one suggesting Pine-apple, another declared it was exactly like Heather-honey, whilst the third to whom the appeal was made agreed that both were right, but he would blend them.

M. stellata is a hardy, deciduous species, that is, it does well out in Devonshire, and would, I feel sure, in many other parts of the south and west of England and Scotland, and in Ireland almost everywhere; it is a free grower and abundant bloomer, and its expanding, star-shaped, pure white flowers, with slight flesh-colour, made it a conspicuous, and very interesting object in the border. Planted near a west wall, not fastened to it in any way, but treated just as a hardy shrub some 6 feet high; it has a large number of blooms, and has not been injured in the slightest degree by the cold winds and frosty nights. This, for outside culture, should certainly be met with more often. *W. Swan, Exmouth.*

TRAMPLING ON AN ONION-BED.

No doubt a firm bed is favourable to the successful cultivation of the Onion, whether this is found on the alluvial soil of Egypt or of Spain—not having journeyed so far I cannot tell; but I can describe how at this place I secured a good firm bed with very successful results. This experience arose out of a severe drought we had during the greater part of the summer of 1893. During the early spring of

that year we liberally manured a piece of ground for our Onions, on which, in due time, they were sown: though, owing to the great drought, they came to nothing. With the knowledge that the manure, or much of its goodness, was still below ground and unexhausted, we allowed the ground to remain undug all autumn and winter, until the next spring, when sowing-time came round again; we then merely scuffled off the weeds, gave the surface a slight pricking over with a fork, and on this confessedly rather slovenly preparation we again sowed our Onion-seed, which matured during the season of 1894 into the up-to-date way of expressing it, "a record crop."

The Onion-sowing day in Scotland was always looked forward to with considerable interest as being a very busy and eventful one, Onions in that country forming one of the main crops of the garden. This over, we felt a kind of comfort similar to that expressed in the "Village Blacksmith," "Something attempted, something done, has earned a night's repose." That the culture of the Cibouls and Leek must be of great antiquity in Scotland is shown by Scott in his *Waverley* quoting some lines in reference to the Onion and Leek, which lines Scott himself admits to be ancient; here they are:—

"There's nought in the Highlands but Syboes and Leeks,
And lang-leggit Callants gaun wanting their breeks;
Wanting their breeks, and without hose and shoon,
But we'll a' win the breeks when King Jamie comes hame."

To the English reader I think it right to explain that sybo is the general name throughout Scotland for young Onions.

To account for the antiquity of the cultivation of the Leek and Onion in Scotland, we may, perhaps, be allowed to draw on a rather sounder basis than that of imagination, which is, in the belief held by some people of good education, that a portion at least of the "lost tribes of Israel" made their way to the north of Scotland, and that they may have brought those cherished culinary esculents with them; or, what is more likely and probable, that when arrived and settled in Scotland, they may have renewed a yearning after the Cucumbers, and the Melons, and the Leeks, and the Onions, and the Garlick, which they did eat in Egypt freely, but could not have in the Wilderness, or in Scotland either on their arrival. So as soon as they found an opportunity they would no doubt send for them. People from the east in early days used to visit the coast of Cornwall for tin, and it requires no great stretch of imagination to suppose that both Leeks and Onions may have arrived in this country by that way; from Cornwall to John o' Groats is not after all a very far cry. To strengthen the above theory of the presence of some of the lost tribes in the northern cities, we may be allowed to fall back on the generally acknowledged fact that no modern Jew ever succeeds in business up there.

Having said so much as to how the Leek and Onion may have obtained their geographical distribution, we might perhaps still further be allowed to ask whether our present representatives of the genus *Allium*, as grown in this country, are superior or inferior to those of the same genus as when cultivated in Egypt during the occupation of the Pharaohs, some 4,000 years ago or thereabouts. I am aware that this is a difficult, and I may also add, a very delicate point to argue upon; for be it remembered, these lines may be read by our leading Onion-growers and distributors. These "firms" have all their own very "special superb strains" of Leeks and Onions, and of everything else besides, certified on the trial grounds of the Royal Horticultural Society's gardens at Chiswick, and afterwards exhibited at the Society's Drill Hall meetings, when they of course obtained First-class Certificates, and Medals too, of which like Indian shawls, the supply seems to be inexhaustible; after all this I am afraid the Leeks and Onions, &c., of Egypt, would make but a poor show. *W. Miller, Combe Abbey, Coventry.*

STAPHYLEAS.

To the student of the geographical distribution of plants, the Staphyleas are interesting in two ways. In the first place, although a small genus of some seven or eight species, it extends round the whole of the north temperate zone; secondly, each species has its own particular locality, no two overlapping, occurring on the same area. Starting from the eastern shores of the Atlantic, we have first *S. pinnata*, which is a native of South-western Europe and the Orient; then comes *S. colchica*, confined to the South Caucasian region; and, still proceeding eastwards, *S. Emodi* is reached in the Himalayas and Afghanistan. *S. Bumalda* and *S. holocarpa* carry us to the genus to the Pacific Ocean, crossing which to the shores of Western North America, we find *S. Bolanderi* and *S. mexicana*. Finally, *S. trifolia* on the eastern side of North America brings us back to the Atlantic again.

The Staphyleas are usually shrubs, but are occasionally found large enough to be described as small trees; they have opposite leaves and branches, the leaves being always compound generally consisting of three leaflets, but in some species five or seven, the terminal leaflet being stalked, the side ones nearly or quite sessile. The flowers are always of some shade of white, sometimes pure, at other times tinged with green or rose, and are borne in erect or drooping, terminal racemes. The seeds are enclosed in variously-shaped capsules which being inflated, have given rise to the popular name of "Bladder-nuts." All the introduced species are vigorous growers, and thrive in rich loamy soil. To get them to flower at their best, a sunny open position is essential. *S. colchica*, *S. pinnata*, and the hybrid *S. Coulombieri* are really handsome flowering shrubs. The others have little beauty in their flowers, but are handsome, robust shrubs, and interesting because of their fruits. They can all be propagated by layers, or by cuttings put in when the wood has become moderately firm—say, in July or August.

S. Bumalda.—Of the four species of Staphylea at present in cultivation, this is the least ornamental, and the smallest in stature. It is a shrub 5 or 6 feet high, of vigorous growth, and perfectly hardy, but of a denser habit, and with more slender branches than any of the following species. The leaves are composed of three leaflets, which are ovate-lanceolate, toothed, the largest measuring 2½ inches in length. The flowers appear in a small, few-flowered raceme, and are white, only one-fourth of an inch long, and have both calyx and corolla erect, the latter being almost hidden by the calyx. The capsules are flat-tish, deeply bilobed, each lobe ending in a mucronate tip; the largest capsules are 1 inch across, and the seeds are about as big as peppercorns. Siebold figured it in his *Flora of Japan*, t. 95. It has also been found in China.

S. colchica.—This species is, without doubt, the finest of all the species of Staphylea, and in recent years has acquired considerable popularity as a shrub for early forcing. With a little heat it can be had in bloom at New-year time. It is a native of the South Caucasian region, and is a shrub 6 feet to 10 feet high, whose leaves consist of three (sometimes five) leaflets, which are 1½ to 3½ inches in length, ovate-oblong, the upper surface bright green and quite smooth, the lower one with a slight pubescence. As in the other species, the lateral leaflets are almost or quite without stalks. The flowers appear in early May, in broad compound racemes; the sepals are white, and, unlike those of the other species, are fully expanded, or more or less recurved, which adds greatly to the apparent size and showiness of the flowers; the petals are pure white or faintly rose-tinted, and are erect, recurving only at the tips. The flowers are each about 1 inch in diameter, and very charmingly fragrant, the perfume suggesting that of Orange flowers or Tuberoses.

S. Coulombieri ×.—*M. E. André* originally described this plant in the *Revue Horticole*, 1887, p. 462, as a hybrid between *S. colchica* and *S. pinnata*. It had, however, been cultivated by the gentleman after

whom it is named ("M. Coulombier père, l'un des plus habiles praticiens de Vitry, Seine") since, 1872. Perhaps the most marked characteristics of this shrub are its sturdy vigour, and the abundance of its leafage. Whilst intermediate in many respects between its parents, it suggest *S. colchica* the more strongly. The racemes are more compact and less branched than in *S. colchica*, but the flowers (which are large and pure white) although showing the influence of *S. pinnata* in their more rounded form, have the sepals more expanded. The leaves are perfectly smooth and have three or five leaflets. It has flowered at Kew annually for five or six years past, and may be described as at least equal in beauty to *S. colchica*.

S. pinnata.—Next to *S. colchica* this is the most attractive of the *Staphyleas*. It comes nearest to it also in relationship and in geographical distribution,

with in a wild state as a small tree, 15 to 20 feet high. Loudon observes that the seeds are in some parts of Europe strung for beads, and that the kernels have a Pistachio flavour. The seeds ripen well in ordinary seasons; they ought to be sown soon after gathering, as they lose their vitality rapidly.

S. trifolia (American Bladder-nut).—Although not particularly common now-a-days, this species has been in cultivation in England for more than two and a half centuries. It is an interesting plant, ornamental more in regard to its foliage and habit than its flowers. Naturally, it appears to be a shrub 6 feet to 10 feet high, but it can, by removing the lower branches and by keeping it to a single lead, be made to form a pretty little tree. The flowers are produced from early May to July in short, pendent, racemose clusters, and are white, scarcely half-an-inch long, with the sepals and petals erect,

and corolla erect, each one is about $\frac{1}{2}$ inch long with the stamens exserted. Small although the flowers are, the bladderly capsules (on specimens in the Herbarium at Kew) are $2\frac{1}{2}$ inches long.

S. Emodi.—According to Sir Joseph Hooker this is confined to a narrow range in the Himalayas and Afghanistan. It is a small tree with a spotted bark, trifoliate leaves, and small flowers densely borne in cymose clusters. The species is remarkable for the size of its leaflets, some of which are 7 inches long by 3 inches broad, also for the large bladders surrounding the seeds, some of which are 3 inches long. Dr. Aitchison, who found it in Afghanistan in some deep gorges of the Shëndtoi ravine at elevations of 8,000 to 9,000 feet, says that the branches, whose olive-green bark is splashed with white markings, are carried by the natives as a protection against snakes, because of the resemblance they bear to the skins of these reptiles. Judging by dried specimens and descriptions, the species would be an acquisition if it proved hardy.

S. holocarpa and *S. mexicana* are the two newest species—of them little is known; the former is a shrub 10 feet high and a native of China, whilst *S. mexicana* is a tree that has been discovered in the forests of the southern part of Western North America. W. J. Bean, Kew.

FIG. 142.—PTERIS SERRULATA VAR. GRACILIS MULTICEPS: HORT. MAY.

(SEE P. 372.)

being a native of South Europe, and extending thence to Asia Minor and Syria. Although not truly indigenous to Britain, it has been found apparently naturalised here, and is the first of the series of *Staphyleas* stretching round the northern hemisphere which the eastward-bound traveller would encounter. The pinnate leaves have usually five divisions, but occasionally seven; these are ovate-oblong, perfectly smooth, and of a bright green above, whilst paler or slightly glaucous beneath. The raceme is quite different from that of *S. colchica*, being longer and narrower, and more or less pendent. The flowers, too, are very distinct, the sepals being erect, and closing round the petals, and thus forming a somewhat globular flower, half an inch across. They are white, with a faint tinge of green, and generally appear early in May. The seeds are about the size of large Peas, and are produced in comparatively small bladderly capsules. Usually a shrub 6 feet to 12 feet high, this species is said by Duhamel to be sometimes met

the latter slightly overtopping the sepals. The seeds are produced in large bladder-like capsules from 1 to 2 inches long. These capsules, as well as its stronger habit, distinguish it from *S. Bumalda*; whilst from *S. pinnata* it is as readily distinguished by the almost invariably trifoliate leaves, *S. pinnata* having five or seven leaflets. A native of Eastern North America.

Although not yet introduced to cultivation, the following species may be briefly mentioned to complete the genus:—

S. Bolanderi.—This, the representative of the genus in Western North America, was discovered by Bolander "on McCloud's fork of the Sacramento River in the neighbourhood of Mt. Shasta" in 1874. It is said to be one of the rarest shrubs in the forests of Western North America. The leaves have three leaflets, and these are $1\frac{1}{2}$ to $2\frac{1}{2}$ inches long, broadly oval or orbiculate, and abruptly pointed. The flowers are in a short pendent raceme, and have the calyx

FLORISTS' FLOWERS.

THE YELLOW DUNDEE AURICULAS.

A LARGE bunch of yellow and self Auriculas and coloured Polyanthus sent me by Mr. D. Storrie, of Dundee, are remarkable for their luxuriant growth and thick flower-stems, some of them 18 inches, and more, in length. There must be virtue in the soil from which Mr. Storrie produces such enormous trusses. He states that he has a deep but somewhat stiff loam, and this, in combination with the climate, suits these plants well. The fragrance in his yellow Auriculas is particularly striking; a few trusses he sent me scent the room. My experience with the Auricula leads me to surmise that the yellow self flowers, whether pale or deep in tint, are the most fragrant. The showy group of yellow Auriculas exhibited by Mr. Storrie at the last meeting of the Royal Horticultural Society were distinguished by subtle fragrance, and this was one reason why they were commended for greenhouse and home decoration. If Mr. Storrie will select his seed parents, endeavouring to obtain smooth, well-defined pips, which show a greater surface to the eye than they do when they are jagged, rough, and reflexing, he will add greater value to the welcome strain he has obtained. R. D.

FANCY CARNATION "QUEEN OF THE FANCIES."

Several plants of this fine and new Fancy Carnation were shown by Mr. Turner at the recent Exhibition in the Temple; it is one of Mr. Martin Smith's raising. It is a yellow-ground flower, with longitudinal flakes and pencillings of bright crimson, a type of which we have very few varieties indeed, the principal representative being Benary's Stadtrath Bail, upon which it is regarded as a distinct improvement. In the case of the latter, the scarlet colour is on the petal-edges, and slightly on the petals, in the form of fine pencillings, but it is not the most robust of growers. In this respect the new Queen of the Fancies shows greater vigour, and is certain to come to the head of the Fancy division. A well-known Midland amateur cultivator and exhibitor of Fancy Carnations stated that he should discard Stadtrath Bail in favour of the new variety, which appears to be emphatic testimony to its value. R. D.

PLANT NOTES.

ROSA GIGANTEA, Crépín.

THIS new wild Rose, a native of Burma, discovered by Sir H. Collett, described and named by Professor Crépín at Brussels, and figured in the *Gardeners' Chronicle*, July 6, 1889, p. 13, is now, as already

noted in these columns, in blossom on the south façade of the Château Eléonore at Cannes, the residence of Lord Brougham and Vaux. It is a splendid plant, combining with vigorous growth a shining foliage, and the beauty of its noble large cream-coloured or slightly yellow flowers, turning nearly white before falling; they reach a diameter of nearly 6 inches. The large buds are of a rich deep golden colour.

It is difficult, without being a specialist in Roses, to make out its nearest affinities, and to say exactly the group to which it belongs. But I think that its best place is among the Banksianæ of Mr. Baker's classification of "Garden Roses" (*Nicholson Dict. of Gard.*), though the stipules are much more adnate than in the *R. sinica*, which it most nearly resembles.

The long rambling branches of *Rosa gigantea* are quite glabrous; greyish-green, but on the side exposed to the sun light-brown, armed with distant irregular prickles, often in pairs at the base of the leaves, especially on the lower ones. The hooked prickles are of moderate, nearly equal size, grey or brown, and rise from a long elliptical base.

Leaves 3 to 5 inches long, 5 to 7-foliate, glabrous, dull shining green on the upperside, paler on the underside. Leaflets elliptic or lanceolate, acute, finely but sharply serrated, with a distinct red border, and becoming larger in size, thus the end leaflet is the largest. Rachis armed with some red small prickles, and with distant glands. Stipules small, adnate, not or nearly half as long as the petioles, the margin densely covered with small red glands.

Flowers solitary, shortly peduncled, calyx-tube hemispheric, quite smooth; sepals long, entire, acute or ending in a leaflike point; outside green, tinged with red, inside white pubescent, margin glandulous, with glands of different length.

Petals large, broad, imbricated, yellowish-white. Disc large, styles much exserted, free, villous, stamens long. Fruit?

A distinct species, and from the size of the flowers, their colour, and the beautiful vigorous foliage, one of the most desirable of wild Roses. It is said, however, to be somewhat more delicate than others, and more subject to mildew. *A. Berger, Curator, La Mortola, May 2, 1898.*

THE WEEK'S WORK.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower, Burford, Dorking.

The East Indian and other warm Houses.—The majority of the plants in these houses being in full growth, a generous growing temperature should be maintained in them, employing a considerable amount of fire-heat at night in order that the warmth will stand at about 75° the last thing at night. As soon as the warmth increases in the early morning, thoroughly damp down, and when the warmth has risen 5° or 10° by sun-heat, a slight amount of ventilation may be afforded, not, however, lowering the temperature, but just to admit some fresh air. The air may become comparatively dry towards the middle of the day in order to consolidate the tissues. Let the house be closed between 2 and 3 p.m., and at the same time draw up the blind on the lighter side, and thus allow the temperature to be raised by sun-heat to 80° or 90°, damping the floors, especially behind and beneath the hotwater-pipes, and between pots and stages. Many species of deciduous *Dendrobiums* being now in full growth, with growing shoots freely making roots, the syringing of the lower sides of the leaves at closing time will be a great assistance, and free the foliage from red-spider and other insects. The *Phalænopsis*, *Bolles*, *Angræcums*, *Cypripediums*, &c., should still be shaded until the sun has lost its power for harm for the day. Plants of *Cypripedium Lawrenceana*, *C. Curtisii*, *C. ciliolare*, *C. superciliale*, *C. Stonei*, *C. Swainianum*, *C. grande*, *C. selligerum*, *C. barbatum*, *C. Hookeræ*, *C. Chamberlainianum*, *C. callosum*, *C. euryandrum*, and *C. Eleanor*, inmates of the warm division, are fast going out of bloom; and as during flowering these species make scarcely any growth, it will be advisable, when the flower-spikes are removed, to ascertain if larger pots are required by them. None of these species should be kept in a pot-bound condition, and it is advisable to repot yearly, and

afford pots one or two sizes larger. Large specimens which may have become bare of growths in the centre are the better for being divided, the dead roots trimmed off, and the divisions placed in pots of a suitable size. Let the pots be quite clean, and if new, soak them in water for an hour. When commencing operations, half-fill the pot with clean crocks, and then place in the pot a portion of rough fibry-peat, fresh sphagnum-moss, with a few pieces of tufa, arranged in orderly fashion, worked into the soil, to aid in keeping porous. Freshly-potted plants are by some gardeners afforded a great deal too much water, with the result that the roots are soon lost from decay. As a rule for general observance, it may be stated that for a few weeks after repotting it is sufficient to keep the compost merely moist, till such time as new roots push forth. When thorough re-establishment has taken place, the quantity of water should be increased by degrees.

The Cattleya-house.—The plants here will require abundant ventilation by means of the lower ventilators, and the house should be damped down about 3 p.m., at which time air should be partially excluded. Let the roof-shading be rolled up after the great heat has departed, the hour depending on the position and lay of the house.

Mexican Division.—The plants in this house require only a very thin shading. Let the house be treated in the manner recommended for the East Indian-house, and afford *Lælia anceps* and others like it overhead syringings at closing time. By day the plants should be freely afforded air, and some amount may be left at the top and bottom at night in favourable weather. The temperature should gradually decline to 65° by the morning.

Intermediate-house.—The degree of warmth in this house should be slightly below that of the *Cattleya*, and a trifle higher than the *Odontoglossum*-house.

Cool-house should be freely ventilated when the external air is cool and moist, but with a drying wind blowing by day it will be better to dispense with ventilation at the top, although at night plenty of air may be admitted, the lower ventilators being kept wide open. Fire heat will not be necessary for the present. Be careful not to admit strong sunshine to the plants, and do all that is possible to keep the warmth several degrees below that of the outer air.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener, Strathfieldsaye, Hants.

French Beans.—These plants, if they are sown thickly in the drills, should be thinned to about 6 inches apart, and afterwards the soil should be drawn up to them on both sides, and the intervening spaces hoed. A sowing of the *Negro Long-pod*, *Ne Plus Ultra*, or *Canadian Wonder* varieties, made at about this date, will afford a supply till the latest date that Beans can be had in the open air.

Scarlet Runner Beans.—If these plants are grown without stopping the points of the stems, sticks are needed almost as soon as the plants appear, the sticks being long or short according to the mode of treatment; that is as ordinarily-grown, sticks of 7 to 8 feet will suffice as supports, but if grown in manured trenches 10 to 12 feet will not be too tall. In light land a mulch of litter laid along the rows is necessary. Another sowing may be made during this month.

Capsicums and Chiles.—Plants raised from seed sown in the month of March, carefully grown-on and hardened-off, may be planted out in the southern parts of the country when warm weather has come, choosing the warmest spot for them, and a light, rich soil. Let the plants be freely syringed for a time in order to encourage growth, and to keep red-spider at bay.

Garden Swedes and Turnips.—A small sowing of *Laing's Garden Swede* may now be made in the same manner as Turnips. It is a vegetable useful in the spring, when Turnips of good quality are unobtainable. Turnip-seed should be sown frequently up to Midsummer-day. The land for the crop should be well prepared, and a sprinkling of guano or fresh wood-ashes or charred soil should be afforded the plants just when they are germinating. The plants should be thinned before they spindle from being crowded.

Vegetable-Marrows may still be planted, choosing for them a spent hot-bed or a manure-heap, and affording the plants a good bed of rich soil in which to grow, as the more luxuriant the growth the larger the crop.

Potatoes.—Potatoes with us are making quick growth and earthing-up is become necessary with the earlies and second earlies.

Winter Brassicas.—If Broccoli, Borecole, Savoy, and Brussels Sprouts have been sown thickly, either in drills or broadcast, pricking off will be very necessary in order to have the plants in a fit state to stand when the time comes. Let a sufficient number be pricked off so as to leave a margin for rejected plants.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener, Woolverstone Park, Ipswich.

Greenhouse Climbers.—Timely attention should be given to thinning out superfluous shoots, and adjusting and tying the remainder in such a manner that they are seen to the greatest advantage. Plants fastened to walls and pillars should have all the main growth securely tied in, and the lateral shoots allowed to grow in their natural manner. Should the growth be rampant, and likely to become an entangled mass, thin it out boldly, so as to permit of strong development and abundant flowering. This advice applies chiefly to *Plumbago capensis*, *Trachelospermum jasminoides*, *Solanum jasminoides*, *Cestrum* (*Habrothamnus*) in variety, the *Jasmines*, *Hoya carnosae*, *Lonicera*, *Kennedya*, &c. For *Asparagus plumosus*, and *A. tenuissimus*, *Myrsiphyllum asparagoides*, *Lapageria*, and plants of similar habit, it is necessary to untwine the growths from about the wires, and tie them in evenly over the area to be covered, for when allowed to grow for any length of time without this kind of attention it is difficult to carry out the work without breaking and damaging the growths. Water should be copiously afforded to the borders and potted plants. Some climbers are liable to be attacked by Thrips, which rapidly soil their appearance if not eradicated when first noticed. The best remedy to use against them is Richard's XL All Liqueur.

Liliums.—Plants which are in need of staking and tying must be attended to without delay; and let a sharp look-out be kept for green-fly, dusting the plant with tobacco-powder or fumigating them if the pest be present. Lilies should be afforded weak manure-water frequently, and be placed in a cool, airy house or pit, and upon a moist base. If any of the plants are to be retarded in regard to their flowering, place them in a cool, airy shed and they will keep in a fresh condition for a considerable length of time.

Pandanus Veitchii.—A good stock of healthy young plants is invaluable in establishments where much room and table decoration is required of the gardener. For increasing the stock of this plant take any well-coloured suckers that may be showing at the base of an old plant, and detach them by screwing them round; then smooth the end of each with a knife, removing a few of the basal leaves, so as to allow the roots a ready passage, and insert them singly in small, deep pots, using a light sandy soil, and placing them in the propagating-box. Only bright, well-variegated suckers should be taken, for dull-coloured ones seldom make nice-looking decorative plants. The variegation is best preserved by using a rather poor sandy soil when repotting them. *Pandanuses* delight in heat and moisture, but a slight amount of shade should be afforded them during the hottest part of the day.

Plunging Plants Outdoors.—By this date most of the bedding plants being planted, time will be found for the removal outdoors, after a careful course of hardening off, of *Salvias*, *Eupatoriums*, zonal *Pelargoniums*, *Cytisus*, *Correas*, *Coronillas*, *Epacris*, and greenhouse plants generally. It is advisable to plunge these in coal-ashes, so as to economise watering and maintain the roots in a cool medium, and an equable state of moisture. Strong-rooting plants should have a piece of slate placed under the bottom of the pots, and in all cases a sufficient space should be allowed between the plants to permit of due development of growth.

THE FLOWER GARDEN.

By H. WALTERS, Gardener, Eastwell Park, Ashford.

Paul's Carmine Pillar Rose.—For the covering of arches and arbours, forming hedges, or serving as pillars, this is one of the best Roses. It is a luxuriant grower, hardy, and makes good progress in a short time when the soil is of the right kind. The trusses of single flowers are borne in great profusion. The colour, as its name implies, is a very deep carmine, of a tint, which, when the sunshine is on it, has a very vivid effect. The bloom is pretty when still unopened.

Wallflowers, Canterbury Bells, Aquilegias, Fox-gloves, Myosotis, and Liliun pendula.—Seeds of these favourite flowers of spring should be sown this month, it being advisable for gardeners in most parts of the country to have strong, bushy plants by the autumn. Such plants start into growth more quickly than weaker ones, and get therefore well-established before winter begins. The best place in which to sow the seeds is a partially shaded border, the seeds being scattered thinly broadcast, thus avoiding the trouble and labour of transplantation into nurse-beds. The beds should be trampled lightly and made level and smooth with a fine-toothed rake, before the seeds are sown. After sowing, hack in the coarser seeds with a small rake, but let the fine seeds lay on the surface untouched, beyond a slight patting and smoothing over with a bit of smooth board or the back of a bright spade. Beyond a little thinning where the plants may have been sown too thickly, and hand-weeding, nothing else will be required before planting-out takes place.

General Remarks.—The continued cold weather is proving very injurious to many of the tender plants in the beds; and the leaves are falling from the Limes and Elms in this part of the so-called Garden of England as if we were in the month of October. All recently-planted subjects should be afforded water if the soil has got dry, doing this in the evening in preference to the morning hours. Weeds must be kept under by hand-pulling and hoeing; and on hard gravel walks weed-killer should be used; and loose-shell, spar, granite, and sea-sand walks must be kept clean with the Dutch-hoe and the rake. Lawns will need for the present almost weekly attention in the matter of mowing and cleaning up. The dead blooms should be removed from Pansies and Violas, in order to prolong the flowering of these plants. The ground should be stirred with the hoe or hand-fork around Gladiolus, and each growth secured to a neat stake; *Doronicums* should be relieved of the spent flowers and stalks. Creepers on walls should be nailed-in as growth proceeds, and if the soil in which they are planted be dry, a heavy application of water should be afforded. If the Roses trained on fences are infested with green-fly, let them be syringed with diluted Tobacco-water, or with Calvert's carbolic-soap at the rate of 3 oz. to 1 gallon of water.

HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener, Belvoir Castle, Grantham.

Peach.—The trees are making rapid growth, and the securing of the necessary shoots, and the removal of those that are superfluous will require attention at short intervals. Lateral growths must be stopped at the first joint reckoned upwards from the base, and at this point flower-buds will often form, which does not occur if the shoot is simply pulled out. Examine these and other wall fruit-trees, and apply insecticides or copious syringings with water if aphides, red-spider, &c., are discovered thereon. When warmer weather at length favours the country, the blister in Peach foliage will gradually disappear; but all badly-curved leaves should now be removed and burnt, as to leave them affords a hiding-place for insects.

The Borders.—In some localities, shallow and light soils will soon be in need of water, and especially those in which are trees this year transplanted, and the borders of south and east walls generally, at such time diluted manure-water should be afforded to those trees that are carrying full crops of fruit. If the borders are caked on the surface, slightly lift the soil with a digging-fork thrust in an inch or two, so as to let the water run in readily.

Late Strawberries.—The beds should be copiously supplied with water during dry weather, but no manure-water should be applied after the fruit shows.

Raspberries, &c.—The plantations will be benefited by having a mulch of strawy litter to keep the rain from splashing the fruit that hangs low down, and to maintain the soil in a moist state. Search well for maggots and caterpillars on Pear and Apple-trees, these creatures being very destructive to the young fruits at this season.

General Remarks.—It is now very necessary to wage war with weeds everywhere, and to stir the ground with the hoe as soon after heavy rain as it is possible to employ the tool readily, thus letting the sun's heat into the soil, and checking evaporation of moisture. All plants of Groundsel, Charlock, Shepherd's Purse, Couch Grass, and Fat Hen (*Chenopodium*), should now be collected and charred, as when merely hoed up and allowed to remain on the ground until the seed becomes fit for germination, another crop of these troublesome plants spring up.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener, Hatfield House, Herts.

The Fig-house.—Pot Figs should, when the first crop of fruits is taken, be thoroughly washed with warm-water applied with a syringe, directing it chiefly and strongly to the under sides of the leaves in order to dislodge red-spider; and should scale be present it must be cleared off the plants with a sponge and soapy-water. To encourage the second crop of Figs, afford the plants a top-dressing of loam and a small quantity of artificial manure. Afford the plants water as often as may be required, and maintain a moist air in the house, and a temperature of about 65° at night, and 80° to 85° by day, closing early in the afternoon, and generally carrying out the methods put into practice with the first crop.

Early Vinery.—After the whole of the crop of Grapes is removed from the vines, afford them a thorough cleaning with warm water applied with the syringe or engine, taking care to direct it powerfully against the leaves, so as to dislodge red-spider if present, but without injuring the former; and this kind of treatment should be repeated at intervals throughout the summer. The Vines, moreover, must not lack water at the roots, but whenever the test-stick shows the soil to be getting dry, afford it water in quantity, be the borders out or inside ones. Do not shorten or remove laterals, but let them alone in order to encourage the growth and extension of the roots. This vinery must be kept fully open night and day, excepting during storms of wind and hail.

Other Vineries.—If Grapes have to last as long as possible after they are ripe, cutting should commence with the ripest, and as soon as each Vine is cleared of its crop, it should receive a cleaning in the manner described above. Grapes to be kept for as long a period of time as possible without shrivelling or decaying must be well ventilated in fine weather, and in wet weather the upper ventilators should be closed, and the heating apparatus made slightly warm. Where Grapes are beginning to colour, and the crop is a full one, manure-water may be afforded the border when it is dry, sulphate of lime at the rate of half an ounce to the gallon of water being likewise applied as a help in colouring the bunches. When Grapes are at this stage, the Vines need careful airing, and on no account should it be stinted in amount, except it be to close the upper lights when it rains. In the afternoon, when taking off the air, let a little space be left at the top and bottom of the vinery, and throughout the night. By means of hot-water pipes maintain the required degree of warmth on dull days, and also at night, and for the purpose of preventing the condensation of moisture on the berries. On these Vines the laterals should be removed frequently, excepting Madresfield Court, whose berries crack if denudation of growths takes place, or the temperature be allowed to get low, or air be not freely afforded. As the process of colouring advances, the damping of the borders and floor may be lessened in amount. The bunches of Grapes after thinning should be occasionally examined for seedless berries, which should always be removed, and a few of the others likewise if crowding appears likely to occur. All late Grapes, whilst cool, dull weather prevails, will be the better for the continual use of the heating apparatus, thus giving firmness to the fruit and foliage, and less liability to scald when the sun does really shine.

THE APIARY.

By EXPERT.

Rendering Wax.—To most persons this part of the bee-keeper's business is troublesome and distasteful, many preferring to burn the refuse combs outright, rather than tackle the work of rendering them into wax. In every well-managed apiary there accumulates during the season a considerable quantity of refuse comb, scraps of foundation, and the pressed empty combs, which, if the apiary is of any size, will amount to considerable dimensions, and in these days of low prices and keen competition nothing connected with the bee-industry should be lost sight of. An ordinary skep of clean combs will produce about half a pound of wax; and when so many now use full sheets of foundation in the frames, nearly that amount in weight of wax can be secured when melted down again. Almost everyone who has rendered wax is agreed that whatever dishes are employed in the work should be kept exclusively for that purpose. As with other advances made of late years in the appliance trade, those for the taking of the wax have come in for a share of attention. For small apiaries, the cotlager's wax extractor, costing

about 3s., suits admirably. It is made in two separate parts; the upper dish has a perforated bottom, which holds the refuse combs. This dish fits over the under one, partly filled with water. As the water boils, the steam ascends up through the combs and melts the wax, which falls into the water in the lower dish, and when cool it can be lifted off in one cake. A larger extractor on the same principle, but with several improvements added, is also in use, and adapted for larger apiaries. Where none of these can be had, the every-day washing-pot or boiler may be utilised for the purpose of wax-rendering, thus:—First, press the combs firmly together, and tie into any coarse bag (an ordinary sugar-bag will do). Immerse this bag into the pot of warm water, so that by some means it is held down beneath the surface; as the water boils the wax will ooze out of the bag, and float on the top, and when cool may be lifted off in one cake, leaving all the refuse inside the bag. A second melting and straining through muslin into any dish or mould will make it fit for sale. About twelve years ago I had made for my own use a wax extractor, which, though plain in structure, I have found very useful. It is a square dish, 13 inches by 13 inches by 18 inches deep inside, made of strong steel-plate, tinned, and having a handle and spout; a strong perforated metal lid is made to slide down the inside of the dish to any desired depth, and held there by means of a screw. Into this dish the combs are pressed firmly up to 3 inches or so from the top, and the lid brought close down to them. Water is now added till it rises above the lid, and to every four gallons of water a dessert-spoonful of sulphuric acid (vitriol) is added. This greatly enriches the colour of the wax. As the water boils the wax is poured off into cold water, and each boiling yields from 4 to 5 lb. of wax. When all the combs are operated on, the wax is then collected and tied into a clean-washed flour-bag, and reboiled in clean water (soft water is best), with the vitriol added as before. When melted, the wax is poured into moulds and allowed to cool slowly; by placing over each dish a piece of paper to keep in the heat, this prevents the cakes from cracking. Selected pieces of white comb and the cappings gathered from the honey extractor-work, should be carefully preserved, and when these are collected in any quantity, they will yield to the bee-keeper a sample of the finest wax fit to win a prize in any competition.

VARIORUM.

COLD STORAGE OF APPLES AND OTHER FRUIT.—In 1895 the Apple crop, says the *Journal of Greengrocery, Fruit, and Flowers*, for May 28, was one of the largest ever known in this country, yet practically the whole of it was finished before Christmas, not because the whole of the fruit was wanted by that time, but for the simple reason that growers glutted the markets with it, and got in return no more than they could expect—viz., very low and unremunerative prices. At the present time there is every prospect of there being just such another crop as that of 1895. Before the fruit comes along, we should like to see home growers making a little preparation for it in the shape of cold or other means of storage, for it is only by doing this and studying the markets that the best prices are to be realised. Turn to our pages in 1895, and it will be seen that good Apples realised from 1s. 6d. to 2s. 6d. per bushel, and keeping sorts, too; while early in 1896 foreign produce fetched from 10s. to 15s. per bushel. If cold storage was adopted in England in the same way as is done abroad, many kinds of produce could be doubled in value, and less would be heard of the grumble from the grower, when he is blessed with a good harvest, that the price is so bad that the fruit does not pay to send to market.

THE TIMBER SUPPLY OF THE WORLD.—“In spite of the enormous consumption of timber,” says the *Echo*, “there still remain on the face of the globe immense areas of virgin forest. The forests of Quebec and Montreal cover a tract of country a million and a half square miles in area; the Amazon valley forests have three times that area, and those of central Africa are ten times as large. Then there are the unexplored primeval forests of Siberia, where for hundreds of miles the Pine-trees grow so thickly together as to be practically impassable.”

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, Messrs. J. & J. B. Baillière, 25, Abchurch Lane, London, E.C. 4. Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	JUNE 20	Royal Agricultural Show at Birmingham.
TUESDAY,	JUNE 22	Royal Jersey Horticultural Society's Show.
WEDNESDAY,	JUNE 23	National Rose Society's Exhibition at Bath, in conjunction with Bath Rose and Begonia Show, Ryde Rose Show.
THURSDAY,	JUNE 24	Royal Botanic Society (Lecture).
FRIDAY,	JUNE 25	Windsor and Eton Rose and Horticultural Show.
SALE.		
FRIDAY,	JUNE 24	Imported and Established Orchids, at Frotheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—61° 7'.

ACTUAL TEMPERATURES:—

LONDON.—June 15 (6 P.M.): Max., 61°; Min., 48°.
PROVINCES.—June 15 (6 P.M.): Max., 68°, York; Min., 51°, Sumburgh Head.
Dull, chilly; ungenial.

The Silva of North America. THE eleventh volume of Prof. SARGENT's monumental work on the trees of the United States has recently been issued. We have often had occasion to comment on the scope of this book, and on the masterly way in which it is carried out, so that we may on this occasion confine ourselves to a few remarks on the contents of the present volume, which is devoted exclusively to the genus *Pinus*, of which thirty-four species are described and figured. Twenty-nine species inhabit the Western States of America, thirteen the Eastern States, so that even without reckoning the Mexican and Central American species, which are at present ill-defined, the temperate and northern parts of the American continent give a home to half the known species. In Mexico and the adjacent States there are several species which require study by a trained observer in the forests themselves. Great confusion and provoking obstacles have been created by ROEHL and other collectors, who, ignoring the great amount of variation which occurs naturally, have given specific names to cores of plants (actually ninety-two), which it is now difficult, if not impossible, to identify with any feeling of confidence. These Mexican Pines are, for the most part, tender and unsuitable for growth in this country. When grown under glass, their appearance is correspondingly modified. Five species are found in Central Europe and in the Mediterranean region. One, our common Scotch Pine, is undoubtedly an aboriginal native of this country, and though

now generally planted, its remains are found widely dispersed in relatively recent formations, when, certainly, planting by human agency was not thought of. The Himalayas are covered in places with Pines of two or three species, and others are found in the mountains of Central China. From this district, no doubt, further introductions may be expected. The Japanese species made known by the introductions of VON SIEBOLD, JOHN GOULD VEITCH, MARIES, and others have been largely described and illustrated in these columns, and in the subsequently published monograph of Dr. MAYR. Whilst we do not expect to see many more species from Japan, there are very many varieties which are not yet introduced into this country, though they would be valuable accessions to the gardens of the curious. Many of these are figured in Dr. MAYR's *Monograph of Japanese Abietineæ*, previously alluded to, and one formed an item in Messrs. SANDER & Co.'s remarkable group of new plants at Ghent lately. The Canary Islands have one endemic species, *Burma* and the Philippines one each, and one species even crosses the Equator, and is found in Sumatra.

Professor SARGENT deals also with the species of the genus, as affording timber or resinous products; but upon these particulars we do not here propose to dwell. As ornamental-plants, the species of *Pinus* cannot be said to rival the Silver Firs (*Abies*), and are apt to become scraggy as they grow older. The noble forms of the young trees, the lovely tints of the expanding shoots and flowers, and the extraordinary interest attaching to the cones—indeed, to the trees generally—will, however, always commend them to the connoisseur and lover of plants.

As to the arrangement of the species, Professor SARGENT has followed almost precisely that given by ENGELMANN, in the *Transactions of the Academy of St. Louis* in 1880, reprinted in our columns on July 24 of that year. That arrangement was noteworthy for the attempt therein made to utilise for systematic purposes, more fully than had been previously done, the arrangement of the resin canals in the leaves. Sometimes these canals are close under the skin of the leaf (subepidermal), sometimes in the centre of the leaf-tissue (parenchymatous), and in other cases they are, as it is called, "internal," that is, in close proximity to the central bundle and pericycle. These "characters," when they occur, are very valuable for discriminative purposes, but unhappily, as with most other "characters," they occasionally fail us, and even when they do occur, they are apt to be variable.

Characters not alluded to in the conspectus may be found in the nature of the leaf-sheath and the number of its constituents, in the variations of the involucre scales surrounding the male flowers (which are figured in many cases in the plates of the volume before us), in the leafy or leafless condition of the young shoots, and other points to which it is not needful here to allude.

The nomenclature adopted is not always in accordance with custom or law, but this is a subject upon which grave differences of opinion exist, so that any discussion upon it here would not only be tedious but unavailing. We may therefore note the principal changes made without here expressing any opinion upon the propriety of the change. Thus, *Pinus Parryana* (1862) of Engelmann (not of Gordon), and adopted by most subsequent writers, figures here as *P. quadrifolia*, Sudworth (1897). *Pinus*

insignis is referred to *P. radiata*, and a difficulty is thus solved. *Pinus tuberculata* of Gordon becomes *P. attenuata* of Lemmon. The Pine so generally known as *inops* becomes *P. virginiana*, owing to the adoption of MILLER's name, which, as in many similar cases, had been passed over by our forefathers. Something like a gordian knot has been cut by the adoption of *P. echinata* of MILLER as the true name for the one Pine known as *P. mitis* and also as *P. variabilis*; the last-named has been a special puzzle, and it is a relief to have it thus settled, if not unravelled. Less satisfaction will be experienced at the appearance of the Pine universally known as *Pinus Banksiana* under the name of *P. divaricata*. Lastly, the *Pinus cubensis* of GRISEBACH is registered as *P. heterophylla*, the first mention of the plant apparently having been not even under a specific but a varietal name, *P. Toeda* var. *heterophylla*! To alter an established name for such a reason looks heterodox indeed.

Of the American species described in the book before us, the Weymouth Pine, *P. Strobus*, is the one best known here, and we need go no further than Kew to see fine specimens of considerable age. It was introduced to Longleat by Lord WEYMOUTH, and thence it has been widely distributed. Its western representative, *P. monticola*, a more recent introduction, has also been largely planted, but does not seem likely to possess any superiority over the Weymouth. *P. Lambertiana*, a discovery of DOUGLAS', and described by him in 1827, thrives in this country, but we have no record of its value for timber. The romantic history of this tree is given in DOUGLAS' diary, printed in the second volume of the *Companion to the Botanical Magazine*, ten or more years after it was originally written. It appears that no specimens of the magnificent dimensions mentioned by DOUGLAS are now in existence. Concerning this Pine we make the following extract:—

"In most Pine-trees there is a sameness of expression, which to most people is apt to become monotonous, for the typical spiry form, however beautiful, affords but little scope for appreciable individual character. The Sugar-Pine is as free from conventionalities of form and motion as any Oak. No two are alike, even to the most inattentive observer; and notwithstanding they are ever tossing out their immense arms in what might seem most extravagant gestures, there is a majesty and repose about them that precludes all possibility of the grotesque or even picturesque in their general expression" (Muir, *Mountains of California*).

P. divaricata (*Banksiana*) might be planted advantageously on barren sand flats near the sea, but we are not aware that this has been done. *Pinus contorta* and *P. radiata* (*insignis*) are also good sea coast plants. We must not, however, suffer ourselves to be led off by the suggestions that each species offers; it must suffice to add that we have here a first-class monograph, written by one specially qualified and specially endowed for the purpose, and that to the record of his own observations he has added what amounts to an encyclopædia of interesting notes and references.

"JOURNAL OF THE KEW GUILD."—The Kew Guild, as many of our readers know, is an "association of Kew gardeners, &c., past and present." The fifth annual report is given in the number of the Guild Journal recently issued, and as far as the prosperity of the undertaking is concerned, the motto "Floreat Kew" seems very appropriate. The

FIG. 143.—*NEPENTHES VENTRICOSA*: A NEW PITCHER-PLANT FROM THE PHILIPPINES.
(SEE P. 380.)

finances are in a satisfactory condition; the meetings are well attended, the Journal is appreciated. The number before us has, as frontispiece, an excellent portrait of Prof. D. OLIVER, whose work at Kew dates from 1858. The brief memoir appended in the Journal gives a good summary of his life's labours. Another portrait herein given is that of Miss GULVIN who left Kew in January, 1897, to take charge of the garden of J. BROGDEN, Esq., Iscoed, Ferryside, S. Wales. We read that Miss GULVIN is "the first woman to take sole charge of a garden on exactly the same terms as a man. Her success has been a source of satisfaction to all who know the nature of her undertaking, and, clever though she is, many will be surprised that one of her sex so young, should have conquered all the difficulties of a first situation which evidently was not of the apple-pie order." The charge includes four vineries, orchard-house, and Cucumber frames, with flower and fruit gardens, and five acres of kitchen-garden. Miss GULVIN writes "I have a 'lady gardener' as an assistant, and four men besides. I have already had the pleasure of winning a first-prize at a local show for vegetables; and I think I may take it that I am giving satisfaction to my employer from his having raised my salary £10 a year. Our garden is a source of interest to the craft, and we have many callers, evidently curious to know what a woman gardener can do. My staff is now quite contented to be controlled by one of the 'weaker' sex. I think that when men see that our intentions are serious, and that we are not afraid to work, they respect our efforts to find employment outside the very restricted boundary within which till recently woman's work was confined. Altogether my situation is a very agreeable one." In the Guild Journal are other notes and letters from "Kewites;" hints on "Training for India," by Mr. G. M. WOODROW; report of the opening address given by Mr. MORRIS; two photos taken and lent by Mrs. S. GOLDNEY, who has lately issued a Kew Album; memorial notices of several deceased members, and other jottings.

THE CALCUTTA BOTANICAL GARDENS.—It is notified that Surgeon-Lieutenant GAGE, of the Indian Medical Service, has been selected to fill the post of Curator of the Herbarium, Royal Botanical Gardens, Calcutta, in place of Dr. DAVID PRAIN, who has succeeded Sir GEORGE KING as Superintendent of the gardens. *Indian Gardening.*

A NEW GREENHOUSE FRUIT-TREE.—In a recent number of the *Revue Horticole*, M. ED. ANDRÉ figures a remarkable Myrtaceous plant, *Feijoa Sellowiana*, introduced by him from La Plata. It is a shrub with oblong obtuse leaves, and axillary pink flowers, each measuring about 3–4 cent. across. The four sepals are reflexed, whilst the four petals are larger, and each one hooded, white externally, pink within. The fruit is oblong obtuse, tubercled, about 6 cent. long, 5 cent. lat., highly fragrant, and agreeable to the taste. It is thought that it will prove a valuable introduction into the gardens of Provence, but the fate of *Eugenia Ugni* does not lead us to expect to see it in the markets.

THE DUKE OF PORTLAND, Master of the Horse, who underwent a rather serious operation in London some days ago, which prevented him from presiding at the dinner of the Gardeners' Benevolent Institution, has been able to travel to Welbeck Abbey, and the latest report states that he is proceeding satisfactorily.

MESSRS. SUTTON & SONS' OUTING.—A numerous party, consisting of the *employés* of the famous seed firm of Messrs. SUTTON & SONS, of Reading, accompanied by their wives, &c., took part in the usual annual excursion on Monday, the 6th inst. The party, numbering about 700 persons, was accommodated in a very fine special train arranged by Mr. WEAVER, the G.W.R. station-master at Reading. The destination was Southampton, whence the party was conveyed by the steamers *Solent Queen* and *Her Majesty*, the former to Ryde, Sandown, Shanklin, and Ventnor; and the latter to Cowes, Totland Bay, and Ryde. The QUEEN had graciously consented to permit members of the party

to visit Osborne, and the favour was gladly taken advantage of by the bulk of the party. Other attractions arranged for by the firm, included the inspection of the new docks and warehouses at Southampton, the S.W.R. steamers, and the South African liners *Moor* and *Goorakha*, then lying in the docks. The party, gratified with what they had seen, left Southampton at 8 P.M., reaching Reading in two hours. All the partners in the firm, and such members of their families as were able to do so, accompanied the party, and added much by their courtesy to the general enjoyment. In addition to providing train, steamers, &c., free, the firm generously provided each guest with a sum of money ample to cover the cost of refreshments and incidental expenses of the day.

"BOTANICAL MAGAZINE."—In the present number (June) the plates are supplied which were omitted from the May number in consequence of a fire on the premises of the lithographer. The plants figured are:—

Stephanandra Tanaka, t. 7593, a Spiræa-like shrub, the leaves of which are richly coloured in autumn, and with terminal panicles of small greenish flowers. It is a native of Japan.

Symphyandra Wanneri, a tall-growing biennial Campanula, with narrow, remotely-serrate, hairy leaves, and terminal panicles of large bell-shaped, purplish-blue flowers; t. 7594.

Kalanchoe flammea, a succulent Crassulad, from Somali-land, with obovate, stalked leaves, and numerous orange-coloured flowers in terminal panicked cymes. Kew; t. 7595.

Armeria cæspitosa, a dwarf, tufted species from Spain, with very short, linear leaves, and stalked heads of pale rosy-lilac flowers; t. 7596.

Crinum Woodrowi, Baker, a new species, belonging to the section Platyster, with broad, sub-obtuse leaves and heads of large white flowers, with long, slender tubes, scarcely so long as the narrow perianth-segments. It is a native of Central India, and was sent home by Mr. Woodrow, the Professor of Botany at the College of Science, Poona; t. 7597.

Morisia hypogæa, Gay, a pretty little Crucifer from Corsica, which may be seen annually in the alpine-house at Kew. Structurally it is very interesting, and remarkable for its habit of bending down its flower-stalks, and burying them in the soil to ripen the seed. The plant grows in little tufts of linear pinnatisect leaves, from among which the yellow flowers make their appearance; t. 7598.

Celastrus articulatus, Thunberg, a rambling shrub, remarkable for the orange-coloured aril by which the seeds are invested. It would probably thrive by the sea-side. See *Gardeners' Chronicle*, 1898, p. 28, fig. 1; t. 7599.

Philadelphus mexicanus, Schlechtendal, a species or variety hardly distinguishable from *P. grandiflorus*, except in its fragrant solitary nodding flowers, and in the plant being less hardy than the common one; t. 7600.

Orcis monophylla, Collett and Hemsley.—A species from the Shan Hills of Burma, with leaves thickly spotted with brown. The flowers resemble those of our common *maculata*. The species was originally referred to *Habenaria*, but in the fresh specimens Mr. Rolfe was enabled to discover the pouches in which the glands of the pollinia are placed; t. 7601.

AGRICULTURAL STATIONS.—According to some statistics given in the *Botanical Gazette* there are in the United States fifty-one State Experiment-stations, Connecticut and New York having two each. On the whole, there are about 50 trained botanists scattered over the land, acting either as botanists, or as entomologists, bacteriologists, mycologists, &c. Up to recently we had none, but the County Councils have in many cases accomplished that, the necessity for which we so often pointed out.

DATE PALMS IN BUSSORAH.—The *Kew Bulletin* gives some figures which will astonish those whose idea of the Date Palm is that of one bending

over a well, or perchance a group of twenty in an oasis. We ought it seems to think of millions of acres along the banks of a magnificent river covered with countless Date Palms. The Date season begins in the early or middle part of September, and lasts six weeks.

"THE CULTURE OF VEGETABLES FOR PRIZES, PLEASURE, AND PROFIT."—By E. KEMP TOOGOOD (TOOGOOD & SONS, Southampton). As the result of "extended work in this direction for nearly a century," this book can hardly fail to be reliable. The author begins with the soil, and how it should be worked, dividing the rest of his work into sections:—Rotation of crops, Garden pests, Manures, Forcing, Vegetable culture, and Monthly sowings and plantings. The whole is so well classified and put together that the desired information can be found in a moment. The volume is small enough for the pocket or bag, so will serve for occasional reference in the garden as well as for more deliberate study indoors.

"TOOGOOD'S TREATISE ON PASTURES AND PASTURE PLANTS."—(MACMILLAN & CO., London). The subject-matter of Mr. WILLIAM TOOGOOD's book will be known from the title. The contents are the result of long personal experience, aided by the study of the works of such authorities as Mr. W. CARRUTHERS, Sir JOHN BENNET LAWES, and others. Chapters, subdivided into sections, deal with the subject in the following sequence:—1, Cultural preparations; 2, Our pasture grasses; 3, Leguminous pasture plants; 4, Selection of pasture plants; 5, Buying pasture seeds; 6, Testing pasture seeds at home; 7, Sowing pasture seeds; 8, Care of new pastures; and, 9, Care of established pastures. We must not omit to mention the illustrations—some thirty five in number—diffused through and appropriate to the text.

FLORICULTURE IN EAST ANGLIA.—As a proof of the increase of this attractive and remunerative industry, one grower, Mr. E. S. OLDHAM, Wisbech St. Mary, has, during the last three weeks, sent off 1,820,000 blooms of double flowered White Narcissus, weighing upwards of 20 tons, to Covent Garden and various provincial markets. The largest number sent off in one day (June 2) was 248,256, of the weight of 2 tons 17 cwt.

BAMBOOS AT THE TEMPLE.—Mr. GAUNTLETT, of the Green Lane Nurseries, Redruth, points out in relation to our notice of his exhibit, that he was showing the numbers of varieties of Bamboo (taking the word in a broad sense) now being grown in England, and some of which hitherto unknown here were introduced by him alone. He was not exhibiting Bamboos in growth, as some of the plants were rot in foliage. Neither were the plants grown in Cornwall, but recently-imported plants. Mr. GAUNTLETT says that Bamboos in general do better in the Midlands than in Cornwall, where the summer is not hot enough to ripen the canes properly.

NYMPHÆA FRÆBELI ×.—Last autumn when at Zurich we had the opportunity of seeing a bloom of this lovely variety. It was probably the last bloom, and it was out of condition. Now Mr. FRÆBEL kindly sends us a bloom which, in spite of its long journey, shows the rich crimson petals, and the orange-stamens so beautifully, that we may rank it as among the highest, if not the highest coloured varieties.

THE WORSHIPFUL COMPANY OF GARDENERS.—Sir W. FARMER has been elected Master of this Company, and Mr. PHILIP CROWLEY, Chairman of the Fruit Committee of the Royal Horticultural Society, and Mr. RICHARD CLOUT, Upper Renter and Warden respectively.

ROYAL HORTICULTURAL SOCIETY'S ROSE SHOW: CHANGE OF DATE.—Rev. W. WILKS, Secretary, asks us to announce that the Council have changed the date of the Royal Horticultural Society's Rose Show, advertised on p. 59 of the Arrangements

for 1898, from June 28 to July 12. This alteration is necessitated by the abnormally backward state of the Roses this year.

MR. GLADSTONE'S FAVOURITE FLOWER.—Since the funeral at Westminster Abbey of Mr. GLADSTONE, Mr. ELLIS LEVER has made a suggestion that on every May 19, the anniversary of Mr. GLADSTONE's death, the Rose should be worn. The late statesman had a love of flowers, especially of the Rose, and during the summer months was accustomed to wear one in his coat. On seeing Mr. LEVER's suggestion, the Dean of ROCHESTER wrote to Mr. LEVER as follows:—"You will be pleased to read the following extract from a letter dated at 78, Harley Street, March 28, 1877, addressed to the Rev. Canon HOLE:—"The Rose is, in addition to other merits, an English flower, almost an English institution, and I am glad you have made it the subject of special study and commemoration. I remain, dear sir, yours faithfully, W. E. GLADSTONE."

THE NEWCASTLE-UPON-TYNE FLOWER SHOW.—As already announced, this show will be held in conjunction with the Northumberland Agricultural Show in the Recreation Ground on Wednesday, Thursday, and Friday, July 13, 14, and 15. This will be the largest show ever held in the North of England. A large deputation from the Council of the Royal Horticultural Society will travel from London to visit the show and make awards. Several prominent nurserymen from different parts of England have made application for space; the whole show promises to be a great success.

PUBLICATIONS RECEIVED.—*Annual Report List of Members, and Schedules of Prizes for 1898* National Rose Society.—*Official Catalogue of the National Dahlia Society*. The classified lists of various sorts of Dahlias should prove useful to amateurs, while those who intend showing at either of the Society's exhibitions should note that some of the regulations have been altered since last March.—*The Canadian Horticulturist* (Ontario), May. This opens with an article on Strawberry tests at Guelph (illustrated), and contains various shorter papers on gardening topics.—*Reports of the Botanical Department of Indiana Agricultural Experiment Station*, by J. C. ARTHUR, for 1896 and for 1897 are before us. The progress made has been gratifying, one of the most important results obtained being the introduction of the new fungicide, known in the market as formalin, which proves to be a satisfactory substitute for corrosive sublimate in the prevention of Potato scab, while possessing the great advantage of lacking poisonous properties.—*The Grain Smuts*, how they are caused, and how to prevent them; by W. T. SWINGLE.—*Farmers' Bulletin*, No. 75, U.S. Department of Agriculture.—*The Germ of Pear Blight*, by LILLIAN SNYDER (reprinted from *Proceedings of the Academy of Science*, 1897).—*The Botanical Magazine* (Tokyo) April 20, contains papers by J. MATSUMURA on Formosan Oleaceæ, Melampsoræ of Japan. List of plants collected in Mount Togakushi (concluded); and by T. MAKINO, *Plantæ Japonenses novæ vel minus cognitæ*. There are also several articles in Japanese, and some miscellaneous information.—*Nature Notes*, June, 1898.—*Die Natürlichen Pflanzenfamilien* (Leipzig), 171st Lieferung.—*Dictionnaire Pratique d'Horticulture et de Jardinage*, livraisons 70 and 71, attaining to the commencement of Trillium.—*Bulletin de la Société Française d'Horticulture de Londres*, 1897 (Bedford Street, Strand). This opens with a portrait and brief memoir of Mr. C. Harman Payne, and contains also a Report (satisfactory) of the Society.

NEPENTHES VENTRICOSA, BLANCO.*

Two Philippine species of *Nepenthes*, *ventricosa* and *alata*, were described by Blanco in 1837, and have been well known from dried specimens ever

* *Nepenthes ventricosa*, Blanco, *Fl. Filip.*, ed. i., p. 807; *Hook. f. in DC. Prodr.*, xvii., p. 100.

since the exploration of that archipelago by Cuming, though nothing has been heard of them in cultivation. A short time ago, however, a plant which had been obtained from the Philippines was sent to Kew by Mr. C. Ford, Superintendent of the Hong-Kong Botanic Garden, and on comparison proves to be *N. ventricosa*, Blanco. It is a very distinct and striking plant, as will be apparent from the annexed figure, drawn by Miss Smith (fig. 143, p. 379). It is apparently more nearly allied to *N. Burkei*, Mast., than to any other, special points of resemblance being the total absence of wings from the pitcher, and the undulated peristome; yet it differs in shape, in the nearly truncate, not oblique, mouth, and in colour, as may be seen by a comparison of the figures. This latter species was originally described as a native of Borneo, but a note by Mr. Veitch in his recent paper

which the size has been taken from dried pitchers in M. Loher's collection, which, of course, were larger when alive. These dried specimens give an idea of what the plant will be like when well-grown, for one branch carries eight splendid pitchers, and others are but little less luxuriant. According to the *Appendix* previously mentioned, it is found in several localities in North Luzon.

It is too early yet to speak of its future as a garden plant, but there is no reason why it should not prove as amenable to cultivation as most of its allies, and owing to its novel shape it should prove a great acquisition, both for its own sake and for hybridisation purposes. We may hope that *N. alata*, Blanco, may yet be added to the list of those in cultivation. Now that a house has been specially devoted to them at Kew, it would be a very interesting matter to see

reproduction from this will be found at fig. 144. At the Temple Show a cultural commendation was awarded to Mushrooms from the same establishment, when clusters of small and large specimens were shown, together with a quantity of spawn. We thought, therefore, that something interesting would probably be revealed by a visit to Mr. Addey's gardens in the Ealing Rd., Brentford, and although the best of the Mushroom season was over, it was so. The house where the greater quantity of Mushrooms is grown is some 150 feet long and 50 feet wide, being 17 feet high to the ridge. There are twenty-six flat beds in this house, thirteen on either side, and on the wide path that runs through the centre are made two ridges which run the length of the house. Only the ground level in this rather tall house is thus utilised, but it used to be fitted with several tiers of shelves, since abandoned as undesirable. The use of wooden shelves Mr. Addey condemns with considerable emphasis. No Mushrooms are, however, grown in this building during the summer, but the beds will be made up and spawned about September. The rest of the houses are low span-roofed temporary-looking structures, though they are not so in reality. The roofs are of galvanised iron, but they are completely hidden by a covering of litter, and even the doorway is smothered up by similar material, there being a man-hole at the opposite end opening into the big building. It must not be supposed, though, that there is any lack of ventilation, just the opposite condition obtains. The lighted candle we carried in our hands was all but extinguished by the brisk circulation of air. This led Mr. Addey to remark that sufficient means of ventilation was one of the primary necessities in Mushroom-growing. "There must be side and top ventilation."

In one of such houses the crop was becoming exhausted, at any rate to a degree that after gathering 24 pecks from the beds, as was done on the day we were there, it was possible to compute the yield this house had given, and by measuring the extent of the beds, the crop was reduced to so much per square yard. The beds, of course, run the length of the house, on either side of the central, curiously narrow path; together they equalled a bed 57 feet long and 15 feet wide. Two hundred pecks of Mushrooms of 6 lb. each have been gathered, consequently a crop of about 12½ lb. per square yard. This is, undoubtedly, a very large return, and larger than necessary to make it a paying crop; whether any of our readers have had even greater yields, we cannot say. A similar house was inspected, in which the crop was as yet scarcely past its best, and the yield could not be accurately gauged; but as a display of growing Mushrooms, the sight was a memorable one. We may say here, that during the early summer such houses as we have described are preferred to out-of-door ridges; but there were the ordinary two-faced ridges outside, nevertheless, and good, in fact, abundant crops of Mushrooms.

Mr. Addey has been growing Mushrooms for market for nearly twenty years, and during the winter season he gathers about three-quarters of a ton each week. He has made a great number of experiments in matters of detail connected therewith, and he now declares that he has reduced the cultivation of them to a certainty. That is, he has made them a "certain" crop, and never expects, and seldom meets with even comparative failure. If this can be done in such a crop as that of Mushrooms, it must be exceedingly satisfactory to the cultivator. Of course, there have been failures years ago arising from the using of peat-manure, in conjunction with wooden shelves, resulting in an insect-pest that ruined the crop, and rendered the house unfit for further Mushroom-culture for two years; also arising from the manure being in an unsuitable condition when spawned. "But the details have been mastered since then," said Mr. Addey. We could not help thinking that Mr. Addey was more successful than some of his confrères, and we give the following hints as coming from his practice, though we are afraid he did not disclose all the little details of practice that he employs. First then, see that the manure is good,

FIG. 144.—CLUSTER OF MUSHROOMS, 5 LB. 2 OZ. IN WEIGHT, AND CONTAINING 104 MUSHROOMS.
(See article on "Mushroom Cultivation.")

(*Journ. Roy. Hort. Soc.*, xxi., p. 237), shows that it also came from the Philippines.

Mr. Veitch remarks:—"The late David Burke collected plants and seeds of two species in the Philippine Islands, one of which, a very variable but decidedly beautiful one, we are distributing under his name. Whether these species are the same as those detected by Blanco fifty years earlier is a question yet to be decided." It certainly appears different; and it may be remarked here that Blanco mentioned a third species from the Island of Cebu; also that five Philippine species are enumerated in the *Appendix* to the third edition of Blanco's work, which appeared some fifteen years ago.

To return, however, to our figure, we have to note that the pitchers are green, with the peristome rose-red, forming a very decided contrast, though whether the colour is fully developed at present is a little uncertain, for those now on the plant have not been formed under the best conditions, and have not reached their maximum development, owing to

as many as possible of the species cultivated side by side. Nineteen were mentioned as growing there in a recent note in the *Kew Bulletin*, not to mention hybrids, and it is an interesting circumstance that a striking novelty has been so quickly added to the list. *R. A. Rolfe*.

MARKET GARDENING.

"CLUSTER" MUSHROOMS.

NEXT to Mr. Featherby's stall in Covent Garden Market, where his famous Kentish-grown Grapes and Peaches are sold, is the stand belonging to Mr. Robt. E. Addey, of Brentford, one of the most successful growers of Mushrooms for market supply. Mr. Addey some time ago brought to this office an enormous cluster of Mushrooms, weighing 5 lb. 2 oz., and including 104 Mushrooms. A photograph was taken of this cluster by our engraver, Mr. Smith, and a

and where straw has been used; above everything see that it is not spoiled before the spawn is inserted. It is needful to bring it into a sweet condition, and to know that it will not heat afterwards to a greater degree than will be good. But in doing this, said Mr. Addey, most growers ruin the manure as a growing medium for the fungus. It is turned too many times, and the loss of nitrogen (ammonia) and moisture incurred is extravagant. The Mushroom is composed in a large measure of these two elements, and the crop obtained from the beds is almost always less than it would have been had there been more moisture in the manure at the time of spawning. This lost moisture can never be satisfactorily supplied afterwards. When making your beds the manure should not be so wet that when squeezed in the hand water will run away from it, but it should be sufficiently so to make it bind together. Mr. Addey turns his manure once or twice, then puts it up into rough ridges (do not lay it thinly over the ground as you would fruit that it is desired to keep), and covers it with litter for a few days.

The spawn-bricks are broken into six pieces, and these are not buried deeply in the manure, but placed so that they are exactly level with the surface of it, and covered only by the surfacing of soil, which should not be beaten to such a degree as if the object were to make it air-tight. If the spawn be broken much smaller and the bed rises a little more than it should do, the spawn will perish, but a larger piece would probably only suffer on the exterior. When the bed has been made and before spawning, it should rise to 120° or 130°, possibly to 140°, but before it is spawned it should drop to 70° or 75° if during summer or for inside beds, whilst for out-of-door ridges in winter it may be spawned at 80°. Nothing should be left to chance. Mr. Addey does not use the ordinary plunging thermometer, nor yet draw a stick from the bed to ascertain its warmth, but he uses Dr. Forbes' glass thermometers, and these are exceedingly sensitive. Of the necessity for proper ventilation we have already spoken. There is one characteristic of Mr. Addey's system of cultivation that needs special mention. It is that of "cluster" Mushrooms in the manner of that illustrated, but generally, of course, much smaller in size.

"To what do you attribute the production of these clusters?" we enquired. "To the strong, vigorous quality of the spawn used, and the condition of the manure at the time of spawning being just that required." "What advantages have the clusters?" "They prove that the spawn has come away; that it has not run about the bed; there is a heavier crop, and it is not so long about as when clusters are absent from a bed."

This is Mr. Addey's system, or as much of it as we could induce him to disclose. For many years past as much as 1500 bushels of spawn have been used each season. He now proposes to manufacture spawn for sale, as well as for his own consumption. During summer the spawn-making is carried out, and we observed hundreds of bushels about the place in various stages of development. This spawn is to be known as "Virgin-Track," and considerable emphasis is laid upon the disadvantages resulting from spawn-bricks which have been "tracked" with spawn from other bricks instead of virgin spawn from manure, which Mr. Addey describes as a species of in-breeding.

When will the present system of Mushroom cultivation be succeeded by "pure culture," such as is practised in the laboratory? When once this becomes practicable, and the actual spores are sown on glass or other shelves, and fed with chemical solutions, Mushroom cultivation will be a very different matter from what it is to-day, and the attendant circumstances less disagreeable to the fastidious and too enquiring mind of many persons who now eat the produce with a certain degree of timidity. P.

HOME CORRESPONDENCE.

MICROBES IN WATER.—Your correspondent, "W. J. Fife," in his article on "Microbes in Water, and the Damping-off of Cauliflowers and Stocks," p. 366, seems to have taken (like many others) quite

a detrimental view of these minute organisms, and their relations to plant-life. I myself think there is no need whatever to observe them in this light, and that, far from being detrimental, they are absolutely essential to the growth of plants. It seems foolish, too, to suppose, that the fewer microbes there are in the water given the plants, the less will be the damping-off. Now, it is well known that the soil itself contains these organisms, and that they are necessary to bring about nitrification; in fact, some agricultural scientists assert that it is really the bacteria which act as the active transport agency between the plant-food and the plant-root. Far better would it be, I think, to look to the fungi for a solution, as it is known that any damp, cold, or stagnant position may be the breeding-place of fungus-spores, and it is very probable that the contact of cold water with the organic matter in the soil will produce a fungus which causes damping-off. *Sidney A. Stein.* [There are microbes and—microbes. Ed.]

CARNATIONS, MANURING, AND WIREWORMS.—We have found out during 1897 two things in connection with the culture of the Carnation, which I think may be of service to your readers. The first is a method of satisfying the voracious appetite of the plant without producing the evil effects of indigestion; the second, a means of protecting layers from the wireworm. Everyone who has grown Carnations must know the difficulty of using manure sufficiently "green" and rank to afford the necessary sustenance to the plant, for if such manure is put around the roots the certain result is that the foliage will turn yellow and sickly, and the plants are practically "killed by too much kindness." Most growers, therefore, use manure only when spent, such as from an old hot-bed, when divested, of course, of a greater part of its nourishing power. We have gained most satisfactory results from placing a thick dressing of rich, rank manure at least 6 inches below the roots of the plants when put into the ground. The result is that they have to go and fetch their required nourishment, and it is abundantly clear that, when so planted, they may be trusted to take only what is necessary for their maintenance in full health and vigour. Nearly a year's experience has convinced me that this may be done with perfect safety, and without fear of producing the evil effects which accompany the placing of rank manure in juxtaposition to the roots of the plant. With respect to the wireworm, I find that the use of "Mustard waste," or the chaff and refuse of Mustard seed, is a complete protection. Last year, in layering, we commenced operations by placing round each plant a layer of this "Mustard waste" about three-quarters of an inch thick, and over and upon this was placed the ordinary layering soil. The result was a complete immunity from the attacks of the wireworms, which could not penetrate the protecting "floor" of Mustard waste. A certain number of plants were layered, as usual, without this protection, and of these we lost from 50 to 75 per cent. of the layers. The idea did not originate at Hayes, but was suggested to us by Mr. Edmonds, of Westersham, who supplied us with the Mustard waste, and who has my grateful acknowledgments. The process is so simple, and the results so entirely satisfactory, that I feel I should communicate it to your readers without further delay. The Mustard waste appears to act as a stimulant, as the layers rooted freely into and through it, and were distinctly better rooted than on plants to which it had not been applied. *Martin R. Smith.* [The beneficial agency of Mustard in some form or another in warding off attacks from wireworm has long been known to cultivators, and was discussed in these columns on March 6, 1897. Ed.]

THE CRYSTAL PALACE FRUIT SHOW.—I am delighted to find that the Royal Horticultural Society has done the right thing in the matter of grouping counties in the competitive classes of fruit. That fact alone should bring a large display of fruit, for, as you well say, what chance has an exhibitor from Staffordshire or Yorkshire of winning a prize when showing against growers from Maidstone. But I opine the Royal Horticultural Society might have gone a step further and made a Metropolitan class or group, taking a radius of ten miles round the metropolis, including parts of Middlesex and Essex, Kent and Surrey. To do this would ensure strong competition in the class. J. P.

THE MISSING ORCHIDS.—I hope the R.H.S. will pay heed to the suggestion of "S. S." on the loss of M. J. Jules Hye's Orchids, and close the show earlier on the last day; also to Mr. C. Wolley Dod's protests concerning the ventilation of the tents. For ourself,

we could not remove all of our Caladiums on the last day, and some were left to be fetched early the next day, when, to our astonishment, the side canvas had been removed from the tent, and the cold air had been driving through the plants all the night. Of course, they were spoiled, if not killed. These things ought not to occur. J. Feed.

—Whilst much fuss is being made over the loss of four or five Orchids, entirely through the neglect of the owner to take common precautions at the recent Temple show, no one seems to have thought it worth while to remark that out of the many thousands of plants seen there, these few neglected Orchids were the only ones lost. That is a fact the management is entitled to some credit for. There are some people in the world who seem to think that when something has to be done, to-morrow will do as well as to-day. That seems to have been the dominating idea of the owner of these lost Orchids. Most persons owning what seem to have been exceptionally valuable plants would have set about securing them the moment the show closed, yet we have been told that three hours later the plants were still safe on the tables, and it was not till yet another hour had elapsed that any effort was made to pack the plants. What earthly value in such case would it have been to have closed the show an hour earlier ere visitors paying at the gate at 4 o'clock could not have seen the whole. But is not the observation of "S. S." most unjust when he remarks, "that those who pay for entrance after that hour include some who avail themselves of the opportunity of laying their hands on anything." Is not such a suggestion a monstrous calumny? Does he assume that some such visitor, biding his time, coolly took the lost Orchids in his arms, and marched with them out of the gate, and so away? That is too absurd an idea. The Orchids must have gone in some vehicle, or they would have been noticed. Surely it may not be difficult to reduce the range of suspicion to a reasonable area. It is hardly probable the plants were carried off without some employed being aware of what was done, and it may be possible to get at that knowledge, and so find the thief, if the Royal Horticultural Society and the British trade combined offer a very tempting reward. The value of the plants is a minor matter compared with the unearthing of the thief, and having him exposed and punished. When it is urged that earlier closing would prevent plants being thus surreptitiously removed, I must ask how it is possible to prevent any similar occurrence in the future, unless the owner of the plants or his servants are there to look after them. When we remember how many hundreds of flower-shows are held yearly, and how many hundreds of thousands of plants, &c., are concerned, then how rarely anything is lost, is it enough to base on the loss through owner's negligence in one case of a few plants, a demand on all horticultural societies that they should close their shows earlier? The impression is now prevailing that very much more fuss is being made over this incident than it merits. A. D. [We feel the disgrace too keenly to assent to this proposition. Ed.]

—With regard to the lost Orchids, the suggestion from your correspondent "S. S." to close shows earlier, is undoubtedly a good one, but it does not appear to strike at the root of the matter. Would it not be advisable in the future for the Royal Horticultural Society to supply special badges to each exhibitor, one for himself and one for every assistant, to be worn directly after closing time? Then, by giving strict orders to the police to clear out any person not wearing the badge, the risk of loss to exhibitors, who would, of course, see that the badge did not fall into other than trustworthy hands, would be reduced to a minimum. A. F. T.

WHITE CABBAGE - BUTTERFLIES, AND THE SCHOOL CHILDREN.—We are afflicted here, in Moulton, South Lincolnshire, with a perfect plague of white butterflies, and we know what that means so far as the Brassica family are concerned. I therefore went into the Board Schools the other day and told the children that I would give a penny a score for as many of these destructive creatures as could be supplied; the result is they are coming in at the rate of 100 a day. The benefit which this will be to the Brassica family in the neighbourhood is incalculable. R. K. [It will pay to set the children to smash the colonies of eggs that are laid by the butterfly on the undersides of the Cabbage and Cauliflower leaves; a hundred eggs may be destroyed with one or two nips of the finger and thumb. Ed.]

NEPETA GLECHOMA VARIEGATA.—This hardy variegated trailing species—in the vernacular, ground

Ivy—is seldom grown as a garden plant, although a desirable subject for planting in vases, window-boxes, &c. for spring and summer effect, as drapery for the sides of these. When a plant is placed in slight warmth, all cuttings made of the shoots strike readily at this season. It is a plant that is adapted for the rock garden. I noticed some baskets covered with this plant at the Royal Horticultural Society's meeting on April 12, exhibited by Mr. C. Turner, Royal Nursery, Slough. They received a Cultural Commendation; and, probably, the fact that the good use the plant was put to may help to bring the variegated form into general notice. C. H.

THYRSACANTHUS SCHOMBURGKIANUS.—It is much easier to write the old specific name of rutilans; but, as the botanist decrees this is only a synonym [?], it is well to be correct. This charming winter and early spring-flowering plant is now to be seen in great beauty in the Hassocks Nurseries of Messrs. Balchin & Sons. A native of tropical Africa, it needs stove treatment, and will be found lasting in an intermediate-house, where it has produced its long pendulous racemes. The extraordinary floriferousness of the small plants at the Hassocks Nursery is remarkable; it is, when properly grown, an abundant bloomer, producing its high-coloured flowers in great plenty, while its graceful method of displaying its racemes of bloom constitutes it an excellent table-plant. Doing well in a good light loam with some well-decomposed manure and leaf-mould added, it should be kept growing as fast as possible till the specimens become pot-bound, and then they flower all the more freely; liberal supplies of water and warmth are necessary. R. D. T. Schomburgkianus is a native of Guiana, while T. rutilans is a native of New Granada, according to the *Index Kewensis*. Ed.]

PASSIFLORA BONAPARTEA AND BOUSSINGAULTIA BASELLOIDES.—I have had a peculiar experience with these plants, which were planted out in a hothouse border, well exposed to the sun's rays, and therefore suited to their needs. As yet no flowers have appeared. I may add, that the Bous-singaultia was tried first in a greenhouse, but it was not satisfactory there. If some of those who read this note will kindly give me a hint as to what I should do with these plants, I should be greatly obliged. L. G.

PRIMULA TRAILLI.—Having had another year's experience, I can now speak with certainty as to *Primula Trailli*. I heard from my Indian botanical friend that he had met the collector of the seed sent me as that of *P. Trailli*, and he had shown him the gardening papers which I had sent to India, with figures of the plants that bloomed at Heatherbank. These, he said, were quite different from *P. Trailli*, and that he had collected seeds of other *Primulas* at the same time as *P. Trailli*, that the seed was mixed, and that of *P. Trailli* had not come up. I think that the best name for the *Primula* which I exhibited would be *P. Munroi*, or *P. involucrata major*; it is utterly unlike the form of *P. Munroi* or *P. involucrata* which I have grown for years. It has, when grown close to the glass, stems above 18 inches high, with long leaves, with no tendency to be drawn up. Probably some Indian *Primroses* have different forms. Some years ago I exhibited before the floral committee of the Royal Horticultural Society a giant form of *P. capitata*, which I suggested should be named *P. capitata major*. It received a First-class Certificate on Oct. 9, 1886. Some time afterwards a nurseryman exhibited at the Royal Horticultural Society a giant form of this *Primrose*, which I suppose the floral committee considered to be different from mine, as this also secured a certificate or an award. The committee only followed the usual precedents in awarding a mark of merit to a fine, distinct, new form of *Primula* in the case of *P. Trailli*; but I think that the name should be changed, and the fact recognised that *P. Trailli* has still to be introduced. George F. Wilson, Heatherbank, Weybridge Heath.

A GOLDEN-LEAVED CURRANT.—It is possible that objection to the introduction of one of the richest-coloured of foliage shrubs into shrubberies or flower-beds, because it is a Black Currant, and therefore a garden fruit, just as one of the most effective of bedding foliage plants has been objected to on the ground that it is but a Beet. But it is not possible to look at the few bushes of this very richly-coloured Black Currant growing in the Royal Horticultural Gardens, Chiswick, without realising that of its kind it is one of the most striking and effective of golden-leaved deciduous shrubs in cultivation. Its colour is persistent and equal. Any one wanting a groundwork of gold out of which to

have rising the dark-leaved *Prunus*, or *Hazel*, or any other red-leaved tree or shrub, would find this Currant in the summer, at least, perfect for the purpose. A. D.

PROPOSED WIDNES PUBLIC PARK AND ITS COST.—I wish to call the attention of intending competitors to the very unfair conditions issued by the committee who have this matter in hand. The most objectionable conditions are as follows:—1. Only £4000 is allowed for laying-out 34 acres of land, fencing-in, entrances, and all necessary architectural features, and the formation of a lake and planting. Anyone who has had to do with park formation well knows that this is impossible. 2. The committee ask for drawings, which would require at least four double-elephant sheets, and in addition to these six perspective-views, which are to show the park as it will appear in five years' time. All these drawings are to be sent in by July 1, showing clearly that the committee do not understand what they are asking for. 3. No assessor is named. 4. If twenty competitors enter the lists, the actual cost of their work, including expenses, would amount to £400, or £20 each. For this expenditure, the committee offer in premiums the sum of £52 10s. 5. The committee do not offer to employ the successful competitor. As a warning to the younger men, I might add that out of the large number of park competitions I have won, in only one instance have I been asked to carry out my designs. Thos. H. Mawson, Landscape Gardener, Windermere.

HOLLBÆLLIA LATIFOLIA.—In Devon the subject of this note is a perfectly hardy evergreen creeper, thriving on an east wall, and flowering annually fairly well early in May. I think, however, if our plant had been given a southern aspect better results would have followed. The flower is rather small, greenish-white, and possessing a delightful fragrance. It is a native of the Himalayan Mountains, and was introduced in 1840, and is sometimes known as *Stauntonia latifolia*. Pruning is required every year, early in the autumn, cutting back the trailing shoots, which if left untouched with the knife soon become an entangled mass, and not very productive of flowers. It is usually propagated here by making cuttings of half-ripened shoots in the summer; but last January a lady living at Paignton, near Torquay, sent to me a ripe fruit, purple in colour, oblong, and about the size of a duck's egg, which I took for a fruit of some species of *Passiflora*. The seeds were sown on January 29, and there are now twelve young thrifty plants. Last month the same lady kindly sent me flowers and foliage of this creeper, which were at once identified as those of *Hollbællia latifolia*. The mother plant bore several fruits, and is planted near a verandah, over which it is trained, and beyond being sheltered by the dwelling it is otherwise unprotected. Is it not unusual for *Hollbællia* to fruit out-of-doors in this country? and perhaps others will kindly write their experiences of it. James Mayne, Bickton Gardens, B. Salterton. [See *Gardeners' Chronicle*, Feb 19, 1876, fig. 46. Ed.]

CARMICHAEL'S PEAR-TREES AT SANDRINGHAM HALL.—I had often the pleasure of seeing and admiring the trees referred to by Mr. Carmichael in a recent issue of the *Gardeners' Chronicle*, and have seldom seen finer Pear-trees. In lecturing in East Anglia, I used to advise my hearers to take advantage of the cheap Great Eastern trips, and the free days to Sandringham, and go and see these trees; and I have reason to believe that not a few noblemen, gentlemen, clergy, farmers, tradesmen, mechanics, and labourers took my advice, and some of them are now reaping the reward of what they then saw. I shall not readily forget the interest excited at some of my lectures, when grand specimens of the Pitmaston Duchess, and the Uvedale St. Germain stewing Pear were mounted on slender or weeping Pyramids, as illustrating the effects of heavy cropping, as a most efficient and profitable means of training, &c. Few sights were more pleasing in the princely gardens at Sandringham than the fine Pear-trees planted and trained by Mr. Wm. Carmichael. D. T. F.

THE GARDEN CHARITIES.—I do not wish to decry in any way the management of these, but the system and principle on which they are carried out appears to me to be utterly wrong, and the exceedingly small number [of gardeners] who do subscribe shows that I am not alone in my opinion. A gardener is usually not a person who can afford to subscribe liberally to general charities; it needs all his care to do a little to provide for himself and his

family, and naturally, under the circumstances, his charity begins, as it should, at home. If he subscribes 5s. per annum he gets a vote, but of what use is the vote to him? practically none; all his money may, and probably will, go to someone else, and it is worth while to consider what this 5s. per annum means to him. If he begins to save this amount from the age of twenty-four, his average expectation of life is forty years more. His 5s. per annum, saved and invested at 4 per cent. interest, would, at the end of the period, amount to the sum of £23 15s. If he saved 5s. per month, it would be £285. Why should he sacrifice the certainty of £23 15s. for a simple vote? If the thing is to be a success, the subscriber, who is almost invariably a poor man, must be able to depend on some certain return for his money—5s. per annum would, if properly invested, provide him with a valuable sick and accident fund, or it would ensure his family the sum of £23 15s. at his death, whenever it occurred. Very large numbers are subscribers to sick and benefit clubs, and these are very costly luxuries indeed. Taking the very best and most liberal of the English industrial insurance offices, it will be found that, on an average for several years past, for every shilling paid in premiums, less than 4½d. has been paid back, all the remainder going in expenses, profits to shareholders, &c. What this really means none but those behind the scenes know; but it is a fact that the difference between the premiums paid to one office only, exceeded the amount paid for claims during the last year by considerably over £2,800,000. In the face of such figures as these, one ceases to wonder at the palatial offices, the salaries to officials, and the high price of the shares. Let it be borne in mind that this is only one out of a great many offices, and the loss to the poor workman will be appreciated. If a gardeners' industrial assurance can be inaugurated, dispensing with all the magnificent offices, salaries, and profits, and a fair and certain return for his hard-earned money could be depended on, it would not be necessary to make urgent appeals—they would gladly come in, in their thousands, without being asked. At present they naturally like to feel they are saving something, and the Post-office savings'-bank is their best gardeners' benevolent society. Can this be wondered at? and if I am wrong, will some one set me right? Thomas Fletcher. [It is easy to set our correspondent right on some points; there are no palatial offices, and very few and moderate salaries to officials. Ed.]

SINNINGIA (STENOASTRA) CONCINNA, S. GUTTATA, S. SPECIOSA, AND OTHERS.—Mr. Burbidge's charming illustration, and Mr. Lynch's description, almost make this old favourite grow and bloom afresh, on p. 361 of the *Gardeners' Chronicle*. Fortunately the grace and beauty of such plants, as well as their botanical interest, are pretty sure to furnish them with a welcome home in our botanical gardens. Most of the *Sinningias*, and *S. concinna* in particular, bloom so profusely that it seems impossible to find room for more blooms. Nevertheless there was, years ago, a more floriferous form of the type known as *S. c. multiflora*, with more and larger flowers than the species, and with a larger proportion of bluish-lilac in the flowers. Notwithstanding the dwarf neat habit and other merits of this pretty plant, and that we have possessed it for nearly forty years, it never became common in gardens. The smaller species had to compete for public favour with several larger, and as many thought more beautiful species, such as *S. guttata*, so like as to be said by some to be identical with *S. velutina*, with its thickly spotted or dotted throat. The taller stature, larger leaves, and more varied beauty of this and kindred species, appealed more powerfully to the eye and imagination of cultivators, and suggested the possibility of pouring new forms and colours into the rather commonplace *Gloxinias* of the period through crossing them with the different species of *Sinningias*. Mr. Burbidge points out, in his useful book, *The Improvement of Cultivated Plants*, how our present race of garden *Gloxinias* began to advance by leaps and bounds from the year 1844. In that year, Mr. Carton, then gardener to the Duke of Northumberland and at Sion House, introduced four new and greatly improved *Gloxinias*. These were *Gloxinia insignis*, *G. magnifica*, *G. bicolor*, and *G. Cartoni*. The seed-bearing parent being *Gloxinia speciosa rubra* fertilised with the pollen of *Sinningia guttata*, *Gloxinia maculata*, and many others followed. Other species of *Sinningia*, such as *S. speciosa*, in its several varieties, with upright flowers and long drooping leaves; *S. conspicua*, and others, were doubtless used with

more or less effect. Having fixed most of the finer forms, colours, markings of the finer Sinningias in our modern Gloxinias, the Sinningias themselves have mostly been relegated to back places in, or disappeared from private gardens. It is hoped, however, that sufficient species and varieties remain in our botanic gardens to show the rising race what Sinningias are like, and also to prove their potency in the improvement of Gesneras, which have made comparatively little progress in the period that has witnessed such an enormous development in the Gloxinia. I still believe—in these days of glitter and glare, and all too exclusive provision for excessive cutting and crushing together of flowers for decorative purposes—that a small choice collection of Sinningias are worth growing for their own sake, as well as for their probable potency in the improvement of closely-allied genera or species through cross-breeding, &c. D. T. F.

THE PRESENT PLAGUE OF INSECTS.—The appended poetic effusion was taken from the June number of the *Agricultural Economist*, which seems to have taken it from another contemporary, and by its wording and phraseology I should think it came originally from the U.S.A. For its truth and practical wisdom it is worth repeating. Despite a showery May, and a host of rooks and starlings, insect-pests are very prevalent, and the tops of the Oak-trees in the adjoining woods are getting brown and bare from the ravages of looper-caterpillars, and the same species are turning their attention to the Apple-trees; but we must, in the words of the poet, "keep a fightin'," and, I hope, successfully. The remedy that we use is as follows, viz.:—3 oz. Paris Green in paste, 2 lb. sulphate of copper, 4 lb. of lime, dissolved separately in earthen vessels; and 25 gals. soft-water, all being mixed together in a wooden tub, then strained, kept well mixed, and applied by a Vermorel spray-pump. I can recommend the above mixture as being both safe and effectual. We have about 9 acres of mixed orchard, principally Apples; we have a good set of fruit, and between the rows of Apples we have "lands" 16 feet wide planted with Potatoes, and the diluted Bordeaux Mixture used with the Paris Green acts as an antidote to the Potato disease.

CANKER WORMS.

Have you canker worms or Pear slugs?
Keep a-fightin'!
Saw flies, codlin moths or plant bugs?
Keep a-fightin'!
While you're foolin' round, they're feedin',
While you're cussin' 'em, they're breedin',
A good pizen's what you're needin';
Keep a-fightin'!
You will want some Paris Green, sir,
Keep a-fightin'!
Insect-powder, kerosene, sir,
Keep a-fightin'!
Oh, these bugs 'll keep you humpin',
With their hoppin', skippin', jumpin',
What you've got to do is *pumpin'*;
Keep a-fightin'!
Butterflies, an' gnats, an' millers,
Keep a-fightin'!
Beetles, bugs, and caterpillars,
Keep a-fightin'!
Be they plump or be they flaccid,
Hellebore, arsenic, acid,
Are the things to make 'em placid;
Keep a-fightin'!

R. M., Newbury, June 13. [The greatest care should be taken in the use of such poisonous substances. ED.]

VEGETATION IN THE NORTH.—While all the foliage of forest trees, and the flowers on many of these are in great beauty, and by no means late, quite the reverse is the case with the Ash, many of which have scarcely any leaves on them at all, and none is in full leaf; and it seems so as far south as Lancashire. Is it so further south? W. H. Maxwell, Munches, Dalbeattie.

THE OAK CATERPILLAR OR LEAF-ROLLER (TORTRIX VIRIDANA).—I live on the borders of Needwood Forest, where, as everyone knows, are some of the finest Oaks in England, and the district generally produces Oak of the best quality. Up to 1896, although I observed occasional attacks of the caterpillar, I never knew of serious damage being done. But since 1896 the caterpillar has steadily increased and spread over a greater area until, here at least, it threatens the absolute destruction of the trees, both old and young. Now, some of your readers (if you are good enough to insert this letter) may be able to

say if violent attacks have occurred, if the trees have died, or if, as is the case occasionally, the insect, after a time disappeared. [Yes.] If the conclusion to be arrived at is, that the trees die, and the insect flourishes, the lesson to be learned is to plant some other tree as your main crop than Oak, and a very serious one it is. One thing only I have observed regarding a check to the destruction, and that is, that the rooks appear to live in the infected trees, and if it can be proved, or appears that the rooks eat the caterpillars, which I believe they do, then the lesson is, do not shoot your rooks for a few years. This strikes me as almost a national question. I do not therefore apologise for a somewhat long letter. T. J. Levett. [A good remedy is given in another letter, under "The present plague of insects." The eggs are laid in the previous summer and autumn, and being very small, are scarcely observable on the trees. Something might be done by encouraging the willow wren and the white-throats. These birds devouring the caterpillars; and rooks, starlings, pitmice, and nut-hatches, are said to be of use in the matter. ED.]

FRUIT CROPS IN EAST KENT.—The various fruit crops at Northdown are promising; Apples have set freely, some of the trees being "roped" with fruits. Peaches are a very good crop, and have already been thinned twice, and blister is not common. Currants and Gooseberries have very satisfactory crops, as also Strawberries and Plums. Pears can only be considered a fair crop. Our Apple-trees last year were thinly cropped, and some were quite bare of fruit, and this paucity gave the trees a necessary rest. The Cherry-Plum (*Myrobalana*), which fruited so very heavily last year, has this season failed to fruit, owing to frost; this is the drawback with this variety. It flowers so early; moreover, the heavy crop of 1897 may have weakened the trees somewhat. Figs are not so heavily cropped as usual, much of the young fruit, owing to the mildness of last autumn, were too advanced, and have now fallen. If in other parts of the country the set of fruit is as good as here, 1898 will be a very good fruit year. H. Markham, Northdown, Margate.

PINK-COLOURED LILY OF THE VALLEY.—It is hoped that Mr. Strong's note about this variety in a recent number of the *Gardeners' Chronicle*, will not afford a stimulus to the cultivation of this plant. The plant is greatly inferior to the pure white varieties; and it used years ago to be grown as *Convallaria majalis* var. *rubra*. Fortunately, the plant lacks the vigour of the white varieties. It is almost equally true of the double-flowered variety of valley Lilies, though, as a rule, these are mostly white. D. T. Fish.

ROYAL SOVEREIGN STRAWBERRY.—Mr. Wythes' encomium in the *Gard. Chron.* on this fine variety is being confirmed by many gardeners who gave it a trial last year and this season. In my opinion it is one if not the best raised by Mr. Laxton. I have not grown the Royal Sovereign for supplying very early fruit, and when it is not brought very fast the yield is enormous, the fruits firm, large, and of good quality, and as forced fruit they bear carriage well. In the open, young plants raised in small pots in July and planted at a foot apart in the rows on deeply worked and heavily manured ground, had very fine trusses of bloom, in some instances four and five to a plant. The fruits on June 7 were as large as full-grown Cobnuts, and would have been earlier had the plants been set out on a warmer part of the garden. I am not again going to cultivate the variety *Auguste Nicaise*, which is praised for its large size, the fruit being too soft to bear transit, and in damp weather they decay too soon. It would have served my purpose better this season had all my latest Strawberries in pots consisted of Royal Sovereign. H. Markham, Margate.

LAW NOTES.

CLAIM FOR VALUE OF GOODS RECEIVED.

At the last sitting of the Wandsworth County Court, before His Honour Judge Lushington, John Van Dillwyn and Louis Thiel, who carry on business at Meirelbeke-by-Gand, Belgium, sued the Metropolitan United Floral Co. Ltd., who have a branch at 137, Northcote Road, Clapham Junction, and a nursery at South Street, Wandsworth, to recover the sum of £42 for plants supplied. There was a set-off by the defendants of £42 for depreciation of plants, &c., supplied by the plaintiffs. The plaintiffs' case was, that they supplied the defendant company with

plants, and it was alleged that they were good value for money. It was denied that they were in any way forced or frost-bitten. The defendants admitted £26, but with regard to the balance, contended that the plants were useless, and not saleable on the English market; however, they kept the plants, and sold them for what they were worth. His Honour held that the plaintiffs were entitled to the whole amount of the claim, and gave judgment accordingly with costs. The set-off of the defendants was ignored.

Obituary.

HENRY HEMSLEY.—Mr. Hemsley, who died on June 7 last, in the 79th year of his age, was a well-known expert in the nursery trade. He was an able cultivator and enthusiastic raiser of new varieties of plants. Parson's White Mignonette is a case in point, to which a First-class Certificate was awarded in 1870. The greater part of Mr. Hemsley's active career was spent in Sussex, where he was well known. For some years past he has lived in retirement. It is now some forty years since I first made his acquaintance, he having been an intimate friend of my father, Mr. W. Botting-Hemsley, F.R.S., of Kew, and Mr. A. Hemsley, of Mr. H. B. May's nursery, are sons of the deceased. Jas. Hudson.

SOCIETIES.

ROYAL HORTICULTURAL.

JUNE 14.—The first meeting of the Committees since the Temple Show was held in the Drill Hall, James' Street, Westminster, on Tuesday last. The hall was well filled with exhibits of plants and flowers, but particularly cut-flowers. Herbaceous, perennial, and bulbous hardy plants were represented by cut-flowers in great profusion, the same things being in many cases to be remarked in more than one collection. Such popular hardy flowers as Paeonies, Irises, Rhododendrons, Pyrethrums, Aquilegias, &c. gave to the scene a decided seasonable appearance; but the first out-of-door grown Roses have yet to be shown, if we except a few garden Roses from Messrs. Wm. Paul & Sons.

It was announced before the lecture was commenced in the afternoon, that owing to the cold unless weather at present prevalent, it was proposed to postpone the exhibition of Roses in connection with the Royal Horticultural Society until July 12. The necessity of this seemed apparent in the extraordinary number of overcoats and umbrellas in the hall, a number suggestive of March rather than of June. Carnations of all sections appear to be increasingly popular, and on this occasion there was a remarkable exhibit of plants of the Malmaison type from J. P. Morgan, Esq., Dover House, Rochester. By the Fruit Committee awards were made to a new Melon, a new Cucumber, a Cabbage, and a variety of Spinach.

It is satisfactory to record that a very unusual number of new members was added to the Society on Tuesday, there being so far as we could ascertain about 108.

Floral Committee.

Present: W. Marshall, Esq., chairman; and Messrs. John Fraser, H. B. May, Geo. Nicholson, J. H. Fitt, Geo. Stevens, W. Howe, Jas. Hudson, J. F. McLeod, J. Jennings, J. Fraser, W. Bain, George Gordon, J. D. Pawle, Ed. Mawley, Chas. E. Shea, Chas. E. Pearson, E. T. Cook, Ed. Beckett, Chas. Blick, Geo. Paul, H. J. Jones, Chas. T. Drury, J. W. Barr, W. Selfe-Leonard, C. E. Cant, and T. W. Sanders.

Mr. H. B. MAY, Dyson's Lane Nurseries, Upper Edmonton, showed a group of Ferns which illustrated sixty varieties that have been raised at the establishment during the last twelve years or so. Thirty of these have already been awarded First-class Certificates or Awards of Merit by the Royal Horticultural Society. The centre plant was the new *Phlebodium aureum* Mayi, and conspicuous plants were *Gymnogramma Alstonii* superba, *Pteris serrulata* corymbosa, *Pteris tremula* elegans, *Pteris Summervillei*, *Gymnogramma grandiceps* superba, *Asplenium incisum*, *Gymnogramma flavescentis*, *Davallia fijiensis* robusta, &c. These are further noticed on p. 372, and several of them are figured in our present issue. Mr. MAY had also a pretty yellow flowering *Tropaeolum* named Sunlight, and a very large pink-flowering zonal *Pelargonium* known as Millfield Rival (Silver Flora Medal).

Messrs. COLLINS BROS., Waterloo Road, London, S.E., and Hampton, Middlesex, showed a collection of hardy flowers in bunches, including conspicuously good varieties of *Pyrethrum* Monarch, which is said to bloom one fortnight later than Hamlet. It is a very large-flowering sort, with deep pink blossoms nearly 3 inches across, and exceptionally free (Award of Merit); a very fine crimson flowering sort is Mrs. Bateman Brown. Several very good varieties of *Gaillardia*

randiflora were observed, also *Geum miniatum*, the excellent market plant *Achillea mongolica*, &c.

From Mr. Geo. Norman, gr. to Lord SALISBURY, Hatfield House, Herts, came a basket of Carnations of the two very excellent border varieties, Miss Audrey Campbell (yellow), and King Arthur, bright crimson. They were sprays only, but these were inserted into damp moss, and may have been mistaken by some for plants. The yellow variety was placed in the centre, and amidst a circle of scarlet flowers. Generally the blooms were very good in quality (Silver Banksian Medal).

The centre of the hall was occupied by a large group of *Souvenir de la Malmaison* Carnations, shown and cultivated by Mr. McLeod, gr. to J. P. MORGAN, Esq., Dover House, Roehampton, S.W. These plants were fully described in our issue for June 4, on p. 348. About thirty specimen plants were shown, and most of these bore about forty-five flowering growths each, whilst all the shoots were furnished with vigorous foliage, free of the least sign of disease. It has proved, however, to be impossible to induce the whole or even the greater part of the flowers on these large plants to expand at one time, as each plant affords a long succession of blooms. The group, therefore, did not present the floral display that smaller plants in bloom, selected from a collection and placed together, will afford, and this we were informed was the reason that a Silver-gilt Flora Medal was awarded in the place of a Gold Medal. Yet as specimens of a very difficult plant to grow successfully, they were grand, there being probably none others equal to them in this country. They were arranged in the form of a central group, and then threaded to smaller terminating groups at each end. The sides were composed of smaller plants, and amongst these were The Churchwarden, Lady Grimston, and others of deeper and brighter colours than the ordinary pink variety. Ferns were interspersed, but these were dwarf, in order not to hide the bases of the plants.

Messrs. H. CANNELL & SONS, Swanley, Kent, made an exhibit of tuberous-rooted Begonias, all of them double-flowered. An Award of Merit was recommended to a variety with very bright scarlet camellia-shaped flowers, named Commodore Dewey, an acquisition. Lady Naylor Leyland was noticed as being a very lovely salmon-pink, with fringed petals; Miss M. Bradbury is paler pink, has a larger, rather looser flower; Mrs. C. J. Whittington is a pretty picotee-like flower, but shows several centres—a characteristic we regard as a disadvantage to double-flowered Begonias; Miss M. Griffith is a pure white flower, with beautifully-frilled petals; Duchess of Montrose is one of the large yellows; Lord Lindsay is another yellow one, but has very different shaped blooms. Messrs. Cannell had also a lovely display of varieties of Aquilegias; the delicate tints of some of these varieties are now beautiful in the extreme.

H. CANNELL & SONS also exhibited a large and fine semi-circular group of the newer varieties of *Canna indica*, and among them we remarked Incendie, a flower of a scarlet ground colour, bordered with yellow, and having scarlet blotches on yellow; Paul Neylan, of orange scarlet, and furnished with a thin yellow edge; Aurora, in colours soft orange red, large; Florence Vaughan, yellow, with the entire area of the segments spotted with crimson; Explorateur Campbell, of the deepest crimson colour, and with large segments; Aurea, a self, of a soft lemon-yellow; Queen Charlotte, still one of the best of its kind, crimson, bordered with yellow; Madame Barrie, of a tint of orange-scarlet; and Conquerant, a self, of a lively deep orange tint (Silver-gilt Flora Medal).

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, obtained Awards of Merit for Cannas Mrs. W. Marshall and Mosaic. The former is a very pretty bright flower of rich yellow, with each segment and lip marked with crimson. The other variety has a yellow flower, but the whole of it is densely and richly spotted with scarlet. Other very fine Cannas shown by Messrs. Paul were William Tolfts, Senateur A. Saunier, and Madame St. Dreer. In addition to the group of Cannas, Messrs. Paul had a few hardy flowers, including very fine inflorescences of *Thalictrum aquilegifolium rubrum* and album, and they were recommended an Award of Merit for *Mecanopsis cambrica plena* (double Welsh Poppy), figured in *Gardeners' Chronicle*, May 30, 1896, p. 671.

Sir TREVOR LAWRENCE, Bart., Burford, Dorking (gr., Mr. Bain), showed some interesting hardy flowers, including *Heuchera* labelled *leuzoides*, *Lychnis Viscaria alba*, *Pentstemon ovatus*, *Omphalodes linifolia*, with greyish foliage, and pure white blossoms; *Hedysarum multijugum*, *Heuchera sanguinea alba*, and a very showy crimson Poppy named Duke of Teck.

Sprays of *Rhododendron* flowers and Roses from Messrs. WM. PAUL & SON, Waltham Cross, Herts, made a very gorgeous display of bloom. Numerous varieties of *Rhododendrons* were shown as bright vigorous clusters of blooms, and we were informed that the plants grow in the ordinary staple loam of the Loughton (Essex) Nursery. The garden Roses included seedlings of the Scotch Briar, a dense habited, very free-blooming Rose, and varieties of the Sweet Briar (Silver Banksian Medal).

A grand display of Chinese *Pæonies*, *Pyrethrums*, &c., came from Messrs. KELWAY & SON, Langport, Somerset. The blooms, without exception, were very large, of great substance, and fine colour. It was difficult to ascertain the names of the varieties, owing to the smallness of the white tickets bearing them, and which were for the most part hidden among the foliage. It goes without saying, however, that these were of the very choicest. One of these, named Ella Christine, a large globular flower, of faint blush, and very fine, was recommended an Award of Merit. Other noticeable ones were Mrs. Stubbs, pink and white; Admiral Dewey, and Marchioness of Lansdowne. An Award of Merit

was also recommended to *Pyrethrum* Lady Kildare, and the group was awarded a Silver Flora Medal.

Messrs. VEITCH & SONS, of Chelsea, exhibited some choice *Gloxinias*, in small groups of several varieties. An Award of Merit was made to *Galatea*, a white flower marked with lilac. *Trilby*, a purple flower much spotted; *Seraph*, scarlet with white throat; *Virginalis*, pure white, and *Empress of India*, intense crimson, were all pretty. An Award of Merit was also recommended to *Philadelphus coronarius* var. *Mont Blanc*, a very free and precocious flowering pure white variety; sprays of *Cytisus Scoparius* var. *pallida* were also shown by Messrs. VEITCH. There were also sprays of flowering shrubs, including *Cornus Kousa* (*Benthamia japonica*), *Hydrangea hortensis mandschurica*, *Hibiscus cælestis*, a pretty blue single flowered species, *Hydrangea japonica Mariessii*, &c. They also put up a big semicircular group of hardy plants in flower at the end of the hall. These included masses of *Heuchera sanguinea*, of double-flowered *Pyrethrum roseum*, among which we note the old and still unsurpassed M. Barral, Aphrodite, Mrs. Dix, and Model, all good and distinct in tints, and possessing very double flowers. There were *Iris xiphium* in great variety, *Eremurus himalaicus* and *E. robustus*, numerous cut blooms of *Aquilegia hybrida*, the not over-plentiful white-flowered Iceland Poppy, *Saxifraga nepalensis* and others, and *Verbascum olympicum*.

The Hon. MARSHAM TOWNSEND, Frogna, showed a few Carnations.

Mr. FRED. PERKINS, nurseryman, Regent Street, Leamington, showed a number of plants of *Carnation Primrose Queen*, a scentless variety, of a nice lemon or primrose-yellow shade.

Messrs. BARR & SONS, King Street, Covent Garden, and Long Ditton, Surrey, exhibited a very comprehensive collection of tuberous and other species of *Iris* in great variety, inclusive of Spanish and English types; *Iris spuria*, *I. pallida*, *I. Lorteti*, &c. Other cut flowers consisted of *Muscari plumosum cristatum*, stronger than the type, and with longer flower-spikes; *Verbascum phoeniceum*, in several varieties; *Pink Lizzie Duval*, white, with fringed petals; *Brodiaea ixioideis*, double-flowered *Anemone la Dame Blanche*, white; also *A. Snowball*, of a greenish-white colour, and also double; *Calochortus Mawianus*, white with a purplish haze or shade at bottom of the flower; new varieties of *Dodecatheon*, *Scillas*, *Geranium Manescavi*; *Campanula glomerata*, *Camassia grandiflora*, *Hemerocallis Dumortieri*, a flower of a rich yellow or orange-colour, *Pyrethrum roseum* varieties, *Poppies*, &c. (Silver gilt Banksian Medal.)

Mr. JOHN RUSSELL, nurseryman, Richmond, Surrey, filled a long cross-table with cut blooms of hardy plants, set up in green bottles. We remarked numbers of *Iris*, *Pæonies*, *Hemerocallis*, *Papavers*, *Pyrethrum roseum*, *Heuchera*, *Veronica*, *Senecio*, *Allium roseum*, *Delphiniums*, *Ixias* (many), *Cypripedium calceolus*, &c.

A Japanese Maple, said to be fifteen years old, growing in a small china trough, was shown by Miss HANKEY, 123, Cambridge Street, W. In hard wood the plant was about 2 feet high, and it was brought from Japan last year.

From Mr. S. C. WHITFIELD, Eastbourne, was shown a variety of Ivy-leaved *Pelargonium*, named *Pride of Mount Sherborne*; and flowering sprays of *Bignonia Lindleyana* were contributed by Lady C. PLOWDEN, Aston Bowant House, Tetworth.

Some paintings and sketches of flowers and fruits, from Miss S. PUTMAN, 13, Craven Park Road, Harlesdon, N.W., were of considerable merit.

A bright scarlet-flowered zonal *Pelargonium*, from Messrs. W. & J. BROWN, Stamford, and named John French, appeared to be a useful one for bedding purposes.

Messrs. WALLACE & CO., Kilnfield Gardens, Colchester, made a gay exhibit of hardy bulbous flowers, including several of the earlier-flowering *Calochorti*. A First-class Certificate was awarded to one of these species named *C. Purdyi*. The flowers are about 9 inches or more high, rather small, silvery-white in colour, with light purple in the interior base; the petals are quite covered with soft downy hairs—a very pretty flower. We noticed also flowers of *C. pulchellus*, *C. Lyoni*, *C. Lorteti*, *Iris xiphium* in numerous varieties made a pretty show, and even more effective were the many varieties of *Iris germanica pallida*, of which Mrs. Darwin, a delicate flower containing much white, was very pretty. The charming little *I. pavonia* was also present, and fine flowers of *Anthericum liliastrium major*, the pretty and new *Lilium rubellum* (figured in a recent issue), &c. (Silver Banksian Medal).

Messrs. F. SANDER & CO., St. Albans, exhibited a group of new plants, including the *Acalyphas Sanderi* and *Godseffiana*. A First-class Certificate was awarded to *Mikania* (?) *Sanderi*, of which a plant over 3 feet in height was shown. The leaves are ovate acuminate, and green with velvety purple spots in colour; the midribs and stems reddish. *Caladium* Lord Annesley, with narrow acuminate leaves, centre red, with green border, the margins much crimped, was recommended an Award of Merit, and a like distinction was conferred upon an ornamental-leaved *Begonia* named Mrs. F. Sander. These handsome leaves had a green border, next silvery-red, and in centre a panel of deep brown colour.

Messrs. F. MILLER & CO., 267, Fulham Road, London, made a group of single-flowered *Petunias*, and *Mignonette* in pots; and Messrs. J. CHEAL & SONS, Lowfield Nursery, Crawley, had sprays of ornamental trees and shrubs.

From MARTIN R. SMITH, Esq., Warren House, Hayes Common (gr., Mr. Blick), were shown plants of *Carnation* Lady Hermione and Baldwin; the former is almost cherry-red in colour, and apparently a useful border variety; Baldwin is a rich pink-coloured variety of the Malmaison type.

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshaw, R. Brooman-White, H. M. Pollett, H. Little, A. H. Smee, H. J. Chapman, W. H. Young, E. Hill, T. W. Bond, C. Winn, W. Cobb, Ed. Handlay, S. Courtauld, J. G. Fowler, J. Douglas, and J. Gabriel.

There was a very interesting show of Orchids, the species being represented by many fine varieties, and the hybrids were more than usually numerous and good.

Sir TREVOR LAWRENCE, Bart., Burford, Dorking (gr., Mr. W. H. White), showed a neat group, in which were a fine example of *Dendrobium Bensoniae*, with thirty-nine flowers on one bulb (Cultural Commendation). The singular feather-lipped *Bulbophyllum saltatorium* (Botanical Certificate); the pretty *Bulbophyllum Lobbi* "Burford variety," with markings of rose-purple instead of the usual brownish colour (Botanical Certificate); *Odontoglossum* × *elegantius* "Burford variety," a very finely-coloured form of the pretty natural hybrid (Award of Merit); the white and yellow *Geodorum Augusti*, *Dendrobium polyphlebium*, a fine *Phalenopsis Aphrodite*, *Disa* × *kewensis*, *Odontoglossum crispum*, &c.

Sir FREDERICK WIGAN, Clare Lawn, East Sheen (gr., Mr. W. H. Young), staged an effective group, in which were the pretty *Lælio-Cattleya* × *Lady Wigan*, with large bluish-white flowers, delicately marked with purple on the lip; *L.-C.* × *superbo-elegans*, with rose-purple flowers; *L.-C.* × *Arnokiana*, *L.-C.* × *Canhamiana* *Iolanthe*, *Cattleya Mossiae maxima*, *Miltonia vexillaria* *Constance Wigan*, with very large, nearly white flowers; *Cymbidium tigrinum*, and a grand plant of *Scuticaria Hadweni*, with seven very fine flowers (Award of Merit).

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, were awarded a Silver Flora Medal for a group replete with fine hybrid Orchids. Of these were the magnificent *Lælio-Cattleya* × *Eudora splendens* (*C. Mendeli* × *L. purpurata*), with gorgeously tinted flowers of great size (First-class Certificate); *L.-C.* × *Canhamiana superba*, equally fine in colour, and the handsomest of its class (Award of Merit); *L.-C.* × *Hippolyta aurantiaca*, a charming clear yellow variation of the type, with a few purple lines on the lip (Award of Merit), and *Epi-Cattleya* × *radiato-Bowringiana* (*Ep. radiatum* × *C. Bowringiana*), a very remarkable hybrid of the habit of *E. fragrans* or *radiatum*, but with rose-purple flowers, approaching in form those of *C. Bowringiana* (Award of Merit). Other noteworthy things in Messrs. VEITCH's group were varieties of *L.-C.* × *Hippolyta* varying much in colour, *L.-C.* × *Eudora alba*, a fine plant of *Euphrontis* × *Veitchii*, with nine spikes; the orange-scarlet *Epidendrum* × *radico-vitellinum*, *Cattleya Mossiae Reinckiana*, and other *Cattleyas*, *C.* × *Enone* (*Mossiae* × *labiata*), *Disa* × *Veitchii*, *D.* × *Langleyensis*, *Cattleya* × *Gertrude* (*Mossiae* ♂, *superba* ♀), *Trichopilia suavis alba*, &c.

Mr. Jas. Hudson, gr. to Messrs. ROTHSCHILD, Gunnersbury House, was awarded a Silver Banksian Medal as a mark of good culture for a noble plant of *Lælia purpurata*, with thirty-three flowers. It is a portion of a plant purchased by Mr. Hudson's father in 1861.

Messrs. STANLEY, MOBBS & ASHTON, Southgate, were awarded a Silver Floral Medal for a fine group, in which the varieties of *Cattleya Mossiae* were remarkable; among them were *C. M. Sir T. Lipton*, a pure white, with a slight pink tinge on the lip; *C. M. Lieutenant Hobson*, a very large and richly-coloured flower; *C. M. Exquisita*, a dark-coloured flower, with purple line on the petals; and *C. M. Southgate* var.; and the charming *Reinckiana Madonna*, a fine white, with slight purple marking on the lip (Award of Merit). In the same group were *Cypripedium* × *Sir T. Lipton* (*bellatulum album* × *ciliolare*), with cream-white flower, bearing a few purple spots; *Lælia purpurata* Southgate variety, and other fine forms; *Cypripedium* × *Donald Ross*; various *Odontoglossums*, &c.

Messrs. F. SANDER & CO., St. Albans, showed *Lælio-Cattleya* × *Duke of York* (*L.-C. elegans* × *C.* × *Brymeriana*), a handsome hybrid, with rose flowers (First-class Certificate); *L. C.* × *Lily Measures*, a pretty hybrid; and *Sobra* × *Amesiae*, with large cream-white rose-tinted flowers; *S.* × *Veitchii*, *S. xantholeuca alba*, and *Thunia* × *Veitchii*.

R. I. MEASURES, Esq., Camberwell (gr., Mr. H. J. Chapman), showed *Lælia purpurata Ernestii*, a pretty flower, with pale yellow shade of white, and pale rose disc to the lip (Award of Merit).

Messrs. HUGH LOW & CO., Bush Hill Park, showed *Odontoglossum crispum* "Prince of Wales," a nobly grown plant, bearing the finest inflorescence and largest flowers ever produced by the best white form of the species—a grand variety and a magnificent plant (First-Class Certificate and Cultural Commendation).

Messrs. LINDEN, l'Horticulture Internationale, Parc Leopold, Brussels, showed *Odontoglossum crispum* *Le Czar*, a fine flower, with large blotch on the sepals; *O. c. Morning Star*, spotted and tinged with rose in a very peculiar manner; and *O. c. d'Allemagne*, a finely blotched form.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr., Mr. S. Cooke), showed *Lælia purpurata* (Mrs. De B. Crawshaw), a distinct white flower with violet-purple markings.

H. DRUCE, Esq., Circus Road, St. John's Wood, showed hybrids of *Cypripedium bellatulum*, &c.

Mr. JAS. O'BRIEN, Harrow-on-the-Hill, showed *Masdevallia angulata* (Botanical Certificate), a fleshy, purple and yellow flower of the *M. Gargantua* class.

Mr. JAS. McBEAN, Cooksbridge, showed a group of *Odontoglossum crispum*, some rose-tinted varieties, others finely spiked.

A. H. MILTON, Esq., Clifton, showed a finely flowered *Cattleya Mossiae*.

G. H. BIRD, Esq., West Wickham (gr., Mr. Reddan), sent *Odontoglossum crispum Romnyanum*.

Mrs. WINGFIELD, Ampthill (gr., Mr. Empson), showed *Cattleya Mossiae Wingfieldorum*, with curiously splashed flowers.

ARTHUR HAY, Esq., sent a fine *Cattleya Warszewiczii*; and Mr. J. W. MOORE, Eldon Place Nursery, Bradford, showed the singular *Vanda primula* with white flowers and purple lines on the lip, in the way of *V. cristata*.

Fruit Committee.

Present: Philip Crowley, Esq., chairman; and Messrs. T. F. Rivers, J. Willard, J. Cheal, A. F. Barron, J. Wright, A. Dean, G. T. Miles, Geo. Woodward, G. Wythes, H. Balderson, J. Smith, F. Q. Lane, G. Norman, and R. Fife.

An Award of Merit was recommended to a seedling Cucumber, The Keeper, fruits of which were shown by Mr. S. MORTIMER, Rowledge Nurseries, Farnham Royal. It is the progeny of a cross between Improved Telegraph and Duke of Edinburgh, and the fruits are rather long, deep green in colour, slightly rough, and spined, and altogether of distinct and good appearance. Mr. MORTIMER also showed excellent fruits of Sensation Cucumber, a variety distinguished by an Award of Merit in 1896.

A Cultural Commendation was awarded to Mr. J. Hudson, gr. to LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton, or a box of sixteen ripe fruits of Lord Napier Nectarine, gathered from a tree bearing a crop of 450 fruits. Mr. Hudson had also dishes of Annonay Cherries from a south wall in the open.

Mr. E. Beckett, gr. to Lord ALDENHAM, Aldenham House, Elstree, exhibited a fine broad-leaved Spinach, named The Carter, and a Cultural Commendation was deservedly given.

A variety of Cabbage, named Beaconsfield, shown by Mr. J. PROWSE, Hallbound Gardens, Beaconsfield, was recommended for an Award of Merit.

Mr. W. J. Empson, gr. to Mrs. WINGFIELD, Ampthill House, Ampthill, obtained an Award of Merit for a seedling Melon, a cross between Anthony's Favourite and Eastnor Castle. The seedling is a white-fleshed fruit of good flavour.

Lecture on Hybrid Orchids.

IN the afternoon, Dr. MASTERS, F.R.S., who occupied the chair, proceeded to read the names of the candidates for Fellowship of the Society, there being as many as 108 names—probably a larger number than has been submitted at any previous meeting of the Society. When these candidates had been duly elected, Mr. O'BRIEN commenced a paper on "Hybrid Orchids" by referring to a previous lecture upon hybrid Orchids, given by Mr. HARRY VEITCH and Mr. C. C. HURST before meetings of the Royal Horticultural Society, and since published in the Society's journal. Mr. O'Brien therefore preferred to treat the subject entirely from the standpoint of culture. Speaking of the value of the garden hybrids, it was claimed that the hybridist had raised a large number of showy kinds that bloom at all seasons of the year. In this latter particular, garden hybrids had an advantage over natural ones, because species of Orchids that are cross-fertilised in their native habitats are necessarily pollinated by species that are in flower at the same season of the year. The hybridist on the other hand, by reason of the artificial conditions of Orchid-culture inducing many plants to bloom out of their proper season, was enabled to cross his plant with another one that naturally blossoms at another period of the year. Thus, in addition to new tints of colour, and modifications in form, the hybridist does obtain plants that bloom between seasons—a very decided advantage. The hybrid may generally be expected to bloom at about the mid-season of blooming of the seed-bearing plant.

But good though the general effect of hybridisation has been, the practice has not proved an unmixed blessing. In *Cypripediums*, for instance, many of the hybrids that have been raised and put into commerce can only be described as "weeds" of the type they represent, and Mr. O'Brien very properly declared that the Orchid cross-breeder should exercise the greatest care in selecting seedlings for distribution, and should, after taking full notes, and, if possible, drawings, be content to destroy all seedlings of inferior characteristics in the same way as is done by raisers of florists' flowers generally.

Passing to the theory of insect-fertilisation of Orchids, Mr. O'Brien said that observers in the tropics had generally little faith in this theory in the early stages of their observation; but the lecturer believed that though Nature provided the plants with means for self-fertilisation it was only as a last resource. Observers had noticed that the seed-capsules had swelled where there had been no possibility of insect intrusion, and had been thereby misled. Mr. O'Brien said that in most cases he believed that there was no good seed in such capsules, but they had swelled owing to the stigmatic surface having been irritated by dust, grit, or other foreign substance. He referred to an experiment he had made with an *Odontoglossum* and with other Orchids, when, after having irritated the stigmatic surface by brushing, the capsules had swelled normally, but they contained no perfect seed.

Passing to the actual work of hybridising, Mr. O'Brien said that of the seed sown there was a larger proportion of plants raised by the hybridist than occurred naturally, when from many causes which he specified the waste of seed was enormous. Orchid raisers had two disadvantages—they frequently sowed seeds which the lecturer believed were not capable of germination, and there were our long, sunless, foggy winters. Though the hybridist had been successful

with very many species, there were some which resisted every attempt of his. *Laelia Digbyana*, for instance, yields no seeds itself, and cannot be hybridised. The seed capsules of Orchids, when they become heavy, should be suspended with pieces of tape, so that the circulation of sap may not be hindered by the stalk becoming bent. The capsules of Orchids grown in a glass-house do not split at so early a period as occurs naturally, and it is thought that the seeds are often ripe before dehiscence takes place. The seeds should therefore be sown at once, at whatever season they ripen, as the risk of retaining them would be greater than that attending the sowing of them, even in winter.

In the matter of sowing the seeds, Mr. O'Brien quoted some remarks of Mr. Jno. Seden, to the effect that although he had tried many methods he had yet discovered none that had greater advantages than that of sowing the seeds upon the surface of the potting material in which a healthy plant of the species was growing. A plant that was suspended, or at least one that was somewhat near to the glass, should be selected for this purpose. The compost should be sweet, and if covered with growing sphagnum moss, this should be cut back. The seeds should then be sown thinly over the surface, and the greatest care afterwards exercised in the matter of watering, that the seeds be not washed away or even disturbed.

A fruitful cause of failure was the growth of moss or other low vegetable life over the surface of the compost, and this was more troublesome when fresh material had been used. Sterilisation of compost was therefore desirable, and it should be done with boiling water rather than by baking. As soon as it could possibly be done, the seedling plants should be pricked off into a sterilised compost, and placed early into tiny pots singly. Ventilation, especially in spring, needed great care. The opening of top ventilators had, he believed, killed many valuable plants. On cold days it was much better to keep the top ventilators closed, or nearly so, and thus create less occasion for firing. Mr. O'Brien thought a 1-foot swing ventilator at either end at the top of the house was sufficient.

Mr. C. C. HURST, in referring to the instances of seed-capsule formation in the absence of pollination, cited by Mr. O'Brien, described them as very remarkable.

Mr. DE B. CRAWSHAY said that he had a fine plant of *Cymbidium Lowianum* which annually produced a spike of more than twenty flowers. Each year from every flower there was produced a capsule. Was it possible that an insect traversed every flower each year? He thought not. The capsules fell away in about five or six weeks.

After some remarks by Mr. R. A. ROLFE upon the general question of Orchid hybridisation,

Dr. MASTERS also referred to the question of capsule-swelling from irritation. He thought the circumstance would not appear so marvellous if they remembered that the capsule was part of the mother-plant; and in cases such as were mentioned, there had been not the least effect made upon the seeds or rather upon the ovules. Such phenomena were common in many other very different plants. Some species of *Passifloras* had been found incapable of fertilisation by their own pollen; they invariably required pollen from another species.

LINNEAN.

JUNE 2.—At the last meeting of the Society on the above date (Mr. ALBERT D. MICHAEL, Vice-President, in the Chair), Messrs. Edward Charles Horrell and George Nicholson were admitted, and Mr. Eugène Frederick Augustus Obach was elected a Fellow. The Chairman announced that the President had nominated Messrs. William Carruthers, Frank Crisp, Albert D. Michael, and Dr. H. D. Scott, to be Vice-Presidents for the ensuing year.

Mr. E. Salmon read a paper entitled "A Revision of the Genus *Symblypharis*." This genus of mosses, he said, as founded by Montagne in 1839, had proved too narrow, through the limits imposed by certain peristome characters, and he was of opinion that Mitten's later amended description should be accepted. Montagne had founded the genus for the Mexican *S. helicophylla*, and to this species Mr. Salmon would refer the Indian moss, *S. himalayana*, Mitten (*Didymodon vaginatum*, Hook.), as well as *S. Chrismani*, C. Müll., and *S. asiatica*, Besch., which were found not to possess the characters by which they had been separated from *S. helicophylla*, Mont. *S. microcarpa*, C. Müll., he considered to be a variety of *S. helicophylla*, Mont.; and two new varieties of that species were described—*vars. tenuis* and *macrospora*—the latter remarkable for its large spores, 35–45 μ . In the course of his remarks on other species of the genus, Mr. Salmon observed that *S. fragilis*, Mitt., is peculiar in the bistratose structure of the leaf, and *S. socotrana*, Mitt. (doubtfully included in the genus in the absence of fruit), in the papillose-cells. *S. circinata*, Besch., and *S. usambarica*, Broth., he would exclude from the genus, and pointed out that the former species, from Grande Comore and La Réunion, comprises two distinct mosses. Mr. Charles Henry Wright, A.L.S., offered some critical remarks.

Surgeon-Captain Cummins, F.L.S., read a paper "On the Food of the Uropoda." The nature of the food of these mites, which belong to a highly-specialised genus of the Gamasinae, has long been a puzzle even to those who have paid particular attention to their organisation. From careful experiments and observation, the author of the paper had come to the conclusion that amongst the organisms on which the Uropoda live were many species of bacilli, including the *Potato-bacillus* and the *earth-bacillus*. Yeast-cells were rapidly devoured, as also were Micrococci. He had little doubt that they consumed the gonidia of fungi, for species of

Penicillium and *Mucor* never appeared in the boxes which contained mites in large numbers; otherwise they were commonly present. Mr. A. D. Michael, in criticising the paper, pointed out the distinguishing characters of the Uropoda as compared with others of the Gamasinae, and especially the peculiar form of the mandibles, which suggested a different mode of feeding to that adopted by other mites. He considered Surgeon-Captain Cummins' observations on the subject a useful contribution to knowledge.

Mr. C. B. Clarke, F.R.S., F.L.S., gave a summary of a paper "On the Subdivision of Biological Areas in India," and in the course of his remarks mentioned some interesting facts in connection with plant-distribution in the Indian Oriental region. Dr. Otto Stapf, A.L.S., in commenting on the paper, expressed the opinion that the limits of the subdivisions proposed were natural, and might well be accepted by botanists.

HORTICULTURE AT THE ROYAL CORNWALL AGRICULTURAL SHOW.

JUNE 8.—This show, held at Penzance on the above date, was favoured both by the beautiful weather and the magnificent view of Mount's Bay obtained from the grounds. Of course, gardening does not usually receive very much space or attention at a show of the nature of the Royal Cornwall, still, the tent devoted to it was the largest on the ground, being over 200 feet long.

The most interesting exhibits were those not for competition. The competitors for prizes were very few in number, and their exhibits mostly not of a high standard. I scarcely a single class were there more than two entries, and in many cases one exhibitor had a class to himself.

The prizes for stove and greenhouse plants were chiefly won by Mr. W. Madge, gr. to E. HAIN, Esq., St. Ives; Mr. C. Brann gr. to J. BRANWELL, Esq., Beryain; Mr. John Roberts gr. to Mrs. HENRY, Tredanah, Penzance; Mr. Gill, gr. to P. T. CHIRWIN, Esq., Paul; and Mr. King, gr. to W. BICKFORD SMITH, Esq., Trevanno. Among the cut flowers there was little of interest.

Classes 43, 44, and 45, devoted to Roses, were without entries, and the same held good of Class 34, devoted to Carnations and Picotees. Rev. R. W. AITKIN, of Paul, took most of the prizes for Pansies, including a Silver Medal for the best Pansy in the Show (Col. M. R. G. Buchanan being the variety shown). The bouquets, sprays, and arrangements of cut-flowers for table decoration, showed little taste, though the flowers used (largely Irises) lent every facility for the production of graceful effect.

The fruits and vegetables were of a much higher order than the flowers. The exhibits of Mr. George Rowe, gr. to Rev. Canon HOCKIN, of Hayle, were especially good. Mr. SCOBLE, of Malpas, and Mr. F. CRAYE, of Lelant, also showed excellent fruit and vegetables, and divided the prizes left to Mr. Rowe.

Among the nurserymen's exhibits, many interesting plants, including some well-grown Tea Roses, were shown by Messrs. VEITCH of Exeter, JARMAN of Chard, and Messrs. Hodge of St. Austell.

The total effect of the show, however, can hardly be considered as important in its mirroring of or action on Cornish horticulture.

THE GRAND YORKSHIRE GALA AT YORK.

JUNE 15, 16, 17.—In pleasing contrast to the last opening day of this Show, the morning broke bright and fine, and the possibility of a recurrence of last year's disaster seemed very remote. The exhibits, thanks, no doubt, to the liberal treatment of the unfortunate exhibitors last year, were equal in number and quality to those of any previous shows, with few exceptions.

On entering the first tent one was at once attracted by the very interesting exhibit of Messrs. SUTTON & SONS, of Reading, which included select strains of *Gloxinias*, also samples of Tomatoes, fruiting in pots, and Peas in pots bearing a good number of pods. This exhibit was quite one of the features of the Show.

On the right of the first tent Messrs. FISHER, SON & SIBRA, nurserymen, Sheffield, staged a large representative collection of *Rhododendron* hybridum in bloom, arranged in the form of a bank; also from the same firm was staged a choice collection of Japanese Acers, tree Ivies, &c., besides *Croton*, *Dracenas*, and other indoor plants, the whole forming an attractive exhibit. Following these was a magnificent group of *Caladiums* and *Begonias* from Messrs. PEED, of Norwood. Messrs. JAS. VEITCH & SONS, Ltd., also staged in the same tent a charming group containing some grand specimens of *Caladiums*, Tree Carnations, *Dracenas*, *Streptocarpus* of their raising, also a pretty little lot of *Rhododendrons japonicum* and *jasmiflorum*.

Messrs. CUTBUSH & SON, showed a most interesting group of *Carnation de la Malmaison* varieties, of *Ericas*, of *Turner's Crimson Rambler Rose*, and other plants, the whole being arranged with much good taste; and more especially noticeable was a batch of Carnations, Princess of Wales.

Messrs. R. SMITH & Co., Worcester, exhibited a nice lot of *Clematis*, trained, and these were interspersed with cut specimens of herbaceous plants and *Bambusa gracilis*.

On the centre stage was grouped the usual fine display of

specimen greenhouse and stove plants, the leading exhibitor in this class being Mr. J. CYPHER, nurseryman, of Cheltenham; the Marquis of ZETLAND, Aske Hall (gr., Mr. G. H. Letts); H. HARRISON BROADLEY, Esq., Welter House, Brough (gr., Mr. C. Lawton); Mrs. G. PEASE, Woodside, Darlington (gr., Mr. J. McIntyre).

The Orchids were especially fine, and the finest group in this class, not in competition, was that from the nurseries of Messrs. HUGH LOW & CO., Clapton, London, N. This group contained grand specimens of *Cattleya Mossiae*, *Lælia purpurata*, &c.

Messrs. SANDER & CO., nurserymen, St. Albans, also exhibited a batch of their new *Acalypha Sanderi* in their group.

The groups of plants, always a feature at this northern show, were as usual up to the standard of excellence. The premier honours of the year went to Mr. MEE of Nottingham, whose exhibits contained grand *Crotons*, also a choice lot of *Odontoglossum crispum*; and the 2nd prize went to Sir JAMES RECKETT, Bart., Swanland Manor, Brough (gr., Mr. George Wilson). This last-named group was most artistically arranged. The miniature cascade and Water-Lilies were the chief new features in it. The other groups, without exception, were likewise meritorious.

The groups of Orchids were fine. In specimen Orchids the premier Awards went to Mr. J. CYPHER of Cheltenham, and other good exhibits came from E. B. FABER, Esq., Harrogate; W. B. BURKENSCHAW, Esq., Hessele; JOHN ROBSON, Esq., T. STATTER, Esq., and J. E. WATERHOUSE, Esq.

Messrs. CLABAN of Altrincham showed a grand bank of cut flowers of herbaceous plants in great variety.

The Pelargoniums, always a feature here, were this year quite up to the usual standard of excellence. Mrs. TERLEY, of Leeds (gr., Mr. J. Eastwood), and J. T. HINGSTON, Esq. (gr., Mr. McIntosh), as usual, being keen competitors in the chief classes. In the class for twelve show varieties Mr. MCINTOSH was 1st. Other exhibitors of Pelargoniums and zonals were Messrs. H. PYBUS, R. SIMPSON & SON, Selby; and Miss WHARTON.

J. T. HINGSTON, Esq., was 1st for six specimen Fuchsias, Mrs. TERLEY 2nd, and Miss WHARTON 3rd. All of these exhibits were good ones.

The Roses were not especially good, and the 1st prize for seventy-two was taken by Messrs. J. & A. MAY, nurserymen, Bedale. Mr. GEO. MOUNT, nurserymen, of Canterbury, also exhibited.

In the groups of Carnations, Lord BARNARD was 1st, with a nice lot of *Souvenir de la Malmaison*.

Messrs. PERKINS, of Coventry, and Messrs. WEBSTER, of Sunderland, were the chief exhibitors of bouquets and floral devices, Messrs. PERKINS & SON taking the 1st prize in each section.

Herbaceous cut flowers were shown in great variety, and of very excellent quality—better than was expected.

Mr. G. YELD, of Clifton Cottage, exhibited some pleasing *Hemrocallis*, *Iris*, &c., of his own raising.

MISS LITTLE & BALLANTYNE, Carlisle, included in their exhibit the Golden Holly, named Golden King, shown at the Temple, and this was awarded a First-class Certificate.

In table-plants, Mr. J. C. MEE was 1st; E. B. FABER, Esq., 3rd.

FRUITS.

The chief features on entering the fruit-tent were the tables of fruit, for which there were four entries, the 1st prize went to Lord BARNARD (gr., Mr. Tullett); the 2nd prize was awarded to Earl of HARRINGTON (gr., Mr. Goodacre); the 3rd going to Sir JOS. PEASE, Bt. (gr., Mr. McIntosh). The awarding of the 2nd prize seemed to be the cause of some comment.

The fruit generally was very fine for this time of the year, and the chief prizes in the various classes were taken by Sir JOS. PEASE, Bt., the Earl of HARRINGTON, Lord H. OSWALD, &c.

MARKETS.

COVENT GARDEN, JUNE 16.

FRUIT.—AVERAGE WHOLESALE PRICES.

Strawberries, per lb. ...	2 0 4 0
— 2nd quality ...	1 0 2 0
— Southampton, baskets ...	6 0 10 0

REMARKS.—It is said that the Tasmanian Apples now on sale are the last of the season. Of Apricots, but few can be described as good. Bananas are easier in price. Gooseberries plentiful. Pine-apples appear to be getting towards the end of their season. Strawberries are coming in various packages, and from various sources. Southampton have commenced, but sunshine to colour them is lacking. Foreign Asparagus is nearly over, and only the very large sticks are worth sending. Vegetable-marrows may be daily expected to get cheaper, also Peas; and a few days of sunshine will bring them on rapidly, and put some corn in them.

POTATOS.

Fairly large supplies of New Potatoes; trade steady at following rates:—Jersey New Potatoes, 8s. to 8s. 6d.; Chesham and St. Malo, 7s. to 7s. 6d.; Canary Kidneys, 8s. to 8s. 6d.; Lisibon Rounds, 6s. to 7s. per cwt.; Old Potatoes, 100s. to 150s. per ton. John Bath, 32 and 34, Wellington Street, Covent Garden.

SEEDS.

LONDON: June 15.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that there were but few buyers on to-day's seed market, and the business doing was on a very restricted scale. Clover seeds just now are quite neglected. For Mustard and Rape seed full prices are asked. There is no change in Canary seed, but Hemp seed attracts increased attention. The sale for Peas and Haricots is slow on former terms.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending June 11, and for the corresponding period of 1897, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1897.	1898.	Difference.
s. d.	s. d.	s. d.	s. d.
Wheat ...	27 4	45 4	+ 18 0
Barley ...	22 8	25 8	+ 3 0
Oats ...	17 11	20 11	+ 3 0

(Remainder of Markets carried forward to p. ix.)

[The term "accumulated temperature" indicates the aggregate amount, as well as the duration, of degrees of temperature above or below 42° Fahr. for the period named: and this combined result is expressed in Day-degrees—a "Day-degree" signifying 1° continued for twenty-four hours, or any other number of degrees for an inversely proportional number of hours.]

0, Scotland, N. Principal Wheat-producing Districts—1, Scotland, E.; 2, England, N.E.; 3, England, E.; 4, Midland Counties; 5, England, including London, S. Principal Grazing, &c., Districts—6, Scotland, W.; 7, England, N.W.; 8, England, S.W.; 9, Ireland, N.; 10, Ireland, S.; * Channel Islands.

NOTICES TO CORRESPONDENTS.

ASTER SEEDLINGS: *Wallis*. The seedlings sent show all the signs of damping-off. When received they were soft and rotten at the surface of the soil, while the roots and foliage looked healthy. The damping off fungus, *Phytophthora sempervivi*, was found, as well as other fungi, which generally accompany it and assist in killing plants. This opinion is further supported by your observation that both planted-out seedlings and those left in the seed-bed were equally diseased. An article in last week's *Gardeners' Chronicle* will probably give you the hints you require for prevention in future.

BLIGHT ON GRAPE VINES: *Claptonian*. The Vine is infested with mealy-bug. Pick them off by hand as far as possible, and touch the woolly masses with a camel-hair pencil dipped in methylated spirits.

BULBS, &c., INFESTED BY BULB-MITE: *G. A.* These are certainly suffering from Bulb-mite to an extensive extent. We will publish your communication shortly.

CARBOLIC ACID AND SEWAGE: *G. H.* A distinguished chemist says, that any addition of antiseptics to the soil arrests, if it does not altogether stop, the nitrification; or, put more simply, the conversion of ammonia into nitric acid by the instrumentality of microbes or bacteria. His authority for this is Professor Robert Warington, F.R.S. one of the leading authorities on matters connected with sewage and its disposal and utility. Carbon-bisulphide, recommended and used so successfully in the prevention and cure of Phylloxera in Vines chloroform, and other like compounds, have the same effect. It is doubtful if even the addition of lime or any other alkaline substance would restore the sewage to its primitive utility. *T. B.*

CARNATION: *T. H. S.* Your white-flowering seedling is pretty, and the habit of free-blooming in the measure you describe should make it a good border plant.

CARNATIONS DISEASED: *Henley*. The plants sent all show attack by the Carnation Rust (*Uromyces caryophyllinus*). The greyish blisters are the first stage, the brown spots on dead leaves are a later stage, in which the spores are given off. At present the spores produced are those which germinate at once, and rapidly spread the disease; a later form of spore survives the winter and propagates the fungus next season. Plants and shoots badly attacked should be cleared out at once. The disease has been proved to be kept in check by use of Bordeaux Mixture (see this paper of August, 1897), if the first spraying be made early. Sulphide of potassium, or liver of sulphur, $\frac{1}{2}$ oz. to each gallon of water, is also considered good. These are, however, checks to the disease, not true cures. You should be able to get suitable varieties, which will be more proof against this fungus. Many growers consider it advisable not to wet the foliage too much in watering; wet foliage and scanty ventilation aid the spread of the fungus.

CHRYSANTHEMUM FUNGUS: *W. C.* Yes; burn affected plants, and syringe the remainder with liver-of-sulphur 1 oz. to a gal. of water.

CORRECTIONS.—In answer to correspondents, p. 368, in our last issue, read sulphide of potassium instead of sulphate of potassium, &c., inadvertently printed; and in Mr. Fish's article on Asparagus, p. 367, for 472 lb., read 4½ lb.

CROTON: *J. P.* The leaves are wretchedly thin and poor. We cannot say definitely what has caused this, but it is purely a matter of cultivation. See that your practice is brought into as close agreement as possible with the general principles of stove-plant cultivation. When taking cuttings, or "ringing" top-growths, take care to select strong ones. Finally, beware of a too liberal use of chemical manures, and avoid checks to the growth of the plants from any cause.

DISEASED IRIS: *Clifton*. The disease is due to a leaf-spot fungus, probably *Helminthosporium gracile*, or some allied form. The elongated spots on green leaves become open cracks later, and give off greenish-brown spores. The disease begins on the young sheaths which become discoloured and die, hence the plants suffer from want of nourishment. The bulbs look quite healthy; spraying with Bordeaux Mixture (see *Gardeners' Chronicle* of last August), will probably keep the fungus in check, and allow the plants to develop in a healthy way.

EXUDATION OF SAP FROM SWEET-CHESTNUT TREES: *R. T.* The flow of sap will shortly cease, and no harm will be done. If the bark then heals over, all traces will be obliterated in a year or two by new growth of bark.

GLOXINIAS: *A. C.* The leaves sent are exceedingly large and luxuriant, the largest being 13 inches long by 8½ inches wide. We think we have seen Gloxinia leaves as large as this before, but do not remember whether the plants were two or more years old. After all, it may not be advisable to cultivate the plants so strongly, for thereby a certain degree of coarseness is obtained. However, as yours carry fifty to sixty flowers each, we should imagine them to be very handsome specimens.

HYDRANGEAS: *Anxious*. Green shoots taken off with a thin heel of last year's wood strike readily in bottom-heat of 80° in a frame. Half-ripened shoots furnished with flower-buds may be taken off at the third or fourth joint, and after being stripped of the last pair of leaves may be inserted singly in 60's, or to the number of six round a 6-inch pot. The cuttings strike well in sandy-loam if inserted firmly about 1½ inches deep, and afforded bottom-heat of 75°; but the tops must be kept cool, with the lights tilted night and day. Such plants if repotted when rooted, and once afterwards, kept in a sunny frame or pit well exposed to the sun, and treated generously as regards manure-water, syringing, and damping down, will make nice flowering plants by the middle of October. They must at that season be gradually brought to a state of rest by withholding water, and affording plenty of air; and during the winter the plants should be plunged in a bed of leaves in a cold pit or frame. They will throw good heads of bloom the next winter and spring if forced, and should not be repotted till blooming is past.

IRIS WITH FUNGUS: *Xiphium*. Your Irises are affected by a smut fungus. Spraying with Bordeaux Mixture in early spring might arrest, though it would not cure the malady.

LABURNUM OF DIFFERENT COLOURS: *R. M.* The variety with pink flowers is *Cytisus Adami*.

LIME-TREES: *X. Y. Z.* We do not suppose that anything you can do will preserve the lives of the trees amidst such unwholesome surroundings, and you had better advise the substitution of Poplar-trees, viz., Abele, black, white, and Canadian, and as a shrub that defies smoke, soot, and most kinds of fumes, the common Elder and its several yellow and white variegated forms. These trees and shrubs are found to succeed in the Leazes Park, Newcastle-on-Tyne, where the conditions are nearly similar to those you exist under.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*R. P.* A form of *Papaver Rhæas*, called Shirley Poppy. There are single and double-flowered varieties. — *Wm. W.* 1, *Phrynum variegatum*; 2, *Aërides crispum*; 3, *Chysis lævis*; 4, *Glechoma hederacea variegata* (variegated Ground Ivy); 5, *Festuca ovina glauca*; 6, one of the garden forms of *Pelargonium grossulariæfolium variegatum*. — *H. Eastlea*. *Agaricus* (*Pholiota*) *durus*, not uncommon. It is not edible. *M. C. C.*—*S. D.* *Muscari comosum monstrosum*. — *W. NERIUM OLEANDER: *Anxious*. Propagation is by means of cuttings of last year's shoots in spring and early summer. The plant roots as readily as a Willow in earth, sand, or water, with no more heat than that of a greenhouse. If you can layer a big piece into a flower-pot you will secure a flowering-plant in a twelvemonth. The layering may be done at the present season.

ODONTOGLOSSUM - HOUSE: *Amateur*. Wood would answer for the walls of such a temporary house as that you require; and in case of a very cold winter, you might protect the wooden walls with litter or earth. The second-hand hot-water pipes, if sound, may last many years longer.

PEACH LEAVES AND FRUITS: *T. S.* Very bad examples of mildew. Remove the worst of the leaves and all fruits that have the least sign of mildew on them, burning these forthwith. Having done this, syringe the trees with sulphide of potassium $\frac{1}{2}$ -oz. to a gallon of water, or use flowers-of-sulphur with a dredger. See answer to "Cymro" under Vines in this column.

POT-POURRI. *V. F. S.* This may consist of a variety of sweet-smelling flowers, roots, leaves, and seeds. We may mention Tonquin and Vanilla-beans, Orris-root, Orchis fusca, petals of fragrant varieties of the Rose, Sweet Verbena, Lemon-grass, Kus-kus (*Andropogon muricatus*), Patchouly, Lavender-flowers, Orange-flowers, ground Nutmegs, &c. The various substances should be dried in the shade, and stored in open jars, and frequently stirred to dissipate the odour.

QUICK OR WHITETHORN: *F. W.* Life is not long enough to wait till seedlings are raised, but you can buy Quicks very cheaply of some of the nurserymen. Buy as many as you require in October or November, laying them in on arrival; then proceed to stake out the line of the hedge. It is a good plan to trench and manure a space of 6 feet wide, and the length of the hedge, and reserve a space of 3 feet wide for the plants, the margin of soil for 1½ feet on either side of this plot, and one to two spits deep being thrown on to the central plot in order to add to its depth, and afford a slightly elevated platform for the hedge. Having made the

plot level, and trodden it firmly, stretch the line along the centre, and proceed to plant, first trimming the roots and slightly topping the plants. There are two methods of planting, i.e., against a vertical notch cut with a spade, by which all the roots are one side; and the other is, to take out a few spits at one end of the line and on both sides of it, putting the plants in at 6 inches apart, and almost touching the line, and working backwards. By this method the roots can be spread out in the holes, and they are not more numerous on one side than another, and the ground is not trodden upon after the filling in is done. Which-ever is adopted, two persons must work together, one trimming and holding the plants, and fastening them in the ground, whilst the other digs the holes and fills in. If you decide to have a ditch as a further defence against horned stock and horses, the dug out soil should be thrown partly or wholly on to the site of the hedge, then no other additional soil becomes necessary, and the trenched ground need not exceed 3 feet in total width. No virgin soil should be trenched deeper than two spits at first, nor should a greater thickness than 6 inches of inert, infertile subsoil be added on the top of the dug ground, otherwise the Quicks will make slow progress for some years. A Quickset hedge should always be protected by posts and rails until it is strong enough to resist encroachment from sheep and cattle.

TOMATOS: *W. Ross*. The fruits and leaves are affected by the "Spot" disease, *Cladosporium lycopersici*. There is no known cure, and you ought to clear and burn the plants.

TOMATO LEAVES: *W. Parker*. The "Sleepy Disease." See answer to J. Claydon in *Gardeners' Chronicle* for June 11.

VINES: *Cymro*. Mildew was found on the leaves, and it will be necessary to use sulphide of potassium $\frac{1}{2}$ -oz. or more to a gal. of water, or dust with flowers-of-sulphur, employing a mechanical sulphurator or dredger. Sulphur should be mixed to a thick paste with water, and then being slightly diluted may be placed in saucers about the vinery. The air in the vinery should be kept buoyant, not over moist, the heating apparatus being used in damp cool weather, ventilation being mostly afforded at the upper part of the vinery. That which mildew has settled upon remains disfigured; and mildewed Grapes, even when the fungus is killed, are spoiled, the affected part of the skin losing its power of expanding as the contents increase in bulk, with the consequences that the skin bursts, and decay sets in. It is better to remove and burn all mildewed berries at once.

VINE LEA IS BROWNED AND DISFIGURED: *Phœnix Newton*. The vinery has not been well attended in the matter of affording air, and the leaves are "scalded"—that is, by excessive heat and moisture combined, the leaves have become, as it were, scalded by water. Afford air earlier in the morning, a little at a time, till the greatest heat is passed, and then as gradually reduce the ventilation till at from 3.30 to 4 P.M. the house is closed. About 7 or 8 P.M. afford a small amount of ventilation at the top of the house. Remember Vines are hardy plants, and bear forcing only under certain conditions.

ZONAL PELARGONIUMS: *J. T. D.* The plants have collapsed in consequence of the stems having been buried too deeply, hindering the access of air to the green parts of the stems and the roots. It is deprivation of air and hindrance of transpiration, suffocation in fact, and the result is decay affecting the stem and shoots in certain parts, followed by death of the parts above them.

CONTINUED LARGE INCREASE in the CIRCULATION of the "GARDENERS' CHRONICLE."

Important to Advertisers.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper,

MORE THAN DOUBLED, and that it continues to increase weekly. Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, and ALL CLASSES OF GARDENERS and GARDEN-LOVERS at home, that it has a specially large FOREIGN and COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

THE

Gardeners' Chronicle.

SATURDAY, JUNE 25, 1898.

THE HISTORY OF THE RADISH.

IN the *Gardeners' Chronicle* for May 14, p. 296, some hesitation is expressed as to the garden Radish having arisen from *Raphanus Raphanistrum*, L., as M. E. A. Carrière seems to infer from his experiments (*Origine des Plantes domestiques, démontrée par la culture du Radis sauvage*). It is suggested that it may be derived from an Indian species, now perhaps extinct, from the consideration of the structure of the leaves and pods, those of *R. Raphanistrum* being jointed, while those of *R. sativus* are without partitions. Again, the petals of the former are often yellow, but those of the Radish are white or pink.

From the history of the Radish, as appears from Theophrastus downwards in European herbals, it would seem that it arose from *R. maritimus*, which Bentham regards as a Mediterranean variety of *Raphanus Raphanistrum*. This may account for the cultivated Radish "resisting cold less well than the wild variety," and hence the writer says, "we may infer that the former (the cultivated Radish) has a more southerly origin." Bentham's words are as follows:—"A sea-coast variety, particularly abundant round the Mediterranean, but extending up the shores of W. Europe to those of [Jersey] England, Ireland, and southern Scotland, has been distinguished as a species, under the name of *R. maritimus* (*Eng. Bot.*, t. 1643). It has the leaves usually more divided, the pods often longer (or 1—2 jointed, and sharp-pointed, *G. H.*), and is apt to last a second year; but all the other characters derived from the colour of the flower, the comparative length of the style and pod, the depth of the furrows, &c., occur also on inland specimens—at least on the Continent."

ANCIENT HISTORY.

The Radish was well known to the ancients. Pliny, writing in the first century, A.D., and quoting from Theophrastus (*Lib. vii.*, c. 4), refers to several varieties which were therefore grown about 370 B.C., both long and round-rooted. Of the "Syrian," he says, "it is pretty nearly the mildest and the most tender of all, and is well able to bear the winter; while "one brought from Syria lasts the whole of the winter through," apparently a different sort from the preceding. He then hints at different degrees of tenderness, the result of the different climates where they grew.

In addition to the cultivated, he refers to the wild or "agrian," which our people call "armoracia" (*lib. xix.*, c. 26). In Daubeney's *Roman Husbandry*, that author enumerates all the plants noticed by Dioscorides, and the cha-

acters of the drawing attached to the celebrated Vienna MS. of the fifth century. Of the Radish he says:—"Raphanis, *Raphanus sativus*, "good;" *R. agria*, *R. Raphanistrum*, "pretty good." Matthioli, in his *Commentary on Dioscorides* (pub. A.D. 1560), figures on p. 268 the Radish under *Raphanus* with a Carrot-like root. The siliques are only one to two-seeded, with a constriction between them, and terminating with a sharp point. Dioscorides himself says, "The wild Radish, *R. sylvestris*, the Romans called *Armoracia*, and leaves like those of the cultivated . . . and a slender root, tender and subacid."

Sixteenth Century Writers.—Besides Matthioli's *Commentary*, Dodoens, in his volumes of illustrations to his *Commentarium de Striptum Historia* (vol. ii., No. 142), figures *R. sativus* as having ovate-acuminate pods, with or without a constriction. The leaf is given as very strongly serrated. Gerarde (*Herbal*, A.D. 1597, pp. 183, 184) figures 1, *R. sativus*, with an oblong root and pods cylindrical without constrictions or pointed tips, and describes it as having "purple flowers." 2, a small Turnip-radish; no flowers or pods given. 3, *R. orbicularis*, and 4, *R. pyriformis*, both these having two seeded and constricted pods with pointed apices. The flowers of (3) are "purple," and of (4) "flesh-colour."

"The Wilde Radish," *R. sylvestris* (p. 185), has long pods with constrictions feebly represented, and the leaf is scarcely sufficiently lyrate to represent *R. Raphanistrum*. The flowers are yellow. It seems to represent *Nasturtium sylvestre*, Br.

Some confusion arose about this time, for Dodoens figures *R. sylvestris* as the Horse-Radish, i.e., Gerarde's *R. rusticanus*; while Gerarde's *R. aquaticus* or water-Radish is Dodoens' *R. palustris*, i.e., *Nasturtium palustre*, L.

Seventeenth Century.—Castore Durante in his *Herbarium*, 1636, A.D., figures *R. hortensis* with lyrate leaves, the margins of the segments being entire, the pods short, ovate, with sharp points without constrictions. *R. sylvestris*, *R. Agria* of the Greeks, and *Armoracia* of Latins, has similar pods, but the leaves are serrated. *R. hortensis* has white flowers; those of the wild plants are not mentioned. The drawings are not good.

Parkinson in his *Theatre of Plants* (1640, A.D.) figures a Carrot-like and a Turnip-rooted form. Both have short-pointed pods with a slight constriction. The one is called *R. vulgaris*, ordinary garden Reddish (a misnomer from the colour), and the other is *R. niger rotundior* radice, the rounder-rooted blacke Reddish.

The wild Radish he figures under *Rapistrum album articulatum*, white wilde Charlocke, with long articulated siliques. This appears therefore to be *R. Raphanistrum*, L.

Eighteenth Century.—In Tournefort's *Compleat Herbal* (1730, A.D.; vol. ii., p. 466), the pod of the garden Radish is well represented as slightly constricted, striated, and sharp-pointed, the flowers are purple. Tournefort describes *R. major*, *orbicularis vel volendres*, with white or purple flowers; *R. niger*, with smaller leaves and deeper jagged (serrated?). "Parkinson sowed the seed of this species, which produced plants, some of which had black roots; but the greatest part were covered with a white skin." Lastly, *R. minor*, *oblongus*, with oblong root.

In his *British Herbal* (1756, A.D.), Dr. John Hill first describes "The wild white Radish" *R. sylvestris*, *radice albente*. His figure of this is a two-seeded constricted and pointed pod; the

leaves lyrate, but the segments all connected. "It is found in some parts of Sussex, principally near the sea-coast. . . . Ray calls it *R. maritimus flore luteo, siliquis articulatis secundum longitudinem eminenter striatis*. One would think that the garden Radish was raised from this, but for the colour of the flower" (p. 243). He then describes the garden Radish, *R. vulgaris*; the round black Radish, *R. radice rotundo nigro*; and lastly, the long, jagged-leaved, black Radish, *R. foliis laciniatis radice longo nigro*. Both the last are figured, the foliage being very distinct; but the pods the same as of the first-mentioned. Hill says that the garden Radish and the last-named are natives of Spain; the round black Radish, of Italy. With regard to the colours of the flowers of the Spanish-Italian varieties, the flowers are white with a tinge of purple or red, some more, some less. The pods are jointed in all.

Taking Miller's *Dictionary* as an example, the author mentions *R. sativus* and three others as constant varieties, and *R. Raphanistrum* as distinct. It is called "the white-flowering Charlock with a jointed pod." He also observes that "the small round-rooted Radish is not very common in England, but in many parts of Italy it is the only sort cultivated."

Nineteenth Century.—In the *Prodromus Syst. Nat. of A. P. de Candolle* (1824, A.D.), we find seven species described, as well as two doubtful ones. Of *R. Raphanistrum* there are three varieties, with white, yellow, and purplish flowers; while *R. maritimus* flowers are yellow, and scarcely veined.

From the above abbreviated descriptions, it will be seen how all the characters relied upon are variable, as Bentham observes, and judging by the figures of the siliques, they certainly are constricted, but in that of Tournefort, the constrictions are much reduced under cultivation, so that it does not appear surprising that they should vanish altogether. *R. maritimus*, being a south European type, will account for the tenderness sometimes shown in the Radish; so that the general result appears to be that Radishes have been raised in many countries from the local sub-varieties of this variety of *R. Raphanistrum*, L. George Henslow.

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT CHEAM PARK.

THE beautiful garden of F. C. Jacomb, Esq., in Surrey, has been long noted for the excellence of its Orchids, especially *Odontoglossums* and showy *Cattleyas* and *Lælias*. A few years ago, Mr. Jacomb replaced the long range of old lean-to houses by new ones better adapted to plant-culture, but in which he repeated the roomy and lofty character of the old houses. About the same time Mr. James Turner, now head gardener at Cheam Park, took charge of the garden and grounds, the plant, fruit, and Orchid-houses included. Following these alterations, the Orchids made a fresh start, and now they far surpass in vigour and floriferousness anything seen in the garden previously. On Sundays the gardens and pleasure-grounds are thrown open to the public, and on the first day they were opened this season there were nearly one thousand visitors. For this occasion, and at the time of our visit, the three large plant houses were very gay, being skilfully arranged with fine examples of *Odontoglossum crispum*, *O. Pescatorei*, *Cattleya Mossiae*, *C. Mendeli*, and *Lælia purpurata*, intermixed with other stove and greenhouse flowering and foliage plants. Overhead were suspended varieties of *Cattleya Mossiae*, all of which were of a very handsome type and some of them distinct, notably one very large

flower, in which the greater part of the labellum was of a bright orange-colour, resembling that of *C. Dowiana*; and another with medium-sized flowers, of a very dark tint of crimson, the colour throughout being very fine. The dozens of fine specimens of *Cattleya Mendeli* also showed great variation, no two of them being alike, their flowers varying from blush-white, with only a little crimson colour on the lip, to rose-colour, with crimson-purple labellum. The finest of this class is *C. Mendeli* "Her Majesty," with which Mr. Jacomb secured a Silver Medal at Manchester a few years ago, and which he prizes very much. One form is very pretty and peculiar, the tube of the lip being of a glowing orange colour.

Cattleya Warscewiczii is also represented by some very fine specimens, and prominent in the charming display are *Laelia purpurata* Schrodæ, with nearly white flowers; some good specimens of *Miltonia vexillaria*; a few handsome spotted forms of *Odontoglossum crispum*; *O. luteo-purpureum*, very finely flowered; several graceful plants of *Thunia Marshalliana*, *Dendrobium Dalhousieanum*, *D. chrysotoxum*, *Cattleya labiata* Warneri; some good *Odontoglossum citrosum*; a number of finely-grown *Cattleya Harrisoniae*, producing flowers freely; two fine examples of *Cypripedium Rothschildianum*, the one of very dark colour, bearing a stout spike of three flowers, the other much lighter in colour; *C. x selligerum* majus, and other *Cypripediums*; *Oncidium concolor*, &c.

Among the flowering plants other than Orchids in these three houses were *Allamanda Hendersoni*, the pretty blue *Torenia asiatica*, various colours of *Thunbergia alata*, scarlet *Clerodendrons* and *Anthuriums*, a very fine strain of *Gloxinias*, &c.

In the *Cattleya*-house proper the plants are vigorous and some of the best varieties are not only kept healthy, but are increased in number.

The *Odontoglossum*-house is a very pleasant sight, its large number of plants being in the best possible condition, the newly-made bulbs on the *Odontoglossums* are large, plump, and of a rich green colour, their flower-spikes stout, and bearing flowers of a very thick texture; the white and rose-tinted forms of the *Pacho* strain predominated. Also in bloom are some brightly-coloured *Masdevallias*, *Oncidium concolor*, and a few other species. The house feels cool and moist, the edges of the staging bright and fresh with the long trailing stems of the British Toad-flax (*Linaria Cymbalaria*). This elegant trailer is eminently suited for trailing over the edges of the staging in the cool *Orchid*-house, for it is compact, fresh looking, and insects do not, it is said, attack it.

In this, as in all the other houses at Cheam Park, ample provision is made for catching and storing rain-water. With a view to ensure a continuous supply, a large tank out-of-doors receives the overflow.

In one of the houses is a magnificent collection of double-flowering tuberous *Begonias*, raised by Mr. Turner from seed, and bearing large and very handsome flowers. In the borders are *Roses*, *Pæonies*, *Iris*, and other showy hardy perennials, and among the finest objects in the grounds are some noble and ancient specimens of the Cedar of Lebanon, and other conifers.

ODONTOGLOSSUM TRIUMPHANS VAR.

Mr. de Barri Crawshay writes that his variety "Lionel Crawshay" is "infinitely finer" than the var. *latisepalum*, figured in Cogniaux's *Dictionnaire Iconographique*. Nevertheless, in our opinion, they belong to the same group.

ODONTOGLOSSUM CRISPUM VAR. PRINCE OF WALES.

At the last meeting of the Royal Horticultural Society at the Drill Hall, Westminster, a plant of *O. crispum* with the varietal name Prince of Wales, was shown by Messrs. Hugh Low & Co., Bush Hill Park Nursery, the flowers of which for great substance, purity of the white, size, and general fine form exceeded anything before observed in "*crispums*."

The plant was well grown, and the inflorescence was furnished with eleven flowers. Our illustration (fig. 145) shows a flower of its true size, nearly 5 inches.

LILIES IN SCOTLAND.

THERE are only a very few Oriental Lilies which, by reason of their delicacy, are not adapted for garden-cultivation, the majority of them being of Indian origin. Among these are such varieties as *Lilium Lowi* and *L. nepalense*, which, though highly distinctive in their colouring, do not grow very vigorously, and are extremely sparing of their flowers. Of similar characteristics and equal limitations are *Lilium Wallichianum* and *L. neilgherrense*. It is but seldom that these Lilies are seen, even in a conserva-

that this great Lily takes such a length of time, generally four years, to build up the greatness of its vast flowering bulb; but on the other hand, it may truly be said that the patience of the earnest cultivator is amply rewarded when its full stature has been reached, and its noble flowers appear. Though a great bulb, it becomes exhausted in the effort to bloom adequately; but it usually throws out at least two offsets to ensure its perpetuation.

One of the finest and most reliable Lilies for garden decoration is *Lilium candidum*. It received this name from Virgil, the greatest of the Roman poets, who was, as his writings sufficiently testify, a lover of flowers. Propertius called it, with even more expressiveness, *Lilium argenteum*, the silver-hued Lily. It is worthy of both names; also, let me add,

FIG. 145.—ODONTOGLOSSUM CRISPUM "PRINCE OF WALES."

(See also Report of Royal Horticultural Society, in *Gardeners' Chronicle*, June 18, 1898, p. 385.)

tory, for which, among other reasons, their absolute unsuitability for out-door cultivation is not to be regretted; for under any circumstances they are seldom very gratifying in their floral results. One might naturally expect that species like *L. Wallichianum*, which are found for the most part among the Central Himalayas, growing in that mountainous region at a considerable elevation, ought to be of a somewhat harder constitution.

A notable exception to the general rule of Indian Lilies is *Lilium giganteum*, which, in a garden in the south of Scotland, attained last year to the imposing height of 13 feet; the magnificent specimen to which I am referring producing twenty-one perfectly formed and highly fragrant flowers of normal dimensions. Another, in the gardens of Logan House in this parish, where *Lilium giganteum* always grows grandly, promises to prove, when it has reached its full development, almost equally majestic. It is a pity

of that sacred benediction generally associated with the lustrous beauty of *Lilium chalcidonicum*, in which it is affirmed that "even Solomon in all his glory was not arrayed like one of these." The Scarlet Martagon is also an admirable Lily for the garden, towering with great facility, and like many other members of the Martagon section, growing stronger every year after the first season—let us say of preparation in the form of root-production. Such are also the qualifications of *Szovitzianum*, *pardalinum* (the Californian "Panther Lily") and *Lilium Humboldtii*, which belong to the same sub-genus, and are equally vigorous, prolific, and enduring. Their colouring is also highly artistic; and when planted in situations where they can be seen to advantage, their effect is superb.

Lilium auratum, perhaps the most popular of Japanese Lilies, is of a widely different character, seldom lasting in any situation for more than three

years. After that period it generally deteriorates, and fails to produce impressive results. This is a fact which is greatly to be regretted; for though it possesses a very objectionable perfume, this imperfection is greatly modified by the action of the atmosphere, and it is unquestionably grandly ornamental. Perhaps it is in virtue of their more refined fragrance that I prefer the *L. speciosum*, especially the pure white variety called *L. s. Kraetzeri*; but they are also of somewhat stronger vitality than most of the forms of *Lilium auratum*, and much longer lived. *Lilium Krameri* is an exquisitely beautiful Lily, but difficult of culture, for which reason I trust that the new pink-coloured Lily, *Lilium rubellum*, introduced by Messrs. Wallace, of Colchester, and figured in our issue for May 28, 1898, p. 335, may prove at least, in the direction of hardiness and vigorous growth, a greater acquisition. It is not every season that suits *L. longiflorum* when cultivated in the garden; but

as in Keswick Codlin, to the penetrating spicy odour of Cloves. In some parts of Scotland "Flourish" or "Flourishing" is the pretty designation applied to Apple-blossom, words directly derived from the French, but which appear not to have extended south of the Tweed. So beautiful indeed are some of the trees with "flourishing," that one is compelled to the conclusion that it might be by no means amiss to cultivate only those Apples which, as decorative objects when in flower, are no less valuable than for the high quality of their fruits. An inspection of the more beautiful flowering varieties, show that these dual qualities are not at all rare. It is hardly necessary to give examples of popular Apples that excel also in the beauty of their flowers, but a very few of such will include Bismarck, with shoots enveloped in closely-set trusses; King of the Pippins, of great effect; Lord Suffield, a delightful variety with large pink blossoms; Manx Codlin, more profuse

and pretty features in kitchen gardens at this time of year; but one ineffective tree in a line will detract much from the general good effect. Hence, where such must be cultivated, they may be arranged in some part of the garden not greatly conspicuous.

It is, however, in the planting of espaliers that the full effect of planting injudiciously Apples for their flowering qualities is most forcibly presented. If Irish Peach, Court Pendu Plat, and Worcester Pearmain are associated, the crop may be satisfying, but the harvest of blossom will not. But by the simple method of planting one variety only on each stretch of espalier, or by associating those varieties which, while flowering at the same time, are much alike in colour and size of bloom, success in this point is assured. It is by no means a new idea, this of planting one sort only on one espalier, because exactly 180 years ago Switzer recommends Golden Pippins and Codlins to be planted in this manner. Not that he had any thought of flower-effect, but merely because these were the two Apples then in greatest repute, and he thought they were the best dessert and culinary varieties to grow by themselves.

There is here a very interesting example of the one variety arrangement. It occurs in a long covered walk (over 400 feet in length), in the way of the old French "tonnelles," and only one variety of Apple is grown on it. Though planted only six years, the effect is already very good; and, of course, there is no break in the bloom from end to end, while the green of the foliage and the tint of the blossoms is in each case unchanging. With espaliers it is perhaps unnecessary to be quite so uncompromising; Lord Suffield, New Hawthornden, and Manx Codlin, or Ribston Pippin, Tom Putt, and King of the Pippins could be associated with excellent effect.

One or two other points in connection with Apple flowers is worthy of consideration. I shall mention only two; and both involve a critical knowledge of the different varieties as flowering subjects which, as I suppose, comparatively few have. The first is the hardiness or form of the flowers as factors towards securing a crop of fruit. Court Pendu Plat has long afforded, by the lateness of its flowering, an example of an Apple that crops more or less regularly. But opposed to mere lateness of flowering as a singular means of attaining fruitfulness, it is admissible to point to Irish Peach as an instance of an early-flowering variety that is, to say the least, not less a certain cropper than the first-named. Then we have the curious fact that some varieties, which flower no less abundantly year after year than fertile varieties which never fail, are hardly ever known to bear fruit. [In Scotland?] Others again flower profusely, but very seldom indeed do they set a crop that it is necessary to thin; while yet others, even in bad seasons, continue in an unbroken course of ever-flowering fruitfulness. There is, of course, more than mere blossom to be considered, but there can be no reason for doubting its influence.

Perhaps no variety exhibits more the effects of frost and sunburn in its flowers than Early Margaret, a variety that has been cultivated uninterruptedly for three hundred years or more. But the petals of its white flowers slightly incurve, and although the effects of frost may be apparent on the petals, the stigmas appear to be protected from injury. In Worcester Pearmain we have a variety which from the narrowness of its petals, along with their wide expansion, is peculiarly susceptible to frost. Loddington and Warner's King are examples of a type that seldom or ever requires thinning, and this obviously a result of the wide expansion of the blooms which protect the fructifying organs neither from morning frosts nor midday scorching suns.

Leaving these practical matters, I shall refer very briefly to the other point, which is largely academical, though not without its value. It is the help that a critical knowledge of Apple-flowers would be in the determination of names. Some sorts are doubtless much alike, but taking the form of the pip and of the truss, the shape and tint of the petals, and, perhaps as helpful as any of these, the time of flowering, an almost certain method of determining nomenclature is ready to the hand of those who have leisure

FIG. 146.—EPI-CATTELYA RADIATO-BOWRINGIANA: ROSE-PURPLE COLOURED, WITH DARK-PURPLE MARKINGS ON THE LIP.

when atmospheric conditions are very propitious, such varieties are *L. giganteum*, *L. Harrisii*, and *L. Takesima* will grow and flower with considerable success. They are always finer, however, when grown under glass. David R. Williamson.

EPI-CATTELYA × RADIATO-BOWRINGIANA.

OUR illustration shows one of Messrs. J. Veitch & Son's hybrids, obtained from *Epidendrum radiatum* crossed with *Cattleya Bowringiana* (fig. 146). The plant has the habit of the first-named species, but the petals and sepals are of a rosy-purple tint, with a lip that is marked with purple lines of a darker tint. The pseudo-bulb is ovoid and flattish. A plant was shown at the Royal Horticultural Society's meeting on June 14.

"FLOURISHING."

A REMARKABLE year has been the present for its Apple-blossom, charming the eye with its profusion as it gratified the sense of smelling with its fragrance, even

and deeper tinted than the last-named, though the flowers are very small; Tom Putt, the lovely blush, almost white, flowers of which are arranged in large trusses.

Apple-trees with large deep-blush blossoms, are represented by many varieties, of which I name Loddington, Warner's King, Bramley Seedling, Tower of Glamis, and The Queen, Ribston Pippin, with flowers nearly white, is fine; and Early Margaret, though of less decorative value than any of the above, is also a white-flowered variety, very distinct and also pretty. Adams' Pearmain and Cox's Pomona, represent those with fawn-tinted flowers. These examples, which anyone may extend into a longer list, indicate the hopefulness of uniting in the cultivation of the Apple, beauty with utility.

If it is asked, in what manner are we to go about in order to secure this *utile dulci* in Apple culture? I think, not by interfering with orchards, nor with tall standard trees in gardens, but certainly with bush trees and pyramids, and more particularly with espalier trees. Lines of the two just named in conjunction, planted between quarters, may, by a proper selection, be made to form very interesting

and a competent knowledge of Apples to apply those marks aright. It is notorious that fruit from different localities, or off varying soils, varies very considerably. Flowers, on the other hand, are a fixed quantity, and therefore not to be ignored; and, at any rate, a knowledge of the flower that any given Apple produces would do much to clear the haziness that at present exists in the naming of the fruit.

The question of Apple-blossom in any of its aspects is full of interest, and even in the garden, as I have endeavoured to show, there is room for an improved disposal of the many truly lovely varieties of Apples which render May redolent. A step in the right direction will be the recognition of their capacity to render very many interesting gardens still more interesting. It is a step, therefore, that those who are called upon to select Apples to plant in new or improved gardens might do well to take. It entails no loss of fruit—perhaps the result will be a larger supply; and it is obvious that it would add largely to the beauty of the garden were the Apples to be arranged according to the affinity of their flowers. *R. P. Brotherstone, Tynningham, N.B.*

THE BULB GARDEN.

IRIS SIBIRICA AND ITS HYBRIDS.

THREE or four years ago I was walking with Mr. G. F. Wilson in his famous Iris meadow at Wisley, then more beautiful with flowering Irises than the Homeric meadow of Elysium, ever could have been with Asphodels.

Amongst the countless flowers were some like *Iris sibirica*, but much larger. Mr. Wilson told me they must be self-sown varieties, and a little inspection led me to conclude that they were hybrids between *I. sibirica* and *I. virginica*, as they grew where these two species predominated; and with his usual liberality, Mr. Wilson gave me some fine specimens, which I selected.

About the same time there came into flower in my garden at Edge, plants from seed sent me by Mr. Thompson of Ipswich, as *Iris koreana*, a name which is not enumerated in *Index Kewensis*. The flowers, although from both sources they vary a little, agree in size and general characters, and probably have the same history. I call attention to them, because of all the somewhat large class included under the name *I. sibirica*, they are by far the best. In this garden hundreds of seedlings have come spontaneously and flowered from *I. sibirica*, including its white variety, and though they vary a good deal, not any have come like these I mention. A well-known form *I. s. var. orientalis*, with red spathes and buds, was so sparing of its flowers in spite of varied treatment, that it has long since been all consigned to the rubbish heap, but in these supposed hybrids the flowering is abundant. The size of the flowers, when the falls are extended horizontally, is about 5½ inches, typical *sibirica* being about 3½ inches. The form, whatever it is, is well worth the attention of gardeners, to many of whom it is probably known already. *C. Wolley Dod, Edge Hall, June 16.*

TREES AND SHRUBS.

AZALEA INDICA OUT-OF-DOORS.

WHEN visiting recently, Clyne Castle Gardens, near Swansea, the residence of Graham Vivian, Esq., I was deeply interested in some fine groups of *Azalea indica*. The principal group contains thirty-five plants; one of these, *indica alba*, stands 4½ feet high, and is 12 feet through, and was one mass of blossoms. A plant of the variety *Deutsche Perle* measured 4 feet through, and a plant of *A. Borsig*, with double, pure white flowers, 5 feet through. *Duc de Nassau*, a rosy-purple-flowered variety, was 6 feet through; *Madame van Houtte* is represented by a plant 7 feet in diameter; and *A. Sigismund Rucker*, lilac-rose

flowers, 6 feet. There are some twenty distinct varieties, including several good plants of *A. amona*. The gardener, Mr. Foote, informed me that the majority of the bushes had been planted some twenty years. It would be interesting to know if there is another such collection in this country. The plants have withstood twenty winters without any artificial protection. *R. Milner, Penrice Castle Gardens.*

SCOTLAND.

MARKET-GARDENING AT LOANS, AYR-SHIRE.

SINCE the time—now about four years ago—that Mr. H. F. Bennie, of Barassie, leased a piece of ground at Loans village, about 2 miles from Troon, erected a range of greenhouses, and commenced the cultivation of Tomatoes, &c., he has had a fair measure of success. The nursery is situated at the south end of the village, and extends to 3 or 4 acres on each side of the Troon road. On the north side there were previously six forcing-houses, each 150 feet in length, but this year sufficient land has been taken in, and three others erected. These latter are massive glass frames, 102 feet long, and instead of being fixtures, they are built on wheels, and run on rails at a distance of 300 feet across, carrying a patent saddle-boiler to heat up the three houses by means of steam-pipes. They were built by the patentees, the Horticultural Travelling Structures Company, Limited, 2 and 3, White Street, London, E.C., and are the first of the kind erected in Scotland. As different crops require different soil, the expense of wheeling out and putting in fresh earth for each crop is saved, the structure being simply moved to the place where protection is required. In the south of England these travelling structures are used to force forward three crops, namely, Tomatoes, Chrysanthemums, and Strawberries. The Tomatoes grown at Loans, which are of first-class quality, are principally sent to Glasgow, the output last year being about five tons. Each year marks an advance in the quantity of Loans' Tomatoes consumed in Troon, which need not be wondered at when the quality is considered. The south part of Mr. Bennie's nursery is used for the outdoor cultivation of flowers for cuttings, &c., in which a good trade is done. In Scotland generally the chief drawback to such undertakings being successful at present is the rating of the land at feuing instead of agricultural value; but in time this may be put right, to enable growers to compete with England and foreign countries. *D. S. Millar.*

THE WEEK'S WORK.

FRUITS UNDER GLASS.

By G. NORMAN, Gardener to the Marquess of SALISBURY, Hatfield House, Herts.

Planting Vines.—Vines which have been raised from eyes this year may be planted in the place of worn-out Vines whose produce is gathered. Such Vines have still sufficient time to become established this year, and for the canes to reach the length of a rafter in an ordinary vinery, and the side shoots partly to cover the intervening spaces. If a Grape-room exists there is no need to wait till the Grapes are consumed, but they may be cut and bottled. The new work will involve a thorough cleaning of the vinery-walls, glass, woodwork, &c., digging out the worn-out soil, putting the drainage in order, and temporarily bricking-up the arches or openings in the front walls of the vinery, and wheeling in the new soil. If a new border, the entire length of a vinery, has to be made, it is a much simpler affair than mere patching; and as a border deteriorates from year to year, it is advisable to make at the start a border of 3 to 4 feet wide, and to add 1 foot or 2 feet to it annually. Having made up the border of well-chosen materials, scoop out broad shallow holes, then partially shake out the Vine-roots, spreading them around in the hole, and cover with a couple of spadefuls of nice light soil, fill in a little, afford a gentle but copious application of water, and fill in finally. Now proceed to fasten the young Vine to a stick; then having planted and tied up every Vine,

damp down, and close the house, and maintain it in a close, warm condition, shading the Vines for ten days only, i.e., till they push forth their roots into the new soil, when more air may be admitted, and the Vines treated in a manner corresponding to that advised for early ones. As regards future additions of soil to the border, the various points insisted upon in regard to drainage, flooring of concrete, &c., should be strictly adhered to. Vines this year struck from eyes intended for fruiting in pots, if they are well furnished with roots, and are growing in 8-inch pots, may be shifted into 11-inch ones. Let the potting be firmly performed, and on no account let them lack water at the root; on the other hand do not sour the soil by unnecessary applications of water. The sound given forth by a pot when rapped will show if water be wanted or not. Cut-back Vines are best for the earliest crops in pots, and one-year-old Vines to follow them. When the pot-Vines are 7 feet long, nip out the point of the stem, and compel the dormant bud at that point to break; and pinch the side shoots back to one leaf each, this holding good of Vines from eyes this year and cut-backs. Cut-back Vines should by this time have made progress in the pots they are intended to fruit in, and will stand in need of very careful attention in the matter of root-watering. Maintain the house in which they are growing in a moderately moist condition, syringing the Vines twice a day, and affording free ventilation. The inarching of Vines should be carried out at this date, but there must be no delay in getting the operation done. The united Vine will, under favouring conditions, still have time to grow to the top of the vinery. At a suitable point select a young shoot low down on the rod, and place a potted Vine of this year's striking in a position convenient for being inarched to it. The union must be made where the wood is firm. Take off a slice about 2 inches long, and half-way through the stem and the shoot place the two surfaces together, and secure them with broad strips of bast. A short time suffices to make an union. Soon after the scion has taken, the ties must be replaced with looser ones, and this operation may have to be repeated. The root and part of the plant below the splice must not be removed till it is seen that a complete union is effected.

The Strawberry.—The runners for next season's forcing will shortly be in excellent condition, the recent rains having benefited them greatly, and to avoid any drawback from dry weather, applications of water will be required. It is a good rule to begin layering before the first runner has had time to put forth roots, and to pinch off all runners beyond the first. If pots be used, large 60's are a very suitable size, and these should be filled with fine loam to within half-an-inch of the top, and made somewhat firm by hand pressure. Having placed the pots, secure the runners on the soil with hooks, &c., and afford water every afternoon when there has been no rain to moisten the soil. If sufficient runners are not found when looking over them the first time, another examination should be made about ten days later. In order to avoid treading on the runners and bruising them, turn the runners from two rows of plants on to the space between the same two rows, and use the alleys on either side as paths.

THE ORCHID HOUSES.

By W. H. WHITE, Orchid Grower to Sir TREVOR LAWRENCE, Bart., Burford, Dorking.

Cattleya or Intermediate-house.—*Aganisia cœrulea*, whose flowers are almost identical in colour with those of *Vanda cœrulea*, is also like the same species, difficult to cultivate successfully for a long period. It thrives best when fastened to a piece of Teak board, with a little sphagnum-moss attached, to keep the roots moist. Place it with such plants as *Bolleas*, *Pescatoreas*, &c. *Vanda Kimballiana* and *V. Amesiana* should now be placed in a light and well-ventilated position. Do not keep the rooting material in a saturated condition, or the terete leaves will become spotted and fall away; but afford just sufficient water to keep the moss fresh and green. Their immediate surroundings, however, must be made constantly moist until the flower-spikes appear. Old plants of *V. cœrulea* that are not thriving satisfactorily, now that root-action has commenced, should be taken out of their pots or baskets, and fastened to bare Teak rafts. Suspend them in a light airy position, and syringe the stems and roots several times a day until growth is completed. Plants that are growing well and are healthy will only need re-surfacing with fresh sphagnum. *V. teres* and *V. × Miss Joaquim*, now in bloom, grow and bloom profusely in a moist sunny position in the

ordinary plant-stove; they require to be syringed overhead several times a day during active growth, for if allowed to become too dry the lower leaves will shrivel and fall. *Cattleya Schilleriana* having bloomed, should be suspended in a cool position in this house, very little water being needed to keep the growths plump. *Brassavola Digbyana*, if strong, will be pushing up its flower-spikes; the plant at this time should be placed in the warmest and lightest corner of the house, and be afforded generous treatment until the flowers open. The curious *Dendrobium Brymerianum* makes stronger bulbs and blooms more profusely in this division than in the East Indian-house. Plants now starting to grow may be repotted if necessary. Those who possess several plants would do well to suspend one near to the roof-glass, and place the others upon the stage with the *Cattleyas*, &c. When the plants have become well rooted they will need copious waterings, and syringe well up under the leaves to prevent red-spider obtaining a footing. *D. x Victoria Regina* grows well in an intermediate temperature. Secure the plant to a Teak raft, and lightly cover the roots with sphagnum-moss. Sprinkle the moss occasionally, and the plant will grow luxuriantly. *D. Coelogyne* and *D. cymbidioides* also grow well if suspended close to the roof-glass in this house. Plants of *Odontoglossum Londesboroughianum* now making their growths, should be carefully watered, and none must be permitted to enter the young breaks. This lovely species deserves every attention, and it should be placed in the lightest position in the house. *Lælia majalis* now growing and rooting freely, requires plenty of root moisture until growth is finished, and a cool light position at all times. The rare *Coelogyne Sanderiana* has now passed its resting season, and no amount of dryness will cause the plant to flower if it has not been properly rested. As the new breaks appear place the plant where it will obtain plenty of light without direct sunshine, and water the plants copiously. Repotting may be done when the flowers have faded, or in the absence of flowers, as soon as the young roots appear. *Maxillaria Turneri* is now in bloom, and the scent of its flowers pervades the whole house. It grows freely when potted in ordinary Orchid compost, and requires a rather shady position in the intermediate-house. In the cool-house here the tips of the leaves become black and decay. Immediately the plants of *Coelogyne Dayana* have passed out of bloom they may be afforded fresh rooting material, and the usual care afterwards practised in watering them. This *Coelogyne* may be grown in pans or baskets, and if suspended to the roof of the house the long pendulous flower-spikes will display themselves perfectly. *Odontoglossum pulchellum* is commencing to grow afresh, and may be repotted. Afford plenty of drainage-material, and use a compost of three-parts sphagnum-moss to one of peat, and a few pieces of broken crocks. Fix the plant well above the rim of the pot, and press the soil rather firmly around its base, and place it at the warmer end of the house.

THE KITCHEN GARDEN.

By J. W. McHATTIE, Gardener to the Duke of WELLINGTON, Strathfieldsaye, Hants.

Globe Artichoke.—This valuable vegetable, during its growing season should be afforded copious root-waterings, alternated occasionally with liquid-manure. Some of the heads are now ready for the kitchen, and in cutting them off remove the stalks also to within a few inches of the ground-level, that they may cease to draw further nourishment from the roots of the plant. New plantations, whether made with seedlings or suckers, should be given every attention that will encourage the plants to make free and rapid growth. The surface of the soil may be frequently disturbed by hoeing, and during dry weather root-waterings will be needed.

Leek.—To obtain very large fleshy Leeks it will be necessary to afford the plants frequent supplies of weak liquid-manure during the remaining part of their growth. The ground may be kept in a sweet state by frequently stirring the surface with a hand-fork or hoe. The leaves being sometimes damaged by wind, it is a good practice to afford exhibition plants support by placing sticks to them.

Herbs.—When Mint, Thyme, Sage, Balm, and other herbs show for bloom, a quantity of each should be cut during fine weather, and be afterwards tied up in small bunches and suspended in a dry airy shed, free from strong sunshine. They will thus dry slowly, and be valuable for winter use.

Salsify and Scorzoneria from seed sown as directed should now be thinned, and the ground ridded of

weeds. For either purpose it is better to use the hoe than effect the operation by hand.

Affording Water to Vegetables.—During a hot summer liberal supplies of water are doubtless of exceeding benefit to most garden crops, and should there be a good and convenient supply of water all over the gardens, the trouble and cost of applying water will be very trifling compared with the advantages that will follow. When water is necessary, let it be afforded in the evening, or, failing this, in the early morning; the same amount of water applied at night will have greater effect than at any other time, owing to the atmosphere being less conducive to evaporation, the water will the better sink into the soil. But if water cannot be thoroughly applied, and followed up, then the better plan will be not to afford any. Other means may be taken to prevent evaporation from the soil, and thus preserve what moisture it still possesses. It is not sufficiently recognised how much may be done by mulching with manure, short grass from the lawn, stable-litter, or rotten tan between the rows of vegetables. Some crops, as for example, salads may be shaded with mats during the heat of the day. Bent stakes placed in the same manner as for protecting early Potatoes will afford the necessary supports. Frequent and fairly deep hoeings are of the utmost value in helping the crops to withstand drought, and many large and successful fruit growers rely upon this means alone—watering in such cases being impracticable. Lettuce or other plants that have been transplanted must, of course, be afforded water at the roots as they require it.

HARDY FRUIT GARDEN.

By W. H. DIVERS, Gardener to the Duke of Rutland, Belvoir Castle, Grantham.

Pears.—If early varieties of the Pear have set their fruits thickly, they will now be, in most parts of the country, large enough for being thinned, and the best instrument to perform the job is a pair of ordinary Grape-scissors. First remove the undersized and deformed ones, and thin the remainder, so as to leave the crop as evenly distributed over the tree as possible. Some kinds, as *Fondante d'Automne*, *Summer-Franc Real*, fruit in clusters, and come to a fair size if five or six be left in a cluster; and *Doyenné d'Été* and *Citron des Carmes* are chiefly valuable for their earliness, and these should be thinned somewhat, besides the trees being afforded manure-water. In point of earliness, *White Doyenné*, *Jargonelle*, *Beurré Giffard*, and *Williams' Bon Chrétien* follow close on the last two, and they occasionally set heavy crops of fruit; the three last grow to a large size under good cultivation, and require severe thinning to obtain fine specimens, not more than two fruits being left in a cluster. A mulching of farmyard manure, and an occasional application of weak manure-water will now be of great assistance to the trees. Late varieties may be left a fortnight later before thinning the fruits.

Training.—All young fruit-trees should now have the leading growths, whilst still pliable, secured by shreds or ties; but the summer pruning should be delayed till the new shoots get firmer, when there is less danger of the dormant buds pushing into growth. Shoots which grow too freely had better be stopped if they seem likely to disturb the balance of growth or render weak shoots still weaker. Weakly trees with unhealthy-looking foliage should be stimulated by manure-water at the root, and a part of their crop of fruit removed.

Morello Cherries.—See that the trees are thoroughly free from aphids before the fruit commences to colour, as it is inadvisable to apply insecticides afterwards. The safest remedy for the black aphid that affects Cherry-trees is suds made with soft-soap 4 oz. to a gal. of rain-water, to every 3 gal. of which a quarter pint of tobacco-juice is added. This should be applied with a wall-tree engine or powerful syringe, and after the lapse of a few hours the trees should be syringed copiously with clean water.

PLANTS UNDER GLASS.

By W. MESSENGER, Gardener to C. H. BERNERS, Esq., Woolverstone Park, Ipswich.

Richardias.—Where some or all of the stock of this plant are grown, turned out of their pots in the open ground, a piece of land somewhat shaded from the midday sun and of good depth, should be heavily dunged, and deeply dug in readiness for planting within a week or two. Let the plants be shaken out of the old soil, and the decayed leaves

&c. removed, the masses reduced in size, and broken roots cut off, then proceed to plant at a distance of 2 feet apart in lines, making a shallow basin round each for the better affording of water. The object of planting out is to the production of vigorous plants for lifting in September or October.

Cinerarias.—Plants from the earliest sowing being now large enough may be shifted into large or small 48's, and the smallest into 60's. Plants from later sowings will be in need of pricking-out into pans or boxes. A cold frame behind a hedge or wall, and facing north, is a suitable place for *Cinerarias* at this season, the pots and pans being stood on a coal-ash bottom, with a sprinkling of soot over it. Here the conditions will be such that no shade is required to break the force of the sun with the result of weakening growth, and thrips and red-spider are easily kept in check. A close watch must be kept for slugs. Seeds may still be sown.

Begonias.—The autumn and winter-flowering varieties that are in need of repotting may at this shift go into the flowering-pots, but only those which have made plenty of roots should be afforded so large a shift, the remainder waiting till they have made more roots. Stand them all together in an unheated pit or garden-frame, affording air freely by day, and a slight shade when the sun is bright, and syringing among the pots freely once or twice a day, not wetting the leaves in bright weather, or they will be scorched and discoloured.

Cyclamens.—Those plants that have been raised from sowings made in August and September last, and potted, may, if they are well established in small 60's, be shifted into 48's. A pit or frame facing north should be allotted to the plants, and then little or no shading will be needed; and should the plants flag, syringe them frequently in preference to using shading. Take great care that the plants do not become dry at the root, and syringe them two or three times daily. *Cyclamens* raised from sowings made early in the present year will be ready for shifting from the pans and boxes on which they were pricked-off, into 2½-inch pots. The soil I find best for the plants consists of good fibrous loam three-quarters, rotten-manure and leaf-mould one-quarter, mixing enough silver-sand with it to secure porosity; and clean pots and good drainage are very essential.

THE FLOWER GARDEN.

By H. WALTERS, Gardener to Lord GERRARD, Eastwell Park, Ashford.

Bedded-out Plants.—In the event of a spell of hot dry weather occurring, the plants recently bedded-out will need water to enable them to obtain a good root-hold of the ground, that they may soon fill up the spaces intervening between each plant. The best time to afford water is the evenings. If the work be done in the early morning, and this is immediately followed by hot sunshine, some of the foliage may be scalded. A fine rose should be used upon the water-can, as the water will the better be enabled to penetrate the soil. Edging plants such as *Lobelias*, *Pyrethrums*, *Lysimachias*, *Antennarias*, and *Violas*, should be given liberal quantities of water frequently, to encourage growth. Remove weeds from among the plants as fast as they appear, and keep the edges of the beds neatly trimmed. *Verbenas* and *Phlox Drummondii* will require to be pegged evenly over the ground as growth proceeds. Annuals should be thinned out as each case requires, so that the plants may have room for individual development.

The Rose Garden.—Green-fly this season is so abundant that frequent washings will be necessary as advised in a previous calendar. Keep the ground frequently hoed between the plants for the three-fold purpose of destroying weeds, of maintaining a neat appearance, and of preventing excessive evaporation from the soil. Occasional waterings with liquid-manure from the farmyard should be afforded the plants; they will greatly benefit from them, and the blooms will be finer. Remove dead blooms from the plants, and keep the shoots on climbing, and pillar Roses tied or nailed as required.

General Work.—Use the hoe among recently planted shrubs for the destruction of weeds. Mow the lawns frequently, and keep the edges and verges trimmed. The gravel-walks should be rolled, and Box and other edgings cut. *Dahlias* and *Gladioli* may be mulched with half-rotten manure. The later batches of Sweet Peas should be staked; and if a mulching of manure be afforded the plants, they will greatly benefit therefrom. Endeavour to maintain as neat an appearance everywhere as possible.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith. The Editor does not undertake to pay for any contributions, or to return unused communications or illustrations, unless by special arrangement.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, JUNE 25	Windsor and Eton Rose and Horticultural Show. Royal Botanic Society, General Meeting.
TUESDAY, JUNE 28	Royal Horticultural Society's Committee. Royal Horticultural of Southampton Exhibition (2 days). Rose Shows at Leeds and Sutton.
WEDNESDAY, JUNE 29	Horticultural and Rose Shows at Richmond, Croydon, Canterbury and Brockham.
THURSDAY, JUNE 30	Royal Horticultural Society of Ireland, Exhibition. Rose Shows at Eltham, Gloucester, and Norwich.
SALE.	
FRIDAY, JULY 1	Imported and Established Orchids, at Protheroe & Morris' Rooms.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years, at Chiswick.—62° 5'.

ACTUAL TEMPERATURES:—

LONDON.—June 22 (6 P.M.): Max., 71°; Min., 55°.
PROVINCES.—June 22 (6 P.M.): Max., 65°, S. Coast;
Min., 51°, Sumburgh Head.
Fine, warm, windy.

Paris Exhibition, 1900. In the year 1900 the Parisians propose to inaugurate an exhibition on a larger and more magnificent scale than ever. The proposed subjects for exhibition will be grouped in eighteen groups, comprising 120 classes. "The guiding principle is," says the Prince of WALES in his inaugural address to the Commissioners, "that similar products from whatever part of the world they may come, should be shown side by side." The interests of British Horticulture and Arboriculture with which our readers are mainly concerned are to be cared for by Committee V., as follows:—

"COMMITTEE V. (Groups VII., VIII., IX., AND X. CLASSES 35-62.)

Agriculture. Horticulture and Arboriculture. Forests, Sport, Fishing, Gathering Wild Crops. Food Products.

Earl Spencer, K.G. Chairman.

Earl of Crewe.

Duke of Fife, K.T.

Earl of Dudley.

Earl of Jersey, G.C.M.G.

General the Right Hon. Sir Redvers H. Buller, G.C.B., V.C.

Right Hon. Horace C. Plunkett, M.P.

Sir Edward Grey, Bart., M.P.

Sir J. J. Trevor Lawrence, Bart.

Sir Jacob Wilson.

W. T. Thiselton-Dyer, Esq., C.M.G.

Lawrence Grattan Esmonde, Esq.

Paul J. Madden, Esq."

Dr. MAXWELL MASTERS, F.R.S., is also attached to this committee.

The horticultural division is comprised in Group VIII. :—

"GROUP VIII.—HORTICULTURE AND ARBORICULTURE.

CLASS 43.—APPLIANCES AND PROCESSES USED IN HORTICULTURE AND ARBORICULTURE.

Implements for gardeners and nurserymen: spades, pickaxes, hoes, lawn-mowers, garden-rollers. Tools for pruning, grafting, gathering, packing, and transporting produce: pruning and grafting knives, ladders, &c. Props. Watering apparatus.

Apparatus and objects used for ornamenting gardens: vases, pots, chairs, garden-seats, fountains, labels, &c.

Glass-houses and their accessories; heating apparatus; mats, &c.

Window and room conservatories.

Aquariums for aquatic plants.

Garden architecture: plans, drawings, models, books, pictures, &c.

CLASS 44.—KITCHEN GARDEN PLANTS.

Kitchen garden plants cultivated on a large scale, vegetables from market gardens: Potatoes, Cabbages, Carrots, long Radishes, Radishes, Capsicums, Artichokes, cultivated Mushrooms, Cress, &c. Fresh specimens.

CLASS 45.—FRUIT AND FRUIT TREES.

Species and varieties. Trees grown in the open; trees trained against walls.

Specimens of the products of cultivation on a large scale (orchards, orangeries): cider Apples and Pears, Cherries, Plums, Oranges, Lemons, Almonds, Nuts, &c.

Specimens of the products of garden cultivation: fruit grown in the open; wall fruit. New species and varieties.

CLASS 46.—TREES, SHRUBS, ORNAMENTAL PLANTS AND FLOWERS.

Ornamental standard trees, grafted or not.

Evergreen or deciduous shrub, and ornamental trees.

Park plants, garden plants.

Herbaceous plants in open ground.

Beds and baskets of flowers. Nougays of natural flowers.

CLASS 47.—GREENHOUSE AND HOTHOUSE PLANTS.

Specimens of cultivation in use in different countries for utility or for ornamental purposes.

Forcing vegetables and fruits: specimens of products obtained.

Species and varieties cultivated for ornament: greenhouse plants, hothouse plants.

CLASS 48.—HORTICULTURAL AND NURSERY SEEDS AND STOCK.

Collections of vegetable seeds.

Nursery stock of trees, grafted or not."

Horticultural products are, so far as is made clear by the map, to be exhibited on the north side of the Seine, near the Place de l'Alma, parallel with the Cours la Reine.

We shall keep our readers informed upon the progress of this great exhibition. Nothing definite, we believe, has yet been decided as to the methods in which horticulture is to be represented. Application for space is, however, to be made to the Secretary of the Royal Commission, not later than August 20, 1898. No charge will be made for space. Goods for exhibition only will pay no customs duty. Much further general information is to be obtained from a government document published for the Royal Commission, and to be had from the Secretary, Royal Commission, Paris Exhibition, 1900, St. Stephen's House, Westminster, London, S.W.

CALOCHORTUS PURDEYI.—Among the beautiful exhibits of hardy and half-hardy plants of Messrs. WALLACE & Co., of Colchester, at the meeting of

the Royal Horticultural Society held at the Royal Westminister, on June 14, were several of the earlier Calochorti, all of them very pretty and interesting when in flower. The flowers of *C. Purdeyi* are raised on 9-inch pedicels, and are silvery-white, and they are filled with what appears as a purplish haze, as seen through the numerous white hairs that line the perianth, and cover the petals (fig. 147, p. 395).

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral Meeting of the Royal Horticultural Society will be held on Tuesday, June 28, in the Drill Hall, James Street, Westminster, 1 to 5 P.M. The Rose Show, which was to have been held on this date, is now postponed until July 12. Will all intending exhibitors please note this? At 3 o'clock a lecture on "Some of the Plants Exhibited" will be given by the Rev. Prof. GEO. HENSLOW, M.A., V.M.H.

HORTICULTURAL CLUB.—The last monthly dinner and *conversazione* for the season took place on Tuesday, June 14. As usual at this time, the attendance was not so numerous as it generally is. The chairman of the Club, Sir J. D. T. LLEWELYN, Bt., M.P., occupied the chair, and a very interesting lecture was given by Mr. C. T. DRURY, V.M.H., on "Fern Variation in Nature and Culture." The lecture was illustrated by some remarkably beautiful illustrations of Nature-printed Ferns by the late Col. JONES, and gave rise to an animated discussion; a cordial vote of thanks was accorded to the lecturer. The Annual Excursion of the Club was fixed for July 19, of which members will receive full particulars in due course.

ROYAL SCOTTISH ARBORICULTURAL SOCIETY.

—The Council of the Royal Scottish Arboricultural Society have appointed that a general meeting of the society shall be held in Edinburgh in Tuesday, August 2, 1898, at 10 o'clock forenoon. By special permission the meeting will be held in the Lecture Hall of the National Portrait Gallery, No. 1, Queen Street, Colonel BAILEY, President, in the chair. Members are invited to introduce ladies and other friends to the meeting.

—The Council have pleasure in intimating that, by the kind permission of Her Majesty's Commissioners of Woods and Forests, the twenty-first annual excursion of the society will be held on August 3, 4, and 5, 1898, in the Forest of Dean and High Meadow Woods, Gloucestershire, England.

CHISWICK.—We are glad to see that the Council has again invited the members of the council to inspect the gardens on July 5, and to lunch with them on the occasion. Progress in the right direction is also shown by the lectures to students which are in course of delivery by the Rev. Professor HENSLOW.

LINNEAN.—A special general meeting of the Society will be held on Thursday, June 30, at 8 P.M. precisely, when the following papers will be read:—Sir D. BRANDIS, K.C.I.E., F.R.S., F.L.S., "A Revision of the Genus *Elæocarpus*, Linn.; Mr. A. W. WATERS, F.L.S., "Observations on the Membraniporidae, a family of Marine Bryozoa;" Miss ETHEL S. BARTON, "On the Fruit of *Chnoospora fastigiata*, J. Agardh." At this meeting a ballot will be taken for the election of a Councillor, in the place of the late Mr. OSBERT SALVIN, deceased.

SCHUBERTIA GRANDIFLORA.—A correspondent points out the value of this plant for furnishing button-hole bouquets. It is more easily handled than the *Stephanotis*, and is more durable even in the city. The perfume is also very agreeable.

PITCHER ON LEAF OF CABBAGE.—Prof. WEISS, of Manchester, obligingly sends us specimens of this common malformation, in which the vascular bundles are arranged in a circle, and the intervening tissue forms a funnel-shaped cup. From the outer surface of this cup spring by enation numerous outgrowths, forming little frills.

REPORT OF THE MICHIGAN BOARD OF AGRICULTURE.—This is the thirty-fifth report of the

Secretary of the above Board, and with it is issued the ninth annual report of the Agricultural College Experiment Station from July 1, 1895, to June 30, 1896. The volume begins with a portrait and memoir of Mr. ENOS GOODRICH, an important man in Michigan, who died last October, just before the publication of this notice. The report of work done in the different branches or departments is lengthy and on the whole favourable; agriculture, forestry, engineering,

taught "the chemistry of the kitchen, floriculture, poultry raising, the care of bees, and the cultivation of small fruits." Also dairy-farming may be studied. Reports of the Experiment Station are those on field experiments; of the horticulturist on gardens and orchards, of the chemist, of the veterinarian, and of the botanist. The latter deals with seed investigation, plant diseases, work in the herbarium, and troublesome weeds. The entomologist and apiarist also publish

book:—"Taken altogether, the session's work (1895-96) was very satisfactory." Several "miscellaneous reports" complete the volume before us, from which we have no space to make further extract.

GRAFT HYBRIDISATION.—Every year we receive specimens of *Cytisus Adami* and its variations, and no wonder, for the occurrence is very extraordinary. Mr. DIVERS sends us from Belvoir shoots bearing white flowers intermingled with red flowers on a Thorn. The tree has been grafted about 6 feet from where the white truss was produced. The same tree has also a pink truss. The facts here, though not so remarkable as in the Adam's Laburnum, are of the same character.

BORON FOOD-PRESERVATIVES.—In their zeal against adulteration the use of boron or boric acid (used from time immemorial with honey as an application to the throats of babies), has been condemned by certain persons. In fact, borax in the quantities usually employed is not only quite harmless, but useful as an antiseptic application. What would be the effect of a colossal dose we do not know, but we expect it would be considerably less than that of an equal quantity of nitre or of table-salt. A pamphlet on the subject, published by PERKINS, BACON & Co., 69, Fleet Street, may be read with advantage.

NINTH ANNUAL REPORT OF THE MISSOURI BOTANICAL GARDEN.—This volume, brought up to March 9 of the present year, contains the Director's Report on the Botanical Garden and Herbarium, the latter institution having, we learn, received some valuable additions lately. The garden also has increased, and is flourishing; and instruction to horticultural students, and in the school of botany, bore good results. Following Dr. Trelease's report are a paper by Mr. C. H. Thompson on "A Revision of the American Lemnaceæ occurring North of Mexico;" "Notes on *Salix longipes*, Shuttlw.," by N. M. Hatfield; an elaborate "Revision of the Genus *Capsicum*," by H. C. Irish; "A List of Cryptogams collected in the Bahamas, Jamaica, and Grand Cayman," by A. S. Hitchcock; "Agave Washintonensis, and other Agaves, flowering in the Washington Botanic Garden in 1897," by J. N. Rose. There are also articles on "Cacti commonly cultivated under the generic name *Anholonium*," by C. H. Thompson; "Epidendrum venosum of Florida," by W. Trelease; "Miscellaneous observations on *Yucca* and the Missouri Dogbanes," also by Mr. Trelease; "Colouring-matter found in some *Borraginaceæ*," by J. B. Norton; "Notes on Plants chiefly from the Southern United States," by J. B. Norton; "New Disease of Cultivated Palms (*Gloeosporium Allescheri*, a palm-colour form of *G. sphaerelloides*)," by W. Trelease; and "Parnelia molliscula," by Henry Willey. The beautiful plates add much to the value of the book. Some are from most careful drawings, others from photographs.

PUBLICATIONS RECEIVED.—*Destruction of Charlock in Field Crops by spraying with Solution of Sulphate of Copper*, Reginald W. Christy and Thos. S. Dymond (Essex Technical Instruction Committee).—*Weather Influences on Farm and Garden Crops, and Report on the Phenological Observations for 1897*, by Edward Mawley—reprinted from the *Quarterly Journal of the Royal Meteorological Society*, April, 1898.—*The San José Scale, and its probable introduction into England*, by F. V. Theobald. Issued on the principle that "forewarned is forearmed," with electros supplied by the U.S. Department of Agriculture.—*Agricultural Gazette of New South Wales*, April, 1898. Includes articles on some Food Plants of the Aborigines, by J. H. Maiden; New Indigenous Food-plant, spotted Mellick; Weeds of N. S. Wales, Sheep's Burnet, Constitution of Wheat Gluten, Potato Culture, Propagation of Plants, &c.—*Contributions to the Flora of Queensland*, by F. Manson Bailey (extracted from the *Queensland Agricultural Journal*), vol. ii., part. 1. Fungi: *Uromyces*, *Phyllosticta*; Part 2, Palmæ: *Hydriastele*, *Archontophoenix*, and *Livistona*; Plants reputed poisonous to Stock (*Cycadaceæ*). Part 3, *Orchidæ*; *Liparis*, *Amary-*

FIG. 147.—*CALOCHORTUS PURDEYI*. (SEE P. 394.)

veterinary science, history, and political economy, being among the subjects studied. It is proposed by the Agricultural College to organise a ladies' course of instruction, students of both sexes to be instructed in "domestic economy. . . . Our experience in the management of students leads us to believe that the presence of ladies on the campus will be extremely helpful in elevating the moral tone of the students, and increasing their regard for the amenities of polite society." Further we read that ladies are to be

their reports here. The Bulletins include those dealing with Crimson Clover, &c., by A. A. CROZIER; Inspection of Commercial Fertilisers, by R. C. KEDZIE; Dairy Records, by C. D. SMITH; Fattening Lambs, by F. B. MUMFORD; Fruits at South Haven, by T. T. LYON; Potatos, by L. R. TAFT; Injurious Insects, by G. C. DAVIS; Tuberculosis in Cattle, by E. A. GRANGE; Pasteurisation of Milk, by C. D. SMITH; and summary of Meteorological Observations for 1895. To quote some of the final words of the

Misere, Cinum; Fungi: Phyllosticta. Part 4, Myrtaceæ: Eugenia; Orchidæ: Dendrobium. Part 5, Pittosporæ, Pittosporum, Leguminosæ, Castanosperrum, Urticacæ, Ficus, Aroideæ, Rhabdophora—*Twenty-first Annual Report of the Connecticut Agricultural Experiment Station for 1897.*—*Proceedings and Journal of the Agricultural and Horticultural Society of India for January to March, 1898.* Containing a report on a large and successful flower-show held in Calcutta in February.—*Journal of the Scottish Meteorological Society (Annual)* for 1895-6.—*Bullettino della R. Società Toscana di Orticultura*, Maggio, 1898.—*Le Moniteur d'Horticulture*, Juin 10.—*Journal de la Société Nationale d'Horticulture de France*, Mai.

ALBUCA PROLIFERA.*

I AM indebted to Mr. W. L. Turpie of Port Elizabeth, for this interesting Cape bulb. When on a visit to his native city, St. Andrews, Mr. Turpie took note of my collection of Albuca, which included *A. corymbosa*, Baker (*Gardeners' Chronicle*, 1886, vol. xxvi., p. 38; *Flora Capensis*, vi., 457), a new species sent to me by Mr. Alexander Wilson from the same district. On his return, he found and forwarded to me the species now described. His notes regarding the habitat are as follows:—"Near Port Elizabeth, in the Baakens River Valley, about 1½ miles up. The river flows into Algoa Bay. The plant (the only one I had come across) was in flower, the stem and flower being 6 or 7 inches in height. The situation was on the slope of the sunny side of the valley; the soil was clay with slight indication of saltpetre. There is little rain, but plenty of dew in the mornings. This part is always exposed to the winds and heat. The cool stream is about 100 yards off."

Under cultivation, Mr. Turpie's bulb soon produced offsets, and a great number of bulbils as in fig. 148. I cannot be sure that in nature the plants will produce quite as many bulbils, but no doubt they will propagate themselves freely by this method as well as by seed.

The shoulder bearing the offset is an extension of the outer tunic, and vascular tissue forming a ridge runs up to its apex from the base of the bulb. Before long the offset puts forth roots of its own (fig. 149), and becomes separated from the parent by the decay of the outer tunic and shoulder. A new shoulder may be formed at another point by the younger tunic, and the process be repeated. In this way a single bulb, in course of time, produces offsets and bulbils in such numbers as to cover the surface of the pot. The bulbils usually break off at an early age.

The flowers (fig. 150) are not sufficiently numerous or striking enough to render this species a valuable garden plant; indeed, very few of the Albuca are of much use as decorative plants. Even *A. Nelsoni*, the finest of them, exhibits the undesirable feature, common to all, of remaining closed like a bud in dull weather. I may mention, however, that a ternary hybrid of my own, having *A. Nelsoni* in its parentage, shows a disposition to overcome this peculiarity.

The present species is one of the most diminutive of the genus. The flowers are commonly only three in number; they are, however, extremely fragrant. The fragrance is not perceptible when the flower is closed. I know of no species which exhibits in so marked a degree the separation of the inner segments

in strong sunshine. In many species separation does not take place at all, unless when an insect pushes a segment back for a few seconds to reach the honey at the base of the ovary. *John H. Wilson, D.Sc., St. Andrews.*

HOME CORRESPONDENCE.

OAK-CATERPILLARS, ETC.—It is well known that this and every other insect-pest varies in abundance, according to the year, and according to the locality. My experience this year, confined to two of the home counties south of the Thames, is that for many years past I have never seen the Oaks more free from insect attacks, or more healthy-looking in every respect. But unfortunately my experience does not appear to be generally shared. Having regard to the general devastation noticed for several years past, one cannot help marvelling at the vigour of the trees after so many repeated attacks on what should be almost a vital part of their economy. The season is backward, and it may be that the worst has not yet arrived; but I think there are sufficient indications that in some districts, at any rate, the energies of the trees in putting forth fresh leaves will not be called upon. The past winter should have been one of the most fatal on record for insects whose larvæ or pupæ hibernate (this scarcely affects the Oak-caterpillar). With regard to white butterflies, I may say that there is a strong suspicion that the swarms now seen in many places do not all consist of British-bred individuals. *R. McLachlan.*

CATERPILLAR AND THE BIRDS.—Your correspondent, "T. J. Levett," p. 384, sends a very interesting letter on the above subject. This district is famous for its Oak trees, and an old timber merchant assures me that, when Oak was largely used in the Royal dockyards, the timber grown upon the heavy land of this district was of the best quality, being easily worked and extremely durable. I do not share your correspondent's fears for the destruction of our Oak woods, as the British Oak, like the British man, is a very tough subject; and I notice that the midsummer shoots always seem to clothe the trees in spite of the ravages of the caterpillar, and even after the severe attacks of the past three or four years our trees show no lack of vigour. I fancy there has been a disturbance in the balance of Nature, caused by the severe winter of 1895, which from January until March kept the surface of the earth hard and bare, and thousands of insect-eating birds perished by cold in consequence. The caterpillar plague is not nearly so destructive on the Oak trees this year as in 1896 and 1897; and although we have several hundred Gooseberry-trees, I have seen no trace of the Gooseberry-caterpillar, thanks, I think, to an abundance of cuckoos. Our best practice is to protect and encourage the birds, and all of the varieties named by the Editor on p. 384 are our friends. I would also add chaffinches; but from a gardener's point of view, the only bird that I think necessary to destroy is the bullfinch. Provide plenty of netting, and protect your Strawberries, Raspberries, and bush fruit, as it is only during the ripe-fruit season that birds do damage to garden crops. Sparrows may require to be kept within bounds in some localities; but in truly rural districts, although they abound, they do us very little damage. I should advise your correspondent to join the Society for the Protection of Birds, and to instruct the children of the district in the habits and uses of birds in Nature. Mrs. F. E. Lemon, Hillcrest, Redhill, Surrey, is the Secretary to the above society, and will give every necessary information by circular and otherwise. *R. M., Newbury.*

INSECT PESTS ON FOREST-TREES.—With reference to Mr. T. J. Levett's remarks on the "Oak-leaf Roller Moth," in last week's *Gardeners' Chronicle*, it may interest him and relieve his anxiety to know that no permanent injury to the Oaks need be feared from these caterpillars. In this district (North Wilts) the Oaks in 1893 and 1894 were entirely stripped of their foliage by this pest, but during the last two or three years their number has been so small as to render their ravage imperceptible. In both of those seasons, however, the end of July again saw the trees covered by healthy foliage, the only ultimate result of the attack being a probable loss of growth in the wood-ring, the destruction of the acorn crop, and a late colouring of the leaves in autumn. The temporary nature of the injury is

owing to the fact that the leaves only and not the shoots or buds are eaten by the caterpillars, and therefore the normal development of the midsummer shoots after the larvæ have changed into the pupal state is not interfered with. This season our Oak foliage is particularly healthy, although occasional caterpillars may be found, but nothing approaching the numbers found in past seasons or existing in the districts from which your correspondents write. Their disappearance is probably due to insect or fungoid parasites, or, as in the case of the black Orchis-moth in Germany, to bacterial agency, which latter appears to be intimately connected with the biological phases of insect life. During the last two or three years the sandy soils round here have been infested with the grubs of the small cockchafer (*Phyllopertha horticola*), which destroy the roots of almost every shallow-rooting plant with which they come in contact. Larch and Scots Fir seedlings have especially suffered, while acres of pasture have been scratched up by rooks and pheasants in search of the grubs during the autumn months. This year the beetles seem more numerous than ever, and numbers of Ash-trees may be noticed almost eaten bare of foliage by them. Fortunately they are less voracious than the May-bug, or the plague would become an absolute calamity. As it is, the roots of perennial plants suffer badly from the grubs during the autumn, and the attack is too widespread, and of such a nature, as to render preventive measures impossible on a large scale. We can only hope for an epidemic to break out amongst them, which will, as it probably has done in the past, reduce their number to the desired extent. *A. C. Forbes.*

BULB MITE.—At Avery Hill, Eltham, the bulb mite infested a great many kinds of plants, and it was present on such diverse subjects as *Primula sinensis alba flore pleno*, *Echeveria farinosa*, *Lobelia cardinalis*, and *Vallota purpurea*, which were so badly infested that they had to be burnt. *Eucharis grandiflora*, *Pancratium*, *Anthuriums*, *Richardias*, *Streptocarpus*, *Caladiums*, *Gloxinias*, *Tulips*, *Snowdrops*, *Narcissus*, *Hyacinths*, were more or less infested, and reduced the numbers from hundreds to dozens, and in some instances all the plants succumbed. It was found that the soil was infested that was employed. [Bulbs and tubers sent by our correspondent were in a hopeless condition from the ravages of the bulb-mite, fully bearing out his statements. Ed.] The remedies that were adopted were as follows: all of the composts used for plants subject to the mite had freshly-slaked chalk-lime mixed with them, this being done some time before using. All sorts of plants do not like lime—but remedy before evil in this case. *Caladiums*, *Gloxinias*, and *Callas*, had black sulphur rubbed into the infested parts also while at rest, as in that condition mites were found on them. For *Vallotas*, *Primulas*, and *Echeverias*, liquid applications are best. *Eucharis* and *Pancratiums* can in every case be completely cured of the mite by the proper use of Cliban's Mite-killer. My method was to make the pot in which the plants was growing water-tight, and continue to fill it with the solution till it would take no more, and allow it to remain at least half-an-hour, and repeat the same process three or four times in twelve months, affording water afterwards at intervals of a fortnight or three weeks, and continuing this year in and year out persistently, and healthy *Eucharis* is certain—at least, such is my experience, the substance being a food for the plants, and death to the pest. All other preventive measures are useless. My experience with other liquids, such as paraffin and lime-water is not hopeful; the former is a failure, as it in time causes a souring of the soil, and it is better for outside use, good results accruing therefrom to *Narcissus* and *Tulips*. Lime-water is a good check to the spread of the bulb mite. *G. A.*

CAMELLIAS OUT-OF-DOORS.—Referring to the note on above signed "W. J. B.," I should like to say that a number of Camellias are planted out in the pleasure-grounds at Bystock, and during the hard winter of 1895, when the common Laurel and *Rhododendron ponticum* were dreadfully cut up, the Camellias did not suffer in the least; the leaves remained plump and green, the buds swelling in the spring just as usual. It was rather singular to notice also that whilst the common *Rhododendron ponticum* was much cut up, losing leaves and appearing shabby till the growing time came on again, the choice varieties that had been worked on the *ponticum* stock stood the weather, and were in no way injured by the severity of the frost or the severity of the east winds. *W. Swan, Exmouth.*

* *Albuca prolifera*, J. H. Wilson, n. sp.—Bulb globose or sub-globose, smooth, deep red, 1 to 1½ in. diam., invariably expanding at one side into a massive sub-cylindrical outgrowth, which bears an offset bulbil; tunics few, 4 to 5, thick; numerous small bulbils borne radially, on short attached stalks, around the base of the parent bulb; the offset bulbil on the shoulder commonly producing a lateral outgrowth with a bulbil, and this in its turn sometimes proliferating; leaves 4, linear, subterete or channelled, longest 12 to 18 in.; inflorescence 12 in.; peduncle 7 to 8 in.; bracts lanceolate, lowest 7 to 9 lines; pedicels erect, lowest 2 to 2½ in.; flowers 3 to 5, very fragrant, odour heliotrope-like; segments pure white, with narrow green median bands; outer segments 9 to 11 lines long, inner 7 to 8; outer stamens fertile, anthers ½ size of inner; ovary 3 lines long, style 4.

Baakens River Valley, Port Elizabeth, Turpie!

CAMELLIAS OUTDOORS.—"W. J. B." puts in a kind word from Kew for Camellias as hardy shrubs. So much have people generally become accustomed to treating these plants as greenhouse shrubs, that they are alarmed at the suggestion to plant outdoors. No one in the kingdom, so far as I know, has ever been braver in this respect than the late Mrs. Eyre Crabbe of Southampton, and her now seed-gardener, Mr. T. Stewart. Mrs. Crabbe, who was a life-long very able gardener, used to refer almost contemptuously to the fears of persons to expose Camellias to outdoor culture. "Why," she would say, "they are hardier than Laurels," because Laurels made their new growths early, and often had them killed by late frosts, whilst Camellias made new growths later, and these escaped harm. Then the old wood and leafage seems impervious to injury from frosts. Many of the huge plants that grow so freely at Glen Eyre, Southampton, and have been planted for periods of from ten to nearly forty years, are fully exposed to the weather, and even to hot sunshine. Others are planted on the margins of shrubberies, or back where they are less exposed to wind and sun; some planted and nailed originally to walls have grown out now densely, and are luxuriant. Anyone at all sceptical as to the fitness of Camellias for outdoor culture should visit Glen Eyre towards the end of April, when the plants are generally in bloom, and they would come away very much less so. The plants there in the blooming season may be said to furnish cart-loads of beautiful flowers. The soil is of a semi-peaty nature, in which Conifers and Rhododendrons thrive luxuriantly, and where trees break the force of north-easterly winds. The three or four large bush Camellias growing at the back of the long corridor house, and in a cold aspect on a stiff soil are remarkable illustrations of the adaptability of these shrubs for outdoor culture in the London district. They are, however, worthy of a better place and superior soil. No doubt when planted it was thought that the foliage would scorch in warm sunshine. It does not do so at Southampton. A. D.

THE GRAFTING OF THE GRAPE-VINE.—In reference to the articles which have appeared in these pages on the Vine and its habit changing under the influence of the stock on which it is grafted, and *vice versa*, it would be interesting to know if the flavour changes as well as the growth. It is just likely that the quality of many of our coarser varieties of Grapes could be greatly improved by a choice of certain stocks upon which to graft. But those who cultivate the Vine extensively will be able to advise on this matter, and many readers of the *Gardeners' Chronicle* will find pleasure and profit from reading such experiences. *Excelsior*.

PEACHES AT CLYNE CASTLE.—On the 14th inst. Mr. Foote was gathering his first Peaches, the variety being Hales' Early. The Peach-houses at Clyne Castle are span-roofed, and the early-house is 50 feet long by 14 feet wide, with a division in the centre. In the first half of this house there are four trees, including one of Hales' Early, one of Elruge Nectarine, and two of Bellegarde Peaches. The trees from which the fruits were being gathered carried some 250 fruits of fine size and quality. The tree of Elruge Nectarine was evenly set with about 300 fine clean fruits. The varieties growing in the second division are Princess of Wales and Lord Palmerston Peaches, with Lord Napier Nectarine, and the trees are well cropped. Mr. Foote lifted the whole of the trees some five years ago, making new borders 18 inches deep on a concrete-bottom. Some of his Princess of Wales Peaches last year weighed 13 oz. R. Milner, Penrice Castle Gardens.

NYMPHÆAS.—The rock-garden at Abbotsbury, Newton Abbot, S. Devon, is just now in splendid condition, for beside the alpine and herbaceous plants, which make a brave show, there is in the ornamental waters a very choice collection of Nymphæas, which at the present time are flowering in a very free and attractive manner. I have before me some flowers just cut and brought in, and as these are but samples of a vast quantity left, some idea may be gathered of this fine display. The first to call attention is N. Marliacea rosea, the largest bloom in the collection; this flower measures, when fully expanded, 9 inches in diameter, and is of a clear rose-blush, which, with stamens of bright yellow, produce a bloom of great beauty and attractiveness. N. Marliacea carnea is also of large size, and of a bright flesh colour. N. Marliacea chromatella is also a noble flower, of a beautiful bright yellow; the leaves also of this one are especially handsome, being spotted and marbled with a bronzy-brown. Another is N. odorata sulphurea, a flower considerably smaller—really a different type; these, however, are very showy, being

FIG. 148.—ALBUCA PROLIFERA: BULB WITH BULBILS.
(Seen from above. Reduced. See p. 396.)

FIG. 149.—ALBUCA PROLIFERA, WITH ROOTING BULBILS.
(Nat. size. See p. 396.)

FIG. 150.—ALBUCA PROLIFERA: UPPER PART OF INFLORESCENCE.
FLOWERS OPEN IN SUNSHINE.
(Nat. size. See p. 396.)

of a bright yellow, the flowers rising several inches above the surface of the water, and are very fragrant. N. pygmaea alba, as its name denotes, is pure white, free in blooming, and very showy. These fine introductions of M. Marliac deserve to be more universally grown than at present would seem to be the case. These at Abbotsbury have been in their present position some four years, and have withstood all weathers in that time without any kind of protection. Doubtless, in time they will become more frequently met with, and if a reference to their beauty and adaptability can help on this desirable end, my note will have answered its purpose. W. Swan, *Exmouth*.

FROST ON JUNE 15.—On the morning of June 15 one of our thermometers, suspended 4 feet above the ground, and fully exposed to the wind, registered 28°, or four degrees of frost. A fine piece of Snowdrop Potatoes was badly injured; but the growing points of the shoots having been uninjured, the tops have not ceased to develop. Some Ashleaf Potatoes, 10 yards away, on a south border, were unharmed. It is interesting to note how a very slight amount of shelter has warded off this frost. Two rows of Scarlet Runner Beans were furnished with stakes placed as usual on each side of the row, and meeting near the top, and of these rows only very few plants are killed; others, alongside of them, but not staked, have about ten times the number killed. Potatoes growing 4 feet away from pyramid Pear-trees, and on the lee side, are unhurt; while the tops of the plants in the next row, 2 feet further away, are cut. Our thermometer, in a Stevenson screen, only registered 33°, which is 5° above the one fully exposed, and the wind was north-east at the time; and this pattern of screen is said to be ventilated on scientific principles. The thermometer on the grass registered 30°. W. H. Divers, *Belvoir Castle Gardens, Grantham*.

FLOWERING AND FOLIAGE TREES AND SHRUBS.—When on the lawn recently at Dover House, Roehampton, I could not fail to notice three very special objects of beauty. The first was a noble and very deep-coloured purple Beech, one of the finest I have yet seen, and standing alone its splendid proportions are fully displayed. The second object was a handsome Judas-tree, then in full bloom, the pleasing soft rosy colour of the flowers, borne in rich profusion, not being a common hue in flowering-trees. Thirdly, on a wall, set in a dense framework of Magnolia and other green leafage, is a plant of Viburnum plicatum, literally a mass of white clusters of flowers. There is a smaller one at Chiswick also on a wall. Both are beautiful plants in that form of culture, and beds of it at Kew are masses of snowy flowers. A. D.

THE GARDEN CHARITIES.—Mr. Fletcher heads his note as above, and then goes on to discuss the advantages to be gained by subscribers in a truly mercenary spirit; and it is evident that if the subscribers are all of them to contribute to the various funds, from his point of view, the societies will cease to be "charities" altogether. I have read that we are to "lend, hoping for nothing again," also that "the quality of mercy is not strained, it droppeth as the gentle rain from heaven," and to coldly calculate how much each subscriber is to get out of the society is scarcely in accordance with these high precepts. The Gardeners' Orphan Fund is evidently alluded to, although no names are mentioned; but this fund is certainly not open to the charge of expensive management. It has no palatial offices, nor does it pay high salaries, and the whole expenses of collection and distribution are less than 12 per cent. of the money subscribed. It was instituted by the gardeners and horticulturists of Great Britain as a charity, and as a means of helping the children of their brethren in the profession, who might unfortunately be left without a father, not for the purpose of trying how much each subscriber could get out of it. I cannot think Mr. Fletcher is a gardener, or he would not make such statements as to a gardener's means, while I heartily wish every gardener had double his present wages. I speak from experience when I say that 90 per cent. of the gardeners who are in head places could easily lay by 1½d. per week for the Gardeners' Orphan Fund, and would not miss it at the end of the year; but when it comes to paying 5s. out of pocket all at once, it is sometimes more difficult. The Gardeners' Orphan Fund has done, and is still doing, a good work; none of the money subscribed is wasted, and if Mr. Fletcher will send in his name as a subscriber, he may yet

learn, "Blessed is he who considereth the poor and needy." W. H. Divers, Belvoir Castle Gardens, Grantham.

LAW NOTES.

THE WARRANTY CLAUSE.

HOWCROFT v. LAYCOCK.

THIS action, which came on for hearing in the Queen's Bench Division of the High Court of Justice, before Justices Day and Lawrence, was an appeal from the decision of his Honour Judge Lumley Smith, reported in these columns on April 30, raising a question with regard to the effect of a clause very commonly put at the head of seed-merchants bills. The clause was as follows:—"Messrs. — give no warranty, express or implied, as to description, quality, productiveness, or any other matter connected with the seeds they send out, and they will not be in any way responsible for the crop. If the purchaser does not accept the goods on these terms, they are to be at once returned." The evidence was to the effect that the plaintiffs had supplied some seed to the defendant's order. The order was for a species of Cabbage called Couve Tronchuda. The seed sent, when it grew, turned out to be Jersey Kale, a species of tree Cabbage, only suitable for making walking-sticks. The action was brought for the price of the seeds, and the defendant counter-claimed for breach of contract. The County Court Judge thought that the non-guarantee clause protected the plaintiffs, and but for that, he would have found for the defendant. Mr. Earle, on behalf of the plaintiff, contended that when in ordinary cases goods have been accepted, the purchaser could only recover for breach of warranty, but here the purchaser had agreed not to raise any question of warranty, and therefore he had no remedy. It was an important matter for the seed-seller and for seed-growers all over the country. In this case the seed-seller had bought the seed from someone else, so that there was no imputation as to their *bona fides*. Seed would be very much dearer if the sellers had to guarantee it. Mr. Justice Day was of opinion that the County Court judge had been misled by a case which had no bearing on the question. The clause in question could not be construed to mean that no action should be brought. When Couve Tronchuda was ordered, the seed-sellers were not entitled to deliver something quite different. The custom of a trade might qualify a contract, but it could not destroy it. A rational construction must be put upon the words relied upon. The construction desired by the respondents to be established, was unreasonable. Mr. Justice Lawrence concurred, consequently the appeal was upheld. Leave to appeal was granted, if an indemnity as to costs were given by the plaintiff.

Obituary.

MR. THOMAS MARCH.—The recent death of this gentleman, who occupied the responsible position of Secretary to the Board of Green Cloth, and who had been in the service of King William IV., and of Her Majesty, during sixty-four years, recalls to mind the March flower-stands, designed by Mr. March, and very much used in the sixties and onwards at the Royal Horticultural Society's exhibitions, South Kensington, and elsewhere. The Queen, the *Court Circular* notes, much regrets the loss of an old and trusted official, who for many years had rendered valued service in positions of great responsibility in the royal household. *J. B.*

PROFESSOR ANTON KERNER RITTER VON MARILAU.—The death of Prof. Anton Kerner Ritter von Marilaun is announced at the age of sixty-seven. Professor Kerner was educated for a doctor, and was indeed for two years on the medical staff of the Vienna General Hospital. But he soon abandoned medicine for the pursuit in which he was to acquire fame. He wrote many works on botanical subjects, and was made a member of the Vienna Academy of Sciences in 1872, while he received the order of knighthood in 1876. He is best known in this country by his *Natural History of Plants*, the English edition of which was edited by Professor F. W. Oliver, M.A., D.Sc.

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

JUNE 14.—J. T. BENNETT-POE, Esq., in the Chair.

"Silver" Leaf Disease.—Specimens of this disease on Plum-trees were received from Mrs. Floyer, Basingstoke. The disease is known to be very common on Pomaceous plants, the silvery appearance being due to the raising of the epidermis from the underlying tissue. The disease is very fatal both indoors and out, and is in all probability attributable to the growth of a fungus, the nature of which has not yet been ascertained.

Apple-leaves.—Some leaves probably injured by frost or scald from the effect of the sun shining on a damp surface were also sent.

Plant Diseases.—Dr. William G. Smith reports as follows on the specimens submitted to him:—

Peonia Disease.—From a further specimen of this disease I have confirmed my previous opinion. The latest specimen sent bore the fructifications of a fungus which I hope to have identified. The diseased tissues contain abundant mycelium, and the starting point for attack was from last year's old wood. I shall be glad to communicate further results later.

Begonia-leaves.—From the material sent by Mr. Caddy it was difficult to say really what was the cause of disease. One or more fungi were easily developed on the withering leaves, but whether these were saprophytic on the dying tissue or were the cause of trouble, it is not safe to say. Begonias of this class are so liable to wither at the margins (from draughts, &c.), and are so unsuitable for transit to a distance, that accurate observation can only be made on plants in their actual habitat.

Fungus on Thuya (Biota).—The plants sent were attacked by *Pestalozzia funerea*, Desm., a fungus well known to occur on dying Thuyas and allies. The life-history is, however, imperfect.

Cytisus Adami.—Mr. Herbert E. Brooks sent specimens of the curious *Cytisus Adami*, a well-known "graft hybrid," as it is supposed to be, for M. Adam budded *C. purpureus* on *C. Laburnum* in 1825. The purple and yellow flowers are of the true species, but the brick-red flowers are from the hybrid. It was described in the *Gardeners' Chronicle*, 1841, p. 325, 336; 1842, p. 397, and often subsequently. The fullest account is in Braun's *Rejuvenescence*, 1851 (English translation, 1853); in Prof. Morren's paper in the *Belgique Horticole*, 1871; and a summary of the whole subject is given in Darwin's *Variation of Animals and Plants*, vol. i., ed. 2 (1875), p. 413.

LINNEAN.

JUNE 16.—Dr. A. GÜNTHER, F.R.S., President, in the Chair.

Professor A. G. Farmer, F.L.S., and Mr. W. G. Freeman, F.L.S., demonstrated the action of germinating Peas, Cress, and Barley, in causing the deoxidation of a watery solution of methylene-blue to a colourless liquid on shaking up the latter with air, while on adding a drop of hydrogen peroxide the blue colour was restored. Green plants placed in the solution were found to act in a manner precisely similar to the seedlings, though the action may be modified by assimilation in sufficient light. A number of experiments were shown.

A discussion followed, in which Mr. Bennett, Professor Howes, and Mr. Thomas Christy took part.

Mr. F. Enoch, F.L.S., exhibited and made remarks on the eggs of an Hemipterous insect containing living parasites (*Prestwichia aquatica*), of whose life-history and habits he gave a detailed account.

Professor Herdman, D.Sc., F.R.S., exhibited some dissections, microscopic preparations, and drawings, to illustrate the presence of modified pedal-muscles in the oyster.

Mr. Miller Christy, F.L.S., read a paper entitled, "Observations on the Seasonal Variations of Elevation in a Branch of a Horse-chestnut Tree."

A paper was read by Mr. G. W. Carpenter, B.Sc., "On Pantopoda Collected by Mr. W. S. Bruce in Franz-Josef Land," in which he recorded the existence of eleven species, one of which he described as new. Of this, *Nymphon piliferum*, a detailed description was given; as of a new variety, *Nymphon piliferum* var. *abbreviatum*.

A paper was read by Mr. J. E. Duerden "On the Morphological Relationship of the Actiniaria and Madreporaria."

Dr. C. Forsyth-Major communicated a paper "On some Fossil Leporines," an abstract of which was given by Professor Howes.

At the conclusion of the proceedings, the President referred to the loss which the Society had sustained by the recent death of Mr. Osbert Salvin, M.A., F.R.S., F.L.S., a member of the Council; and announced that a special general meeting would be held on June 30 for the purpose of electing a new Member of Council to fill the vacancy thus created.

EDINBURGH FIELD NATURALISTS' AND MICROSCOPICAL.

LAST Saturday, June 18, this Society had a joint excursion with the Kirkcaldy naturalists to the Island of Inchcolm.

The party numbering forty, after visiting the remains of the old monastery and the little stone-roofed building identi-

fied by Sir James Y. Simpson as the hermitage of King Alexander I., and said to be the oldest stone building in Scotland, examined the flora and geology of the island. Most of the plants are uncommon, and such as would likely be used by the monks for culinary or medicinal purposes. Among the most noticeable were *Verbascum thapsus*, *Conium maculatum*, *Artemisia absinthium*, *Ligustrum scoticum*, *Anchusa sempervirens*, *Atriplex arenaria* (*Atropa belladonna* and *Hyoscyamus niger*, though said to be on the island, were not found). Many of these plants are still used medicinally. *Verbascum thapsus* having again recently attained a reputation as a remedy for phthisis. The geologists collected a number of specimens of picrite, a rock resembling a dark coloured green stone in appearance, and consisting very largely of olivine. There are only two localities near Edinburgh where this rock is found, viz., at Blackburn near Bathgate, and on the Island of Inchcolm, where it was discovered in 1880 by Sir Archibald Geikie.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JUNE 16.—The Members of the Committee present on this occasion were Mr. W. Thompson, chairman, Mr. G. S. Ball, vice-chairman, Messrs. S. Gratrix, A. Warburton, J. Leemann, H. Bolton, W. Holmes, P. Weathers, Thos. Mills (Hon. Sec.). This was undoubtedly the best show yet brought together since the formation of the Society, no fewer than three very praiseworthy groups being staged by amateurs.

Mr. A. WARBURTON, Haslingden (gr., Mr. T. Lofthouse), had one of the best in point of size and richness, in which were included such choice things as *Odontoglossum excellens* var. Thompsoni, with a spike carrying twenty-two flowers, *O. Vuylstekianum*, which is a yellow form of *O. luteo-purpureum*, with fifteen flowers, *Laelia purpurata* Backhouseana, a very handsome form, with petals having dark-coloured stripes, *Laelio-Cattleya* × "Bertie Warburton," the parentage of which is doubtful, but which may be *L. purpurata* × *Mossiae*, of which other hybrids are known, was a conspicuous plant in the group. There was also a magnificent specimen of *Brassia verrucosa* with twelve enormous flower-spikes, which, if not the most valuable, was certainly one of the most beautiful subjects in this interesting group. Other good things were *Laelia purpurata* var. *fastuosa*, *Cattleya Mendeli* var. *Aurora*, the latter having pure white sepals and petals with a streak of almost purplish-blue running through the centre of either petal. *Laelio-Cattleya* × *Lady Wigan*, *L.-C.* × *Iolanthe*, *L. purpurata* Hardyana, a good strain of *Cattleya Mossiae*, a well-grown piece of *Dendrobium Jamesianum*, *Epidendrum vitellinum* majus, and some remarkably good *Thunias* were included in this group (Silver Medal).

Mr. JOHN LEEMANN, Heaton Mersey (gr., Mr. Edge), also staged a fine group of plants, consisting of fine *Cattleyas*, *Odontoglossums*, *Dendrobiums*, and *Cypripediums*. One of the finest things undoubtedly was his *Odontoglossum crispum* var. *grandiflorum*; the flowers were rather over 4 inches in diameter, of remarkable substance, the purest of white, and of the form accepted by connoisseurs to be the best. Another good plant in this group was *Cypripedium Goweri*, a form very rich in the colouring of the dorsal sepal. *Cattleya Mossiae* grandiflora, notable for its fine size and colouring; *Odontoglossum Wilckeanum* var. *nobilior*, with a fine spike of rather pale flowers. A Silver Medal was also awarded to this group.

Mr. G. SHORLAND BALL, Wilmslow (gr., Mr. Hay), staged a nice interesting group of plants, the most notable of which were two wonderful specimens of *Dendrobium Falconeri*, bearing over 700 flowers between them; both plants were perfect pictures, and if Mr. Hay can continue the successful cultivation of this difficult subject, he should be congratulated. An interesting plant was a species of *Zygopetalum*, which was introduced in an importation of *Cattleyas*, doubtless one, a *Pescatorea*, now placed under *Zygopetalum*. It is a very handsome flower, possessing a creamy ground with reddish-brown markings. There were also some well-grown *Dendrobium Dearei*, *D. Jamesianum*, and a very pale variety of *Cypripedium Curtisii*.

Mr. S. GRATRICK, Whalley Range (gr., Mr. McLeod), showed a very interesting form of *Cypripedium Lawrenceanum*, which at a first glance strikes one as *C. L. Hyeanaum*, but it differs entirely in the petals, it has none of the warts visible in that variety, and is peculiarly striated with a dullish white and green; this seems to be quite a new feature in *C. Lawrenceanum*, and the plant is undoubtedly a valuable acquisition. *Cattleya Mossiae* var. "Cahuzac" and *C. M. Rappartiana* came from the same collection.

MESSRS. F. SANDER & Co. sent two good hybrids, viz., *Laelio-Cattleya* × "Duke of York," a lovely thing between a fine form of *L. elegans* × *Cattleya Brymeriana*, the latter itself a hybrid between *C. Eldorada* × *C. superba*—the colouring is of rich purple, and the flower well shaped and compact; and *L.-C.* × "Lily Measures," another product from an artificial and a natural hybrid, viz., *L. Arnoldiana* × *L. Gottoiana*.

MESSRS. STANLEY MOBBS & ASHTON made their debut as a new trading firm. Mr. Ashton was until recently the managing partner of Messrs. W. L. Lewis & Co., of Southgate; he has now, in conjunction with Mr. Stanley Mobbs, taken over the business, and will no doubt make headway, especially if the quality of their goods are equal to those shown at Manchester. From this firm came a splendid collection of their strain of *Cattleya Mossiae*, all good and worth showing, the best being *Cattleya Mossiae* "Sir Thomas

Lipton," named, I believe, after a new patron of Orchid-culture. Th's variety belongs to the Reineckiana section, but is quite distinct in the lip, having a striking break in the colouring, and the flower is of massive proportions.

Messrs. LINDEN, Brussels, were again to the fore with good Odontoglossums, *O. crispum* "Morning Star" being a very charming variety. The segments have large blotches, punctured all round with tiny spots. *O. crispum* "Le Czar" is also a good form, with large blotches on the sepals only. *O. crispum* Dallemagne, a very heavily-blotched variety.

AWARDS.

First-class Certificate.

G. Shorland Ball, Esq., for *Zygopetalum* species.
Messrs. F. Sander & Co., for *L.C. Duke of York*.
Duncan Gilmour, Esq., for *Cattleya Mossiae Wagneri*.
Wm. Bolton, Esq., for *Cattleya Mossiae Rappartian*.
M. L. Linden et Cie., for *Odontoglossum crispum* "Morning Star".
J. Warburton, Esq., for *Laelio-Cattleya Bertie Warburton* and *Odontoglossum Vuylstekianum*.

Award of Merit.

John Leemann, Esq., for *Cypripedium Goweri*, *Odontoglossum crispum grandiflorum*, *O. crispum* (no varietal name), *O. Wilckeanum nobiliss*, *Laelio-Cattleya* × *Canhamiana*, and *Cypripedium Mendeli*.

Messrs. Stanley Mobbs & Ashton, for *Cattleya Mossiae Sir* os. Lipton.

Duncan Gilmour, Esq., for *Cattleya Mossiae Joan of Arc*.

Wm. Bolton, Esq., for *Cattleya Mossiae Mrs. Bolton*.

M. L. Linden et Cie., for *Odontoglossum crispum* Le Czar and *O. c. Dallemagne*.

Samuel Gratrix, Esq., for *Cypripedium Lawrenceanum* Gratrixianum and *Cattleya Mossiae Cahuzac*.

A. Warburton, Esq., for *Laelia purpurata* var. *fastuosa*, *O. p. Backhouseana*, and *Odontoglossum excellens* Thompsoni.

Cultural Certificate.

G. S. Ball, Esq., for *Dendrobium Falconeri*.

Vote of Thanks.

Messrs. Stanley Mobbs & Ashton, for group.

S. Hinchcliffe, Esq., for a wonderful form of *Dendrobium Dalhousieanum*. P. W.

NEWCASTLE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT.

JUNE 14.—The usual meeting of this Society was held at 25, Westgate Road, on the above date. The chair was taken by Mr. JAMES NICHOLSON, and there was an excellent attendance of members.

The monthly competition was for Gloxinias, which was won by Mr. JAMES RENWICK, Oakwood, who staged a pair of very creditable plants. Mr. LEONARD, Gateshead, read a very interesting paper on "The roots of plants and how they feed," which was followed by a discussion, in which many took part.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

JUNE 20.—The second meeting of the summer session of the above was held in the Club-room on the above date, when Mr. TURTON, the Chairman of the Association, presided over a good attendance of members.

The subject chosen for the evening was "vegetables in season," introduced by Mr. H. Wilson, gr. to Mrs. Bland-Garland, Lower Redlands, Reading. The varieties principally touched upon were Asparagus, Cabbage, Carrots, Mushrooms, Tomatos, Turnips, French Beans, Vegetable-Marrows, Peas, Lettuce, Broad Beans, Cucumbers, and Potatos. A profitable discussion took place, some fifteen to twenty members giving their experience with regard to the various kinds referred to.

Some exhibits came from Mr. Townsend, gr. to Sir W. FARRER, Sandhurst Lodge, consisting of tropical and hardy Nymphaeas. Mr. WILSON showed excellent specimens of Sutton's First-crop Cauliflower, Snowball Turnip, Champion Horn Carrot, and several Lettuces. Mr. TURTON, gr. to Maiden Erlegh, showed a good sample of Ringleader Potato; Mr. Smith, gr. to Miss NIELD, Greenbank, nine bunches of Pansies, distinct varieties; Mr. OSBORNE, jun., a plant of *Streptocarpus*, a cross between *S. Wendlandi* and one of the hybrid strain.

SHIRLEY AND SURROUNDING DISTRICT GARDENERS' AND AMATEURS' MUTUAL IMPROVEMENT.

JUNE 21.—The monthly meeting of the above Society was held at the Parish Room, Shirley, Southampton, on the above date, the evening being a fair attendance of the members; the president, W. F. G. SPRANGER, Esq., presided.

FRANK PERKINS, Esq., M.R.A.C., gave an interesting lecture entitled "Some Asiatic Plants noticed in the course of travels in Japan, China, and Ceylon," the same being most profusely illustrated with lantern views of tropical vegetation, giving one an admirable idea of the gigantic proportions the vegetation of that part of the world attains to. The lecturer's remarks on Tea, Coffee, and spice plantations in Ceylon were especially interesting, showing the advance made there in the

culture of Tea, especially during the past few years. He also turned his attention to the Palms, Bananas, &c., the slides helping to give point to the remarks on their elegance and stature.

A vote of thanks was accorded to Mr. PERKINS at the close of the lecture.

There was a good display of Roses sent by Mr. W. H. ROGER, Red Lodge Nursery.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

DEVON AND EXETER AUXILIARY.—President, C. R. COLLINS, Esq., Hartwell House, Exeter.

The Committee, in presenting their report for the past two years, beg to thank the various subscribers for their valued support, to tender their sincere thanks to the Right Worshipful the Mayor of Exeter for the use of the Guildhall for the inaugural meeting, and for the great interest his worship and the sheriff took in making it such a success; and to thank the Secretary and members of the Devon and Exeter Horticultural Society for the permission to hold a stall at their summer show of 1896, which resulted in a profit of £15 2s. 7d.; at the same time they regret it was found impossible to grant permission to hold it the next year. The best thanks of the committee are also due to Madame Bryce and her lady assistants for the great interest they took in the management of the stall, and the able manner in which they carried out the work connected with it, and to the generous donors of fruit, flowers, &c., for the stall. The committee cannot but express their disappointment in the manner in which support has generally been accorded to the Society in Devonshire, and would again point out the great advantage it is to a gardener to become a subscriber, especially to one who subscribes early in life; and also to ask the help and sympathy of those who can afford to lend a helping hand to so deserving a cause. A society such as this should recommend itself to all gardeners, and to all lovers of horticulture.

As will be seen by the balance sheet, the first year resulted in the addition of thirteen new subscribers, and enabled the local Society to make one Life Member by ballot. The second year two new subscribers were added and two ballots taken, one of which was not taken up, but the member has become an annual subscriber. The Society is now in a position to take a further ballot, and will do so at once; members should therefore send in their subscriptions immediately, to enable them to participate. Of the balance in hand £22 will be at once handed over to the parent Society, W. Mackay, Hon. S. C. and Treasurer, 26, High Street, and Royal Nurseries, Exeter.

This branch of the Institution has been formed for the purpose of diffusing information regarding its work amongst gardeners, market gardeners, nurserymen and seedsmen, and to bring more prominently before those interested in horticulture, and the benevolent public in Devonshire, its claims for increased support; and also to help forward the candidature of any distressed applicant from the county.

Amongst the pensioners now on the funds are three who reside in the city of Exeter.

CHISWICK GARDENERS' MUTUAL IMPROVEMENT.

The members of this society, which includes in its range not a few of the Kew students, as well as those of the Royal Horticultural Society's Gardens, and gardeners of the locality, have been specially favoured by the Rev. George Henslow with hearing a course of four lectures, the first of which was given in the great Vinery in the gardens on the evening of Wednesday, the 8th, the subject being "Vegetable Physiology." The attendance numbered nearly sixty, and included three lady students from Kew. Mr. W. MARSHALL, member of the

Royal Horticultural Society's Council, presided. Admirable as was the place of lecture, sound was somewhat marred by that inveterate echo which seems ever present when the voice is raised in that huge building. Still, every one could hear the lecturer fairly well. Generally, the address dealt with various points in the subject of physiology, as these were not essentially connected, yet the seed of a plant, its formation, essentials to promote germination, air, warmth, moisture, the inevitable tendency of the radicle to grow earthwards, and the plumule upwards to the light, were well explained. The nature and functions of the root-cap and of the root-hairs were also shown, being especially aided by excellent drawings. Diverse forms and habits of roots were described. Leaves and their functions, respiratory powers, exhalation of oxygen, and absorption of carbonic-acid gas, led up to an interesting exposition of the results of experiments with divers coloured glass on seed-germination and plant-growth.

The lecture was followed with close interest, many present taking notes; and it is believed that when the next Royal Horticultural Society's examination takes place, the Society will furnish a large body of candidates.

Mr. Henslow's lecture on Wednesday last was on "The origin of diverse garden vegetables."

ENQUIRY.

VAPORISATION WITH "XL ALL."—A correspondent "B. W." would be obliged if some of our correspondents would kindly inform him of the action of the XL-all vaporiser on Muscat of Alexandria Vines. What stage of growth the berries were in at the time it was used, and if any harm followed. Whether Black Hamburg Vines can be vaporised with XL all at any stage of growth.

AZALEA INDICA, FROM THE OPEN GROUND.—We have lately received from Mr. Foote, gardener to W. G. Vivian, Esq., Clyne Castle, Swansea, a quantity of sprays of *Azalea indica* in variety, all very lovely, which had been taken from bushes planted out-of-doors at that place. The blooms were evidently produced abundantly, and they were of fair size. Gardeners do not as yet seem to recognise the usefulness of *Azalea indica*, in all its varieties, as a subject for the American garden in the milder parts of Britain. (See note on p. 392.)

NOTICES TO CORRESPONDENTS.

ANTS IN A PEACH-BORDER: T. H. You might destroy them by puffing the fumes of Richards' XL All into their holes with a pair of fumigating-bellows, allowing the stuff to form a vapour in an almost close box, and drawing it up with the bellows, and discharging it into the ant's holes, which should be then closed with soil, &c. Rags dipped in petroleum and stuffed into the holes would drive them away, and shavings dipped in gas-tar and laid along at the foot of the wall would have the same effect.

ATLAS CEDAR: W. The leaves of the Cedar or Deodar, though called evergreen, are only relatively so, they fall off after a few years, and if they happen to do so before the new ones are formed, the tree has a bare appearance. There is nothing to cause apprehension about your tree. It will resume its beautiful appearance later on.

CUCUMBER: Gilbert. The roots of your plants are infested with eel-worms, minute creatures that require a microscope to enable you to see them. They come in the soil, so your only remedy is to destroy your plants by fire, and start afresh with fresh soil which you will do well to bake before using, or sterilise it by pouring boiling water on it.

CUCUMBERS: H. J. C. The first stopping of the stem should take place when the latter has got 6 inches higher than the trellis. This will give you from four to six shoots that will form the ground-work of your plant; and each of these shoots may be stopped once more when they have got half-way to the margin of the trellis. No fruits that show need be removed unless very numerous or deformed. The same kind of training and stopping holds good of plants running on the soil in a hot-bed, pegs being used instead of ties to keep the plants in place, and each shoot by forming roots in the soil at the pegged parts is made an independent plant. Hence Cucumber plants cultivated in that manner are longer lived than trellis plants. After a plant has borne fruits for some months it becomes exhausted, but it may have its vitality renewed by severely cutting back the old bine, and by affording

top-dressings of fresh horse dung and loam. This kind of renewal is also carried out during bearing by the removal of the oldest and least fruitful parts of the bine, and laying in new shoots. When fruits come on short side-shoots, the latter may be stopped one or two leaves in front of a fruit, although we do not think much good results from doing so. When, on the contrary, fruits show on a main-shoot, no stopping can necessarily be done, and yet the fruits grow to perfection. Excessive stopping leads to a multiplicity of useless shoots and leaves, and considerable subsequent mutilation of the plant. It may sometimes occur that Cucumber-plants have to be lead along one or two lengths of wire at the back of a plant or pine-stove, or pit; and in that case the plant is stopped once when it reaches the wires, and one or two shoots are taken to the left and the right hand. Such shoots may be stopped at every 3 feet, and the laterals allowed to droop.

CUSTARD-APPLE: *T. R.* As you do not know the species of Anona of which you possess seedlings, it will not pay to continue to grow them. The best fruiting species grow into bushes or small trees from 10 to 15 feet in height.

DEATH OF GOOSEBERRY-BUSHES WHOLLY OR IN PART: *T. R.* Sometimes "red-rot" is the cause, and then their destruction is very rapid; at other times it is brought about by a fungus, *Polyporus ribis*, which appears at the lower end of the stem. It is woody, in colour red-brown, of irregular shape, and 4 to 5 inches across. A white aphid, with a wax-like coat, sucks the roots (*Schizoneura grossulariae*, Schüle). You will have to ascertain which of these is causing the loss of the bushes. In the above cases of disease there is no known cure.

DISEASED PEAS: *Cymro.* The plants sent are attacked by a mildew-fungus. The fact that other varieties near them are quite healthy indicates that your soil is too stiff, or in some other way unsuitable for this particular variety. The "clubbing" of Brussels Sprouts has nothing to do with this fungus on the Peas; both diseases are probably due to defective drainage of the stiff clay.

DOUBLE-FLOWERED APPLE: *J. B.* An excellent specimen of a not uncommon occurrence (see fig. 151). You will see first of all that the growth is of this season—a mid-summer shoot—the flower-stalk does not expand into an Apple or pome, the five sepals are perfect, and there are numerous white petals, some few malformed stamens, and no fruit. The specimen is very interesting, but not to the fruit grower.

DRIED PLANTS: *J. H. M.* Judging from your description the specimens are of little or no value as botanical specimens. As fancy articles for bazaars or similar purposes, they might be of service. No. III. is the most valuable, according to your account.

ERRATA: HORTICULTURAL SHOW AT PENZANCE. See our last issue. Instead of Mr. G. Brann, Senr., gardener to J. Branwell, Esq., read Mr. G. Brann, Senr., gardener to Thos. Branwell, Junr., Esq., Penzance.

GARDENERS' BENEFIT SOCIETY: *A. B. C.* The secretary of this excellent and economically-managed benefit society is Mr. W. Collins, and his address, 9, Martindale Road, Balham, London, S.W.

INSECT IN PEAR: *Edward Mann.* *Anthonomus pomorum*, Apple and Pear weevil. Use grease-bands on the stems as for winter moth, to prevent the females climbing into the trees; scrape off all rough bark, and catch the weevils by spreading a sheet beneath the tree, and tapping the latter smartly to cause the insects to fall, which they do quite readily. Remove the upper crust of soil beneath the trees, and bury it deeply elsewhere.

MANURES: *Experimental Student.* Question 1. Can I mix superphosphate of lime with superphosphate of bone together without any chemical action ensuing; if so, may I add to the mixture sulphate of ammonia and sulphate of potash? *Answer.* If both the mineral superphosphate and the raw bone superphosphate are well made (that is say, if obtained from a reliable firm) there can be no ill-effects from the mixing of the two together, although there may be a slight loss of plant-food. What happens is this—a certain quantity of the ammonia which is produced by the decomposition of the ossein of the bone combines with some of the soluble phosphoric acid previously formed, with the result that the phosphate of ammonia reacts upon some of the sulphate of lime in the

mixture, and leads to the formation of a quantity of insoluble phosphate of lime equivalent to the amount of ammonia evolved. A very cheap mineral superphosphate, containing much free sulphuric acid, should be avoided for mixing with bone.—*Question 2.* I know I can mix either sulphate of ammonia or potash with lime superphosphate, but am told that I cannot mix lime superphosphate with pure raw bones, but that I may mix lime superphosphate with bone superphosphate. *Answer.* The same thing happens, but in an aggravated form, when sulphate of ammonia is mixed with free sulphuric acid found in the poorer classes of mineral superphosphates. No change will be made in the sulphate of potash.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*W. H. D.* 2, *Veronica Teucrium* var. *alba*; 3, *Crambe cordifolia*.—*Claud Lonsdale.* The shrub is a species of *Cornus*, and the herb a species of *Stachys*, probably *sylvatica*. Send when in flower.—*E. Lonicera.* A form of *Centaurea calcitrapa*, with an abortive flower-head.—*C. Jones.* Without seeing the leaves the Saxifrage cannot be identified.—*C. A. B.* 1, *Tradescantia virginica*, white var.; 2, *Ranunculus acris*, double fl.; 3, *Stenactis speciosa*; 4, *Thalictrum aquilegifolium*; 5, *Polemonium coeruleum*, white var.; 6, *Hemerocallis flava*.—*W. K.* 1, *Cotoneaster affinis*; 2, *Calycanthus floridus*; 3, *Spiraea arifolia*; 4, *Lonicera*? 5, *Buddleia globosa*; 6, *Olearia Haasti*, all wretched specimens.—*A Price's Candle-box* has been received with no name of the sender, and no numbers attached to the specimens. One is *Hes-*

ture from 15° to 20° below the prevailing warmth of such a house. The plant would do better in a common garden-frame, placed over an excavated space, say, one foot deep, with a provision for affording air near the ground level, the frame being placed on the north side of a building or high wall.

PEACHES: *T. F.* The Peaches sent were of large size, and good eating, despite the comparative absence of colour in the skin from having been borne on a shaded part of the trellis.

PROLIFEROUS ROSES: *C. B.* These are not uncommon. The flower is a branch, and sometimes it produces additional terminal and side branches, and these are prolific roses.

RUST ON THE LOGAN-BERRY: *R. B. F.* The same *Aecidium* which infests the Rose; and the same means as gardeners adopt to rid their bushes of this beautiful but injurious pest must be taken.

TOMATOS: *Burns, Chichester.* Your fruits are affected with "spot," caused by the fungus *Cladosporium*. Remove every fruit attacked, and burn as soon as the circumstance is observed. Why the fruits generally are small we cannot advise you; but it must be due to certain details in your cultivation being defective.—*Amateur.* In your case the trouble is due to the fungus *Peronospora*, similar to that which attacks the Potato. Remove and burn every leaf attacked, and afterwards, provided the fruits are not near ripening, spray the whole of the plants with the Bordeaux Mixture.

VINE: *Amateur.* If you train the Vine on what is

FIG. 151.—A DOUBLE-FLOWERED APPLE.
(See *J. B.* in "Answers to Correspondents.")

peris matronalis, the single-flowered Rocket, *Spiraea media*, and two Medlars or species of *Crataegus* closely allied.—*J. C.* *Listera ovata*, the cut-leaved Lime.—*S. M.* *Adiantum capillus veneris* *Daphnites*.—*W. T. N.* *Scilla peruviana* of gardens, not a native of Britain nor of Peru, but the name cannot be changed now.—*E. S. R.* 1, Spanish Iris, which we cannot name; 2, *Iris graminifolia*; 3, *Lilium umbellatum*; 4, seedling Iris, which we cannot name; 5, *Veronica gentianoides*; 6, *Lonicera sempervirens*; 7, *Helianthemum* sp.—*A. S. C. J.* 1, *Asplenium marinum*; 2 and 4, *Lastrea dilatata*; 3, *Athyrium filix-femina*.

NATIONAL DAHLIA SOCIETY: *Kent.* T. W. Girdlestone, Esq., Sunningdale, Berks, is the secretary. Dahlias are shown at most autumn provincial shows, the dates of which will be given in advance in these columns. As a Kent gardener it should be an easy matter to ascertain the dates of those occurring in that county.

ORCHIDS BOUGHT IN BUD FLOWERING IN A GREENHOUSE: *Amateur.* *Dendrobium nobile*, *Lycaste Skinneri*, and *Cattleya Mossiae*, *C. Trianae*, *C. labiata* and others from sub-tropical regions would flower in the greenhouse, but you could not hope to keep them there afterwards in a good state of health. If you could by means of garden-mats, oiled canvas, &c., screen off a part of the greenhouse, and keep it 5° to 6° warmer, and moister than the other part of the house, you could keep these plants there till October. *Odontoglossum crispum* would get into bad health owing to the high degree of warmth of the greenhouse in the summer months, its needs demanding a tempera-

termed "short-spur method," the lateral or side-shoots will be 9 inches to a foot apart; and should not be closer than the first-named. If the space between the rods is 4 feet, the laterals may extend at right angles to the rods till they meet, and then be stopped. That is for Vines before they come into bearing. The laterals that bear bunches are stopped at one joint before the bunch, and in all cases the minor shoots that spring from the laterals must be nipped off at the first leaf. The rod should not be stopped if it be a young one, but allowed to grow on, getting it up to the light, if you can, or fastening it to the wall at the back of the vinery. In fruiting rods it is usual to prevent the growth of the end till the fruit is ripe, and then let it go, as well as allow some little freedom of growth in the laterals. The temperature at night may now be 60°, and by day anything between 65° and 85°, with air given by 7 A.M., and the amount of air increased hourly up to 11 or 12 o'clock, unless the day be cool, when but little air may be afforded. Close the vinery at 3 P.M., damping the floors, walls, &c., and at 8 P.M. open the upper lights an inch or so. Purchase some manual on Vine culture.
